The Thomist reaction has had a good effect in the way of encouraging the study of Aristotelian philosophy in itself, and as modified by Aquinas. Nevertheless, the world cannot afford to surrender itself to the author. Aristotle is, of course, a great master, both physically, about Nature to understand its matter, or its motions, or its forces; and consequently he fell into the error of supposing a primary matter with four contrary primary qualities, hot and cold, dry and moist, forming by their combinations four simple bodies, earth, water, fire and air, with natural rectilinear motions to or from the centre of the earth; to which he added a quiescence of ether composing the stars, with a natural circular motion round the earth. Metaphysically, he did not, indeed, as is often supposed, think the nature of substance to be matter and form, because in his view God is a substance, yet with no matter; but he did think that every natural object is composed of a common substance, a form different from matter. He thought that besides proximate matter, or one body as matter of another, there is a primary formless matter beneath all bodies, capable of becoming all in turn, but itself, on the contrary, not actually, substance. He thought that, if a form, or essence, is something different from, and at most conjoined with, matter in a concrete body, but also that in all the bodies of one kind, e.g. in all men, there is one indivisible form or essence, which differentiates two members of the kind, e.g. Socrates and Callias, is their one form or essence only as conjoined with different matters, e.g. different bones and flesh. He thought, moreover, that the identity of the matter of an original essence is unchangeable; and, in order to avoid the "separate forms" supposed by Plato, he concluded that the world of Nature must be eternal, in order that each original essence may from eternity always be in some individual or another of its kind. On this assumption of the eternity of the world, God could not be a Creator. Aristotle thought that God is only prime mover, and that too only as the good form, in which all things have form; so that God moves as moves. Psychologically, Aristotle applied his dualism of matter and form to explain the antithesis of body and soul, so that the soul is the form, or entelechy, of an organic body, and he applied the same dualism to the external world, in which a material (i.e.) substance and that of which it is the form, or essence, are distinct; the one is the soul, or body; the other, the soul, or body. Aristotle thought of it as a soul and a body, e.g. of the form of white, without the matter of a body, white stone. He thought that in all substance is a principle to apprehend an intellect and then a soul, and that, when we rise from sense by induction, the productive causes the passive intellect to receive the universal form or essence, e.g. of all white things; and he thought that this productive intellect is actually present in the material (i.e.) substance, which is the mind, and that the simple operations have, intellect that has not, a bodily organ; and hence he became responsible for the fancy that there is a break in bodily substance, or being, between sense and will, while intellect is working out a purely immaterial operation of the soul, results from its former and tending to the latter. It is evident that a philosophy containing so many questionable opinions is not fit to be made into an authoritative orthodoxy in metaphysics.

Now these, on the whole, are the very opinions of Aquinas, except so far as they were clearly inconsistent with the Christian faith. Aquinas thought, as an article of faith, that the world began, and that God is its Creator. This involved a change of detail in the theory of essences and of universals generally. Aquinas thought that before the creation of the one eternal essence of any kind was an abstract, intellectual, or concept of God, and that, in the mind of a builder, ante rem; that after the creation of any kind it is in re, as Aristotle supposed; and that, as we men think of it, it is post rem, as Aristotle also supposed. Of this view the part of Aristotle which家 the 'separate forms' was due to the Neoplatonists, who interpreted the "separate forms" of Plato to be ideas in intellect, and handed down their interpretation to St Augustine, and the medieval Realists like Aquinas, who then combined Neoplatonism and Platonism. The Thomist opposition to Aquinas was to essence much more than Aristotle did. Lastly, as a Christian, he supposed the whole soul to be immortal, and to form part of a new body after death. But with these modifications he accepted the general principles of Aristotle, the metaphysical dualism of matter and form, and the psychology founded upon it. The Thomism, therefore, of our day is wrong, from a metaphysical point of view, but is a serious development of Aristotle's philosophy, as seriously modified but not fundamentally corrected by Aquinas, into an authoritative orthodoxy in metaphysics.

Centuries elapsed after Aquinas before Galileo and his successors reformed natural science, and before Bacon destroyed the metaphysical dualism of matter and form by showing that a form in Nature is only a law of the action of matter, and that, as the action of a body is as individual as the body, the form is eternal only in thought (rationes). The psychology of Aristotle and Aquinas thus became impossible; for, if the form of a body is only a mode of matter, to call one's soul the form of one's body is to reduce it to only a mode of matter, and fall into materialism. Hence Descartes began the reform of psychology not only by the appeal to consciousness, "I think," but also by opposing body and soul, no longer as matter and form, but as different substances. These great improvements, due to the genius of Galileo, Bacon, and Descartes, are the fresh beginnings of modern thought, from which we dare not turn back without falling into obscurantism. What, then, is the future of metaphysics? We must return not to the authority but to the study of Aristotle. The independence of metaphysics as the science of being, the principles of contradiction and excluded middle with their qualifications, the distinction without separation between substance and attributes, the definition of substance as a distinct individual thing, the discovery that the world consists of substances existing apart but related to one another, the distinction between phenomena and noumena, the distinction between matter and form, the recognition both of the natural and of the supernatural—all these and many other half-forgotten truths are the reasons why we must always begin with the study of Aristotle's Metaphysics. But their incompleteness shows that we must go forward from Aristotle to Bacon and modern science, and even pass through the anarchy of modern metaphysics, in the hope that in the future we may discover as complete an answer as possible to these two questions:

1. What is the world of things we know?
2. How do we know it?

For authorities see the works quoted above, and the references in the articles on philosophers and philosophical subjects. (T. Ca.)
METAPONTUM—METASOMATISM

METAPONTUM (Gr. Μεταπόντιον, mod. Metaponto), an ancient city of Magna Graecia situated on the Gulf of Taranto, near the mouth of the river Bradanus, and distant about 24 m. from Tarantum and 14 m. from Heraclea. It was founded by an Achaean colony from Sybaris and Crotona about 700 B.C. Metapontum was one of the cities that played a conspicuous part in the troubles arising from the introduction of the Pythagorians into Magna Graecia, and it was there that Pythagoras died in 497 B.C. His tomb was still shown in the time of Cicero.

At the time of the Athenian expedition to Sicily (415 B.C.) Metapontum appears to have been an opulent and powerful city, whose alliance was courted by the Athenians; but it contented itself with a very trifling support. In 332 B.C., at the time of the expedition of Alexander, king of Epirus, into Italy, it was one of the first cities to enter into an alliance with him. The Second Punic War gave a fatal blow to its prosperity. After the battle of Cannae in 216 B.C. it was among the first cities in the south of Italy to declare in favour of Hannibal, and became for some years the headquarters of Hannibal. Hence, when the Scourge Hasdrubal arrived at Metapontum, he compelled him to abandon this part of Italy, the inhabitants of Metapontum abandoned their city, and followed him in his retreat.

From this time Metapontum sank; though it was still existing in the days of Cicero, Pausanias tells us that in his time nothing remained of it but a theatre and the circuit of the walls.

Metapontum has the remains of two temples, both of which seem to belong to the period 510-380 B.C. (Koldewey and Puchstein, Die griechischen Tempel in Unteritalien und Sicilien, Berlin, 1859, pp. 35-41). The so-called Chiesa di Sansone, which lay within the ancient town, and was probably dedicated to Apollo Lykus, was a peripteros measuring 186 by 91 1/2 ft., of which only the foundations are left. The capitals were 33 ft. in diameter. The temple was decorated with finely painted terra-cottas. Of the other temple, the so-called Tavole Palatine, which lay outside the area of the ancient city, and was a peripteros with 6 columns, 31 ft. in diameter, in front and 12 ft. at the sides, 15 columns are standing, with the lower portion of the epistyle. It measured 105 ft. by 49 ft. without the steps. There are also traces of the town walls, which have served for the construction of farmhouses, of tombs, and of a harbour by the shore. Pliny speaks of a temple of Juno at Metapontum supported by columns of vinewood (Hist. nat. xiv. 9). An archaic treasure-house dedicated at Olympia by the people of Metapontum has been discovered there. The railway station is the junction of the line from Battipaglia (and Naples) with that from Taranto to Reggio. (T. As.)

See M. Lacava, Topografia e storia di Metaponto (Naples, 1891).

METASOMATISM (Gr. μετασοματίζω, change, σώμα, body), in petrology, a process of alteration of rocks by which their chemical composition is modified, new substances being introduced while those originally present are partly or wholly removed in solution. For example a limestone may be converted into a siliceous chert, a dolomite, an ironstone, or a mass of metalliferous ores by metasomatic alteration. The process is usually incomplete, greater or smaller portions of the original rock remaining. The agencies of metasomatism are in nearly all cases aqueous solutions; probably they were often at a high temperature, as metasomatic changes are especially liable to occur in the vicinity of igneous intrusions (laccoliths, dikes and necks) where large quantities of water were given off by the volcanic magma at a time when it had solidified but was not yet cold. Metasomatism also usually goes on at some depth, so that we may readily believe that it is favoured by increase of pressure. On the other hand, there are many instances in which these processes cannot be shown to have taken place at temperatures or pressures above those which normally exist in the upper part of the earth’s crust (e.g. dolomitization and silification of limestones). There are also cases of metasomatism in which steam and vapours have undoubtedly been operative; the temperatures were probably above the critical temperature of water. Changes of this sort are described as pneumatolytic, being induced by gases (see PNEUMATOLOGY).

By metasomatism new minerals replace the primitive ones; at the same time the original rock-structures may be completely obliterated. An igneous rock for example may be entirely replaced by crystalline massive quartz, a fossiliferous limestone by granular crystalline dolomite. It is equally common, however, to find that the structure of the original rock is preserved though its substance has been entirely altered. An example of this is the pseudomorphs of the ancient limestone rock of the Chalk, which is frequently found as veins or parts of veins (see PETROLOGY, Pl. IV. fig. 5) and casts of the fossils which the limestone contained may be formed of siderite or of chalcedony. In this case the rock resembles a pseudomorph, which is the term applied to a mineral which has been entirely replaced by another mineral without losing its original crystalline form. As a result of metasomatism rocks usually become more crystalline, especially those which have been in large part built up of fossil organic remains; this is a consequence of the new substances having been deposited by purely inorganic processes from solution in water.

The chemical change is often complete, as when a limestone is replaced by chert or otherwise silificated, but it is probably more usually incomplete, part of the substance of the original rock having been retained though possibly in new mineral combinations. When a limestone is replaced by ironstone (e.g. carbonate of iron or siderite) part of at least the carbonic acid may be that of the limestone. A dolomite, formed from a limestone, contains more than one-half of its weight of carbonate of lime presumably derived from the limestone itself; yet in this case the mineral transformation may be perfect, as the dolomite retains none of the calcite of which the limestone was formed; it is all present as the double carbonate of lime and magnesia (or dolomite). When a granite is converted by emanations containing fluorine and boron into a quartz-tourmaline rock (schorr rock, q.v.) or a quartz mica rock (greisen, q.v.) it can be proved by analysis that there has been very little modification of the chemical composition of the original mass. This resembles paramorphism in minerals, in which one mineral is substituted for another having the same chemical composition (e.g. kyanite for andalusite).

The relations between metamorphism and metasomatism are very close; in fact some authors regard metasomatism as a variety of metamorphism. It is generally true, however, that in true metamorphic changes there is little chemical alteration; sandstones pass into quartzites, clays into mica-schists and gneisses, limestones into dolomites; but without and through the mediation of iron, for the original minerals are being substituted and new structures being produced at the same time. In metasomatism, on the other hand, chemical alteration is supposed to be most advanced, and only a few minerals appear, but the original structures are sometimes retained.

The facility with which a rock undergoes metasomatism depends partly on its nature, and partly on the circumstances in which it is found. Limestones, being readily soluble under natural conditions, are especially liable. The Cleveland iron ores of Yorkshire are limestones replaced by siderite and limonite; the Whitehaven iron ores, are metasomatic replacements of limestone by haematite. The former are of Mesozoic, the latter of Palaeozoic age, but both have been changed in very much the same way by percolating solutions containing salts of iron. In some limestones and dolomites the presence of iron is general. In other cases, however, there may be almost no iron present very irregularly, along bedding planes, faults and fractures. An ironstone may in many places be traced laterally into a limestone, the amount of iron in the rock gradually diminishing. Some iron-stones (Carboniferous, Jurassic, &c.) retain the oolith structures of the original limestone; others show corals, shells and other calcareous fossils replaced by iron ores. When beds of shale or sandstone are impregnated with solutions saturated with iron oxides, a fact which indicates that the ready solubility of the calcareous rocks was a dominating factor in determining the metasomatic deposits. It is believed that the Whitehaven iron ores may be derived from the ironstones of the Coal-Measures which once covered the limestone districts.

Dolomitization of limestones is even more common than replacement of iron ores. That it is going on at the present day is evident from the fact not only that many veins, but entire masses have shown that these may be extensively dolomitized in their deeper parts, and the older limestones such as the Triassic of the Alps, the Carboniferous Limestone of England and the Cambrian
Limestone of Scotland are sometimes converted into dolomite over wide areas. There has been an introduction of magnesia, with some dolomite, where it crystallizes in the formation of small rhombohedra of dolomite; it frequently becomes porous and full of drusy cavities, owing to the contraction in volume which takes place, and the fossils and other organic remains left in the rock disintegrate and are carried away; the changes pass outwards from fissures and bedding planes and spreads gradually through the mass of the limestone; often the transformation is complete, and the dolomite is rich in the original rock, in which replace the original limestone by chaledony, chert or quartz, is often exhibited on a large scale. The formation of flint nodules and chert bands is of this nature; the silica is not really an introduction from without, for that is merely the material of the line-siliceous skeletons of sponges, radiolaria and other organisms, which at first were widely scattered through the limestone and at a later time were dissolved by percolating waters, percolated through the rock and were subsequently lignified; in the original nodules are masses of cryptocrystalline silica. In limestones extensive deposits of zinc ore may occur, usually calamine. These are important sources of the metal and then litigated for doubt that they have formed by a process of metasomatic replacement, e.g. Carthagena, Rail (in Carinthia) and Belgium. In many parts of western North America (Nevada, Arizona, &c.) great deposits of copper, lead and silver ores are worked in crystalline limestones. They are often highly silicified, and associated with them are intrusive igneous rocks such as granite, dacite, porphyry and diabase. The ores occur not only in veins andshoots, but in large masses replace the limestones and, in geologists who have examined these mining districts are nearly unanimous as to the metasomatic nature of a large part of these deposits. Other rocks such as rill, volcanic breccia, shale, porphyry and anorthosite in andesite, rhyolite and diorite, with greater or less abundance, are often in the largest ore bodies are found in the limestones. Secondary enrichment has often taken place on a considerable scale. The constant presence of igneous rocks indicates that they are coeval with the introduction of the metals, and the deposits are often of such a kind as to show that post-volcanic discharges of magmatic gases and water have been the actual mineralizing agents. Bisbee, Cato, in the Gila district in Arizona, Magdalena staff in Utah, and the Eureka district in Nevada are good examples of the deposits in question.

As indicated above, sands, sandstones and igneous rocks may be silicified, to some extent, under suitable conditions. Rhyolites and rhyolitic tuffs are often impregnated with silica to such an extent that they become almost massive quartz, and the fluidal, porphyritic, spheroidal and other igneous structures of the original rock may be re-defined into a siliceous pseudomorph. There are many examples of this in North Wales and the Pentland Hills. In andesites, serpentines and trachyte silification is frequently found in circumstances indicating that the changes are not due to weathering but are the effect of post-volcanic emanations of heated waters. Silicified shales may accompany mineral deposits, e.g. in the Cornish tin mines the Killas or grey slate may be converted into quartz and brown tuff. In the rich lode of the Great Western copper mines of Parys Mountain, Anglesey, formerly of great importance as producers of this metal, there are large areas of siliceous shales, and the impure porphyry and gabbro, the emerald; chlorite and epidote are frequently present in silicified igneous rocks. As a further instance of mineral deposition in metasomatized igneous rocks we may quote the Cripple Creek gold-field, Colorado, where veins, lenses, boudins, and dike-like intrusions have been filled with pyrite, dolomite, fluorite, calcavere and other new minerals together with quartz.

Another type of metasomatic alteration is phosphatization. This is most common in limestones, and many of the most important bedded phosphate deposits are of this origin. Trachytes and other igneous rocks are occasionally phosphatized. The source of the phosphate is for the most part the skeletons of animals, vertebrates and bones, teeth, shells of certain brachiopods, trilobites and other organisms. Guano, the excreta of birds, is rich in phosphates and these are washed downwards by rain producing metasomatized alteration of the phosphatized porcelain and the phosphatic remains are obtained in great quantities in Christmas Island, Sombrero, Curacao and other uninhabited limestone islands. (J. S. F.)

METASTASIO (1658-1738). Pietro Trapassi, the Italian poet who is better known by his assumed name of Metastasio, was born in Rome on the 13th of January 1658. His father, Felice Trapassi, a native of Assisi, came to Rome and took service in the Corsican regiment of the papal forces. He subsequently married a Bolognese woman, called Francesca Galasti, and established himself in business as a grocer in the Via dei Cappellari. Two sons and two daughters were the fruit of this marriage. The eldest son, Leopoldo, must be mentioned, since his name is devoured and played with by the tribunal of history, while quite a child, often held a crowd attentive in the streets while he recited impromptu verses on a given subject. It so happened that, while he was thus engaged one evening in the year 1709, two men of distinction in Roman society stopped to listen to his declamation. These were Gian Vincenzo Gravina, famous for legal and literary erudition, famous no less for his dictatorship of the Arcadian Academy, and Lorenzini, a critic of some note. Gravina was at once attracted by the boy's poetical talent and charm of person, interested himself in the genius he had accidentally discovered in him, introduced him to his protege, beat in the course of a few weeks adopted him. Felice Trapassi was glad enough to give his son the chance of a good education and introduction into the world under auspices so favourable. Gravina helened the boy's name Trapassi into Metastasio; and intended his adopted son to be a jurist like himself. He therefore made the boy learn Latin and begin the study of law. At the same time he cultivated his literary gifts, and displayed the youthful prodigy both at his own house and in the Roman coteries. Metastasio soon found himself competing with the most celebrated improvisor of his time in Italy. Days spent in severe studies, evenings devoted to the task of improvising eighty stanzas at a single session, were fast ruining Pietro's health and overstraining his poetic faculty. At this juncture Gravina had to journey into Calabria on business. He took Metastasio with him, exhibited him in the literary circles of Naples, and then placed him under the care of his kinsman Gregorio Caroprese at a little place called Scala. In country air and the quiet of the southern seashore Metastasio's health revived. It was decreed by Gravina that he should never again, but should live a life surrounded for noble efforts, when, having completed his education, he might enter into competition with the greatest poets.

Metastasio responded to his patron's wishes. At the age of twelve he translated the Hiod into octave stanzas; and two years later he composed a tragedy in the manner of Seneca upon a subject chosen from Trissino's Italia liberata — Gravina's favourite epic. It was called Giustina. Gravina had it printed in 1713; but the play is illibes; and forty-two years afterwards we find Metastasio writing to his publisher, Calsabigi, that he would willingly suppress it. Caroprese died in 1714, leaving Gravina his heir; and in 1718 Gravina also died. Metastasio inherited house, plate, furniture and money, which amounted to 15,000 scudi, or about £4000. At a meeting of the Arcadian Academy, he recited an elegy on his patron, and then settled down, not it seems without real sorrow for his loss, to enjoy what was no inconsiderable fortune at that period. Metastasio was now twenty. During the last four years he had worn the costume of abbé, having taken the minor orders without which it was then useless to expect advancement in Rome. His romantic history, personal beauty, charming manners and charming talents made him much sought after, and when at his twenty-sixth years were out he had spent his money and increased his reputation for wit will surprise no one. He now very sensibly determined to quit a mode of life for which he was not born, and to apply himself seriously to the work of his profession. Accordingly he went to Naples, and entered the office of an eminent lawyer named Castagnola. It would appear that he addressed himself as clerk, for Castagnola exercised severe control over his time and energies. While slaving at the law, Metastasio in 1721 composed an epitalamium, and probably also his first work, Enrico, Elector of Bavaria, in which he showed that the spirit of his patroness the Princess Pinelli di Sangro to the Marchese Belmonte Pigafattel. But the event which fixed his destiny was the following. In 1722 the birthday of the empress had to be celebrated with more than ordinary honours, and the vicerey applied to Metastasio to compose a serenade for the occasion. He accepted this invitation, but it was arranged that his authorship should be kept secret. Under these conditions Metastasio produced Gli orf orteri. Set to music by Porpora, it won the most extraordinary applause. The great Roman prima donna, Marianna Bulgarlesi, called La Romanina from her birthplace, again played the part of Venus in this drama, harbored no pains until she had discovered its author. La Romanina forthwith took possession of him, induced him to quit his
lawyer's office, and promised to secure for him fame and independence, if he would devote his talents to the musical drama. In La Romanina's house Metastasio became acquainted with the greatest composers of the day—Pomponio, from whose he took lessons in music; with Hasse, Pergolesi, Scarlatti, Vinci, Leo, Durante, Marcello, all of whom were destined in the future to set his plays to melody. Here too he studied the art of singing, and learned to appreciate the style of such men as Farinelli. Gifted himself with extraordinary facility in composition, and with a true poetical feeling, he found no difficulty in producing plays which, while beautiful in themselves, judged merely as works of literary art, became masterpieces as soon as their words were set to music, and rendered by the singers of the greatest school of vocal art the world has ever seen. Reading Metastasio in the study, it is impossible to do him justice. But the conventionality of all his plots, the absurdities of many of his situations, the violence he does to history in the persons of some leading characters, his "damnable iteration" of the theme of love in all its phases, are explained and justified by music.

Metastasio resided with La Romanina and her husband in Rome. The generous woman, moved by an affection half maternal half romantic, and by a true artist's admiration for so rare a talent, adopted him more passionately even than Gravina had done. She took the whole Trapassi family, father, mother, brother, sisters—into her own house. She fostered the poet's genius and pampered his caprices. Under her influence he wrote in rapid succession the Didone abbandonata, Catone in Utica, Ezio, Alessandro nell'Indie, Semiramide riconosciuta, Siroe and Artaserse. These dramas were set to music by the chief composers of the day, and performed in the chief towns of Italy. But meanwhile La Romanina was growing older; she had ceased to sing in public; and the poet felt himself more and more dependent in an irksome sense upon her kindness. He gained 300 scudi (about £60) for each opera; this pay, though good, was precarious, and his means of living limited. In September 1729 he received the offer of the post of court poet to the theatre at Vienna, with a stipend of 3000 florins. This he at once accepted. La Romanina unselfishly sped him on his way to glory. She took the charge of his family in Rome, and he set off for Austria.

In the early summer of 1730 Metastasio settled at Vienna in the house of a Spanish Neapolitan, Nicolò Martinez, where he resided until his death. This date marks a new period in his artistic activity. Between the years 1730 and 1740 his finest dramas, Adrano, Demetrio, Istriile, Demofante, Olimpide, Clamenzi di Tito, Achille in Sciro, Temistocle and Attilio Regolo, were produced for the imperial theatre. Some of them had to be composed for special occasions, with almost incredible rapidity—the Achille in eighteen days, the Permessia in nine. Poet, composer, musical copyist and singer did their work together in frantic haste. Metastasio understood the technique of his peculiar art in its minutest details. The experience gained at Naples and Rome, quickened by the excitement of his new career at Vienna, enabled him almost instinctively, and as it were by inspiration, to hit the exact mark aimed at in the opera.

At Vienna Metastasio met with no marked social success. His plebeian birth excluded him from aristocratic circles. But, to make up in some measure for this comparative failure, he enjoyed the intimacy of a great lady, the Countess Althann, sister-in-law of his old patroness the Princess Belmondo Pignatelli. She had lost her husband, and had some while occupied the post of chief favourite to the emperor. Metastasio's liaison with her became so close that it was even believed they had been married. But the even tone of his existence was broken in the year 1734 by the one dark and tragic incident of his biography. It appears that La Romanina had at last got tired of his absence. Could not Metastasio get her an engagement at the court theatre? The poet at this juncture revealed his own essential feeblessness of character. To La Romanina he owed almost everything as a man and as an artist. But he was ashamed of her and tired of her. He vowed she should not come to Vienna, and wrote dissuading her from the projected visit.

The tone of his letters alarmed and irritated her. It is probable that she set out from Rome, but died suddenly upon the road. All we know is that she left him her fortune after her husband's life interest in it had expired, and that he was overwhelmed with grief and remorse, immediately renounced the legacy.

This disinterested act plunged the Bulgarelli-Metastasio household at Rome into confusion. La Romanina's widower married again. Leopoldo Trapassi, and his father and sister, were thrown upon their own resources.

As time advanced the life which Metastasio led at Vienna, together with the climate, told upon his health and spirits. From about the year 1745 onward he wrote but little, though the cantatas which belong to this period, and the canzonet Ecco quel fero e triste anata, which he sent to his friend Farinelli, rank among the most popular of his productions. It was clear, as Vermorel has phrased it, "what ailed him was mental and moral ennui." In 1755 the Countess Althann died, and Metastasio was more than ever reduced to the society which gathered round him in the bourgeois house of the Martinez. He sank rapidly into the habits of old age; and, though his life was prolonged till the year 1782, very little can be said about it. On the 15th of April he died, bequeathing his whole fortune of some 150,000 florins to the five children of his friend Martinez. He had survived by five of his relatives.

During the long period of twenty years in which Metastasio overlived his originality and creative powers his fame went on increasing. In his library he counted as many as forty editions of his own works. They had been translated into French, English, German, Spanish, even into modern Greek. They had been set to music over and over again by every composer of distinction, each opera receiving this honour in turn from several of the most illustrious men of Europe. They had been sung by the best virtuosi in every capital, and there was not a literary academy of note which had not conferred on him the honour of its presidency. But his position as a fixed point of distinction inside the regular class of singers to whom Farinelli belonged, Metastasio's music suffered eclipse. It was indeed a just symbolic instinct which made the poet dub this unique soprano his twin-brother.

The musical drama for which Metastasio composed, and in working for which his genius found its proper sphere, has so wholly passed away that it is now difficult to assign his true place to the poet in Italian literary history. His inspiration was essentially emotional and lyrical. The chief dramatic situations are expressed by lyrics for two or three voices, embodying the several contending passions of the agents brought into conflict by the circumstances of the plot. The total result is not pure literature, but literature supremely fit for musical effect. Language in Metastasio's hands is exquisitely pure and limpid. Of the Italian poets, he possessed a special admiration for Tasso and for Marini. But he avoided the conceits of the latter, and was no master over the refined richness of the former's diction. His own style reveals the improvisatore's facility. Of the Latin poets he studied Ovid with the greatest pleasure, and from this predilection some of his own literary qualities may be derived. For sweetness of versification, for limpidity of diction, for delicacy of sentiment, for romantic situations exquisitely rendered in the simplest style, and for a certain delicate beauty of imagery sometimes soaring to ideal sublimity, he deserves to be appreciated so long as the Italian language lasts.

There are numerous editions of Metastasio's works. That by Calzabigi (Paris, 1755, 9 vols. 8vo) published under his own superintendence, was the poet's favourite. Another of Turin (1752) and a
third of Paris (1780) deserve mention. The posthumous works were printed at Vienna, 1795. The collected editions of Genoa (1802) and Padua (1811) will probably be found most useful by the general student. An edition of the letters, by Carchedi, was published at Bologna at the soil and other circumstances which held by Aligi (Assisi, 1783); by Charles Burney (London, 1760); and by others; but by far the most vivid sketch of his biography will be found in Vernon Lee's Studies of the 18th Century in Italy (London, 1880) a work which provides the light upon the development of Italian dramatic music, and upon the position occupied by Metastasio in the artistic movement of the last century. (J. A. S.)

METAURUS—METCALFE

Third, is the old country of the Metasii, and is more frequent in inscriptions of the imperial period, a river of Italy, which flows into the sea a little south-east of Funan Fortunae (mod. Fano). On its banks Hazdrubal, while marching to the aid of Hannibal, in 207 B.C., was defeated and slain by the Roman army, this being the decisive battle of the Second Punic War. The exact site of the battle is uncertain; tradition places it between Fossombrone and the Furlo Pass, but it is probable that it occurred near the sea-coast.

METAXAS, ANDREAS (1786-1860), Greek politician, was born in the island of Cephalonia. During the latter part of the War of Independence (1824-1827) he accompanied Capo d'Istria to Greece, and was appointed by him minister of war. When Capo d'Istria was murdered in 1831 Metaxas became a member of the Imperial Council, and was made joint minister of the Interior and War, and the latter of King Otho in 1833. During the minority of Otho he was named privy councillor and minister at Madrid and Lisbon. In 1840 he was recalled and appointed minister of war. In 1843-1844 he was president of the council of ministers, and he subsequently held the post of ambassador at Constantinople from 1850 to 1854. He died at Athens on the 10th of September 1860.

MÉTAYAGE SYSTEM, the cultivation of land for a proprietor by one who receives a proportion of the produce. The system has never existed in England and has no English name, but in certain districts of France on the 39th parallel north it is usual, and is still very common. It is also not unusual in Portugal, Greece, and in the countries bordering on the Danube. In Italy and France, respectively, it is called mezzorio and métayage, or halving—the halving, that is, of the produce of the soil between landowner and landholder. These expressions are not, however, to be understood in a more precise sense than that in which we sometimes talk of a larger and a smaller half. They merely signify that the produce is divisible in certain definite proportions, which must obviously vary with the varying fertility of the soil and the other circumstances which hold and which in practice vary so much that the landlord's share is sometimes as much as two-thirds, sometimes as little as one-third. Sometimes the landlord supplies all the stock, sometimes only part—the cattle and seed perhaps, while the farmer provides the implements; or perhaps only half the seed and half the cattle, the farmer finding the other halves—taxes too being paid wholly by one or the other, or jointly by both.

English writers were unanimous, until J. S. Mill adopted a different tone, in condemning the métayage system. They judged it by its appearance in France, where it has never worn a good name. Under the ancien régime not only were all direct taxes paid by the métayer, the noble landowner being exempt, but these taxes, being assessed according to the visible produce of the soil, operated as penalties upon all endeavours to augment its productiveness. No wonder, then, if the métayer fancied that his interest lay less in exerting himself to augment the total to be divided between himself and his landlord, than in studying how to defraud the latter part of his rightful share; nor if he has not yet got rid of habits so acquired, especially when it is considered that he still is destitute of the fixity of tenure without which métayage cannot prosper. French métayers, in Arthur Young's time, were "removable at pleasure, and obliged to conform in all things to the will of their landlords," and so in general they are still. Yet even in France, although métayage and extreme rural poverty usually coincide, there are provinces where the contrary is the fact, as it is also in Italy. Indeed, to every tourist who has passed through the plains of Lombardy with his eyes open, the knowledge that métayage has for ages been there the prevailing form of tenure ought to suffice for the triumphant vindication of métayage in the ab- abs. An explanation of the contrasts presented by métayage in different regions is not possible. The development of the metayer 1833. In any case worthy of commendation, must be a genuine partnership, one in which there is no sleeping partner, but in the affairs of which the landlord, as well as the tenant, takes an active part. Wherever this applies, the results of métayage appear to be as eminently satisfactory, as they are decidedly the reverse wherever the landlord holds himself aloof.

In France there is also a system termed métayage par groupes, which consists in letting a considerable farm, not to one métayer, but to an association of several, who work together for the general good, under the supervision, either of the landlord himself, or of his bailiff. This arrangement gets over the difficulty of finding tenants possessed of capital enough for any but very small farms.

See further the section Agriculture in the articles France, Greece, Italy, &c., and consult J. Cruvelier, Étude sur le métayage (Paris, 1864).

Metcalf, Willard Leroy (1850- ), American artist, was born at Lowell, Massachusetts, on the 1st of July 1838. He was a student of Thomas Theophilus Metcalfe, then a major in the Bengal army, who afterwards became a director of the East India Company, and was created a baronet in 1892. Having been educated at Eton, he in 1880 sailed for India as a writer in the service of the Company. After studying Oriental languages as the first student at Lord Wellesley's College of Fort William, he, at the age of nineteen, was appointed political assistant to General Lake, who was then conducting the final campaign of the Mahatta war against Holkar. In 1860 he was selected for the responsible post of envoy to the court of Ranjit Singh at Lahore; here, on the 25th of April 1860, he concluded the important treaty securing the independence of the Sikh states between the Sutlej and the Jumna. Four years afterwards he was made resident at Delhi, and in 1819 he received from Lord Hastings the appointment of secretary in the secret and political department. From 1820 to 1825 Sir Charles (who succeeded his brother in the baronetcy in 1822) was resident at the court of the nizam, and afterwards was summoned in an emergency to his former post at Delhi. In 1827 he obtained a seat in the supreme council, and in March 1835, after he had been the first governor of the proposed new presidency of Agra, he provisionally succeeded Lord William Bentinck in the governor-generalship. During his brief tenure of office (it lasted only for one year) he carried out several important measures, including that for the liberation of the press, which, while almost universally popular, complicated his relations with the directors at home to such an extent that he resigned the service of the Company in 1838. In the following year he was appointed by the Melbourne administration to the governorship of Jamaica, where the difficulties created by the recent passing of the Negro Emancipation Act had called for a high degree of tact and ability. Sir Charles Metcalfe's success in this delicate position was very marked, but unfortunately his health compelled his resignation and return to England in 1842. Six months afterwards he was appointed by the Peel ministry to the governor-generalship of Canada, and his success in carrying out the policy of the home government was rewarded with a
MetteLus, the name of a distinguished family of the Caecilian (plebeian) gens in ancient Rome. The following are the most important:—

1. Lucius Caecilius Metellus, general during the first Punic War. Consul in 251 B.C., he was sent to Sicily, and gained a decisive victory over Hasdrubal, who, trusting to his numerically superior forces and the alarm inspired by his elephants, ventured to attack him. Metellus's victory was in great measure due to a panic caused amongst the elephants by his clever manœuvring. A number of these animals were sent in specially constructed rafts to adorn his triumph, and from this time the elephant frequently occurs as a device on the coins of the Metelli. In 242, when the temple of Vesta was destroyed by fire, Metellus succeeded in bringing out the Palladium uninjured, but lost his eyesight. As a reward, he was granted permission to ride to the senate-house in a carriage, a privilege hitherto unheard of. But the story of his blindness is doubtful, since it is hardly consistent with his appointment as dictator in 224 "for the purpose of holding the comitia," nor is any mention made of it by the extract [Pliny, Nat. Hist. vi. 43 (45)] from the funeral oration pronounced over him by his son.

2. Quintus Caecilius Metellus, son of (1), became consul in 206 as a reward for his services at the Metaurus. In 205 B.C. he was dictator for holding the comitia; in 201 one of the commissioners for dividing the public land in Samnium and Apulia amongst the Roman veterans; in 186 he conducted an embassy to Macedonia, afterwards proceeding to Peloponnesus to investigate the quarrel between Sparta and the Achaenae. He is the Metellus who caused the poet Naevius (q.v.) to be imprisoned and exiled for having attacked him on the stage.

3. Lucius Caecilius Metellus, possibly son of (1), when the disastrous news of the battle of Cannae (216) reached Rome, proposed to a number of young nobles that they should leave Italy and offer their services to some foreign ruler, but they were prevented by the threats of the younger Scipio from carrying out their purpose. For this offence, when quaestor two years later, he was degraded by the censors from his tribe to the class of aerarii. Nevertheless, he was elected one of the tribunes for the following year, but his attempt to call the censors to account for their action proved unsuccessful in the face of the opposition of his colleagues.

4. Quintus Caecilius Metellus Macedonicus (d. 115 B.C.), praetor 148 B.C., defeated the usurper Andronicus (q.v.) in Macedonia and forced him to surrender. Under his superintendence the country was made a Roman province. In 146, he attacked the Achaenae to avenge an insult offered to a Roman embassy at Corinth. He gained decided successes over them at Scarpheia and Chaeronea, but was superseded by L. Mummius. On his return to Italy he received the honour of a triumph and the title of Macedonicus. Consul in 143, he reduced the Cilicians in northern Spain to obedience. In 131, when censor with Q. Pompeius (they were the first two plebeian censors), he proposed that all citizens should be compelled to marry. He expelled a number of senators, one of whom, the tribune C. Atinius Labeo, proposed that he should be hured from the Tarpeian rock; his life was only saved through the intervention of another tribune. He was an opponent of the Gracchi, although not averse from moderate reform. He was a strict disciplinarian, a good general, and a type of the ancient Roman both in public and private life. He erected a splendid colonnade in the Campus Martius, and two temples dedicated to Jupiter Stator and Juno.

5. Quintus Caecilius Metellus Numidicus, consul 109, and commander in the Jugurthine War. He defeated Jugurtha (q.v.) by the river Muthul, and after a difficult march through the desert took his stronghold, Thala. Marius, however, who had been intriguing for the command, accused Metellus of protracing the war, and received the consulsiphip for 107 with the province of Numidia. Metellus received a splendid triumph and the title of Numidicus. Saturninus, whom as a censor he tried to remove from the senate, passed in 105 an agrarian law, inserting a provision that all senators should swear to it within five days. All complied but Metellus, who retired to Asia. After Saturninus was killed he returned, and died (probably in 97). He was a man of the highest integrity, a strict and efficient general, and one of the chief leaders of the aristocratic party. He was a man of education and learning, and Cicero speaks highly of him as an orator.

6. Quintus Caecilius Metellus Pius, so called from his efforts to bring about the recall of his father Numidicus from exile. He was one of the commanders in the Social War, and defeated Q. Pompeius Silo, the Marian leader in Gaul, on his departure for Asia, gave him proconsular command over south Italy. When Marius returned to Italy and joined Cinna, the soldiers, who had no confidence in the consul Gaenas Octavius, wished Metellus to take command, but he refused. The soldiers deserted in large numbers, and considering it impossible to defend Rome, Metellus retired to Africa and afterwards to Liguria, resuming his former proconsular command on Sulla's return. In the war against Marius he gained several important successes, and after his victory over C. Norbanus at Favenia (82) he was sent to Romanize Spain, and afterwards, with Sulla, he went to Spain next year against Sertorius, who pressed him hard till the arrival of Pompey in 76. Next year Metellus defeated Sertorius's lieutenant Hirtuleius at Italica and Segovia, and joining Pompey rescued him from the consequences of a check at Sucro. From this time Sertorius grew weaker till his murder in 72. In 71 Metellus returned to Rome and triumphed. He became pontifex maximus, and died probably at the end of 64. He was an upright man of moderate ability.

7. Quintus Caecilius Metellus Celer, legate of Pompey in his 65 B.C., resisted the offer of his power by his wife Claudia, and at the battle of Actium delivered the signal check to the flight of Catiline to the north by blocking the passes, and in 62 went into the province of Cisalpine Gaul with the title of proconsul, although he did not become consul till 60. A strong supporter of the optimates and an enemy of Pompey, he strenuously opposed the agrarian law brought forward by the tribune Lucius Flavius, to provide for Pompey's veterans, and stood firm even though imprisoned; the law had to be given up. He also tried, though fruitlessly, to obstruct Caesar's agrarian law in 59. He died suddenly in the same year—it was usually supposed from poison administered by his wife Claudia. He was praetor in 51 B.C., proconsul of Africa in 49 B.C., and praetor in 39 B.C., and afterwards had a distinguished career in the government of the East.

8. Quintus Caecilius Metellus Nepos, son of a Metellus of the same name, so called because he was the grandson of (4). He was legate to Pompey in the war against the Mediterranean pirates (67), and took part in the Syrian campaign. In 63 he returned to Rome, to assist Pompey in carrying out his plans. He violently attacked Cicero, and refused to allow him to deliver the customary speech on laying down office as consul; he even threatened to impeach him for having executed Roman citizens (referring to the Catilinarian conspirators) without a trial. In 62 his proposal that Pompey should be summoned to Italy to restore order was bitterly opposed by Cato, and on the day set down for the bill a fight took place in the forum. Metellus fled to Pompey, but soon returned with him to Rome. In 60, when praetor, he proposed a law for the abolition of the vestalizia in Italy. In 57 he was consul, but offered no opposition to the return of Cicero from exile. In 56 he was governor of Hither Spain, where he was engaged in hostilities against the Vescani with indifferent success. He appears to have died in Rome in the following year. He was a mere creature of Pompey.

9. Quintus Caecilius Metellus Pius Scipio, son of P. Scipio Nasica, was adopted by (6). He was accused of bribery in 60 B.C., and defended by Cicero, to whom he had rendered valuable assistance during the Catilinarian conspiracy. In August 52, he became consul through the influence of Pompey, who had married his daughter Cornelia. In 49 he proposed that Caesar should disband his army within a definite time, under pain of being declared an enemy of the state. After the outbreak of the civil war, the province of Syria was assigned to
him, and he was about to plunder the temple of Artemis at Ephesus when he was recalled by Pompey. He commanded the centre at Thasos, and afterwards went to Africa, where by Cato's influence he received the command. In 46 he was defeated at Thapsus; while endeavouring to escape to Spain he fell into the hands of P. Sittius, and put himself to death. His connexion with two great families gave him importance, but he was selfish and licentious, wanting in personal courage, and his violence drove many from his party.

10. Quintus Caecilius Metellus, surnamed Creticus, Roman general. Consul in 69 B.C., he was appointed to the command of the war against Crete, the headquarters of the pirates of the Mediterranean. Its subjugation proceeded slowly but surely until 67, when Pompey claimed the control of affairs in virtue of the powers conferred upon him by the Gabinian law. Thereupon the Cretans, who had been treated with great harshness by Metellus, offered to surrender to Pompey, who enjoyed a reputation for leniency towards the conquered. Pompey accepted the offer and sent instructions to Metellus to suspend operations. Metellus refused and completed the conquest of the island, which was annexed to Cyrene, on the coast of some a Roman province. On Metellus's return to Rome the partisans of Pompey succeeded in keeping him out of a triumph until after the Catilinarian conspiracy, when he made his entry into the city and received the name Creticus in honour of his achievements. Metellus naturally joined the senatorial party in their opposition to Pompey, and had the satisfaction of preventing the ratification of what he had done in Asia. He was one of a commission of three sent (60) to investigate the state of affairs in Gaul, where disturbances were apprehended. He appears to have been all his life in 54, but nothing further is known of him.

On the family of the Metellis generally, see M. Wendel, De Caeciliis Metellis, i. (Bonn, 1875), for its history up to the time of the Gracchi; the new edition by F. Gröbe of Drummann's Geschichte Roms, i.; and the apocryphal history by Paul F. in Pauli F. Geschichte der Alterrelicenphöpädie der classischen Altertumswissenschaft, iii. pt. i (1897).

METEMPSYCHOSIS (Gr. μετεμψυχοσις), or Transmigration of the Soul, the doctrine that at death the soul passes into another living creature, man, animal, or even plant. This doctrine, famous in antiquity and still held as a religious tenet by certain sects of the civilized world, has its roots far back in primitive culture. It is developed out of three universal savage ideas: (1) that a soul is the personal destiny of a living being; (2) that animals and even plants have souls, and are possessed to a large extent of human powers and passions; (3) that souls can be transferred from one organism to another. Innumerable examples might be mentioned of the notion that a new-born child is the reincarnation of someone departed, as in Tibet the soul of the Dalai-Lama is supposed to pass into an infant born nine months after his decease. Transmigration of human souls into non-human bodies is implied in totemism (q.v.), for, as Professor Frazer says, "it is an article of faith that as the clan spring from the totem, so each clanman at death reassumes the totem form." All these savage notions are to be regarded as presuppositions of metempsychosis, rather than identified with that doctrine itself as a reasoned theory.

Till full investigation of Egyptian records put us in possession of the facts, it was supposed that the Egyptians believed in metempsychosis, and Herodotus (ii. 123) explicitly credits them with it. We now know that he was wrong. All that they believed was that certain privileged souls might in the other world be able to assume certain forms at pleasure, those of a swan, hawk, lion, &c. Herodotus misunderstood the Egyptians to hold beliefs identical with those which were current in his day in Greece. In India, on the contrary, the doctrine was thoroughly established from ancient times, from not the most ancient, as it is not in the Vedas; but onwards from the Upanishads. In them it is used for moral retribution: he who kills a Brahman is, after a long progress through dreadful hells, to be re-born as a dog, pig, ass, camel, &c. This we always find in metempsychosis as a reasoned theory. It is formed by combination of two sets of ideas which belong to different planes of culture: the ideas of judgment and punishment after death elaborated in a relatively civilized society by a priestly class are combined with ideas, like that of totem-transmigration, proper to a savage society. In India we may explain the whole phenomenon as an infusion of the lower beliefs of the non-Aryan conquered races into the higher religious system of their Aryan conquerors. In later Hinduism metempsychosis reached a monstrous development; according to Monier-Williams it was believed that there were 8,400,000 forms of existence through which all souls were liable to pass before returning to their so-called Deity. Buddhism appeared as a reaction against all this, and sought by a more explicit modification of the soul and the body to realize the theory with its own pessimistic view of the world. According to Buddhism there is no soul, and consequently no metempsychosis in the strict sense. Something, however, is transmitted, i.e. Karma (character), which passes from individual to individual, till in the perfectly righteous man the will to live is extinguished and that particular chain of lives is brought to an end.

We do not know exactly how the doctrine of metempsychosis arose in Greece; it cannot, as was once supposed, have been borrowed from Egypt and is not likely to have come from India. It is easiest to assume that sage ideas which had never been extinguished were utilized for religious and philosophic purposes. The Orphic religion, which held it, first appeared in Thrace upon the semi-barbarous north-eastern frontier. Orpheus, its legendary founder, is said to have taught that "soul and body are united by a compact unequally binding on either; the soul is divine, immortal and aspires to freedom, while the body holds it captive as a prisoner. Death dissolves this compact, but only to re-impress the liberated soul after a short time; for the wheel of birth revolves inexorably. Thus the soul continues its journey, alternating between a separate unrestrained existence and fresh reincarnation, round the wide circle of necessity, as the companion of many bodies of men and animals. To these unfortunate prisoners Orpheus proclaims the message of liberation, that they stand in need of the grace of redeeming gods and of Dionysus in particular, and calls them to turn to God by ascetic piety of life and self-purification: the purer their lives the higher will be their next reincarnation, until the soul has completed its round of existences, and has returned to being a pure god from whom it comes." Such was the teaching of Orphism which appeared in Greece about the 6th century B.C., organized itself into private and public mysteries at Eleusis and elsewhere, and produced a copious literature.

The earliest Greek thinker with whom metempsychosis is connected is Thracius; but Pythagoras, who is said to have been his pupil, is its first famous philosophic exponent. Pythagoras probably neither invented the doctrine nor imported it from Egypt, but made his reputation by bringing Orphic doctrine from North-Eastern Hellas to Magna Graecia and by instituting societies for its diffusion.

The real weight and importance of metempsychosis is due to its adoption by Plato. Had he not embodied it in some of his greatest works it would be merely a matter of curious investigation for the anthropologist and student of folk-lore. In the eschatological myth which closes the Republic he tells the story how Er, the son of Armenius, miraculously returned to life on the twelfth day after death and recounted the secrets of the other world. After death, he said, he went with others to the place of judgment and saw the souls returning from heaven and from purgatory, and proceeded with them to a place where they chose new lives, human and animal. "He saw the soul of Orpheus changing into a swan, Thamyris becoming a nightingale, musical birds choosing to be men, the soul of Atalanta choosing the honours of an athlete. Men were seen passing into animals and wild and tame animals changing into each other." After their choice the souls drank of Lethe and then shot away like stars to their birth. There are myths and theories to the same effect in other dialogues, the Phaedrus, Meno, Phaedo, Timaeus and Laws. In Plato's view the number of souls was fixed;
birth therefore is never the creation of a soul, but only a transmigration from one body to another. Plato's acceptance of the doctrine is characteristic of his sympathy with popular beliefs and desire to incorporate them in a purified form into his system. Aristotle, a far less emotional and sympathetic mind, has a doctrine of immortality totally inconsistent with it. In later Greek literature the doctrine appears from time to time; it is mentioned in a fragment of Menander (the Inspired Woman) and satirized by Lucian (Gallus § 18 seq.). In Roman literature it is found as early as Ennius, who in his Calabrian home must have been familiar with the Greek teachings which had descended to his time by way of the Magi. In the last passage of his Annales, a Roman history in verse, Ennius told how he had seen Homer in a dream, who had assured him that the same soul which had animated both the poets had once belonged to a peacock. Persius in one of his satires (vi. 9) quotes at Ennius for this; it is referred to also by Lucretius (i. 124) and by Horace (Epist. II. 1. 52). Virgil works the idea into his account of the Underworld in the sixth book of the Aeneid (vv. 724 seq.). It persists in antiquity down to the latest classic thinkers, Plotinus and the other Neoplatonists.

Attempts have been made with little success to find metempsychosis in early Jewish literature. But there are traces of it in Philo, and it is definitely adopted in the Kabbala. Within the Christian Church it was held during the first centuries by isolated Gnostic sects and by Jews; but in the 4th and 5th centuries, but was invariably repudiated by orthodox theologians. In the middle ages these traditions were continued by the numerous sects known collectively as Cathari. At the Renaissance we find the doctrine in Giordano Bruno, and in the 17th century in the theosophist van Helmont. A modified form of it was adopted by Swedenborg. During the classical period of German literature metempsychosis attracted much attention: Goethe pictured with the idea, and it was taken up more seriously by Lessing, who borrowed it from Charles Bonnet, and from Herder. It has been mentioned with respect by Hume and by Schopenhauer. Modern theosophy, which draws its systems from Gnosticism, has taken metempsychosis as a cardinal tenet; it is, says a recent theosophical writer, "the master-key to modern problems," and among them to the problem of heredity.

Other attempts to picture the somewhat narrow circle of theosophists there is little disposition to accept the doctrine: but it may be worth while to point out that there are two fatal objections to it. The first is that personal identity depends in memory, and we do not remember our previous incarnations. The second is that the soul, whatever it may be, is influenced throughout all its qualities by the qualities of the body: modern psychology discredits the idea that the soul is a self-independently existing thing which can pass independently from one body to another. If (to suppose the impossible) the soul of a dog were to pass into a man's body it would be so changed as to be no longer the same soul; and so, in a less degree, of change from one human body to another.

See A. Bertholet, The Transmigration of Souls (trans. from the German by H. J. Chaytor); E. Rohde, Psyche. (H. St.)

Meteor (Gr. μετέωρος, literally "things in the air," from μετέρω, beyond, and ἀέρ, to lift up), a term originally applied by the ancient Greeks to many atmospheric phenomena—rainbows, halos, shooting stars, &c.—but now specially restricted to those luminous bodies known as shooting stars, falling stars, fireballs and bolides. Though these objects only become visible in the atmosphere they are extra-terrestrial planetary bodies, and properly belong to the domain of astronomy. The extra-terrestrial bodies which happen to find a resting-place on the earth are studied under the name of meteories (q.v.).

In ancient times meteors were supposed to be generated in the air by inflammable gases. Isolated fireballs and star showers had been occasionally observed, but instead of being attentively watched they had been neglected, for their apparitions had always mankind with dread, and superstition attributed to them certain malevolent influences. It was the brilliant exhibition in November 1833 that, in modern times particularly, attracted earnest students to investigate the subject of meteors generally, and to make systematic observations of their apparitions on ordinary nights of the year. Historical records were searched for references to past meteoric displays, and these were tabulated and compared. The attention devoted to the matter soon elucidated the phenomena of meteors, and proved them to be small planetary bodies, practically infinite in numbers and inimitable in the extent and variety of their orbits.

The various kinds of meteors are probably but different manifestations of similar objects. Perhaps the most important meteors are those which, after their bright careers and loud detonations, descend upon the earth's surface and can be submitted to close inspection and analysis (see Meteorites). The fireball or bolide (Gr. βολίς, a missile) comes next in order from its size and conspicuous effects. It may either be interspersed with many smaller meteors in a shower or may be isolated. The latter usually move more slowly and approach rather near to the earth. The ordinary shooting stars vary from the brilliancy of a first- to a fifth-magnitude star. They exhibit a great diversity in paths, motions and colours. The smallest and most numerous class are the telescopic meteors invisible to the naked eye. They range from the 7th magnitude to the smallest object perceptible in large telescopes.

The altitudes at which these bodies are visibly presented to us differ in individual cases. More than a thousand observations in duplicate have been made of the paths of identical meteors seen from two stations many miles apart. These pairs of observations have shown a parallax from which the elevation of the objects above the earth, the lengths and directions of their courses, could be computed. The average heights are from 80 to 40 m. A few, however, first appear when higher than 80 m. and some, usually slow-moving meteors, descend below 40 m. But altitudes beyond 100 and within 20 m. are rare:

30 of the November Leonids give a mean height of 841 to 571 m. of the August Perseids... 80 to 54 m.

When the length of a meteor's course is known and the duration of its flight has been correctly estimated it is easy to compute the velocity in miles of servate systems. The velocity of a meteoric shooting star is, however, comprised within one second, and it is only rarely that such short time intervals can be accurately taken. The real velocities derived from good observations are rarely, if ever, under 7 or 8 m. per second, or over 60 or 70 m. per second. In a few exceptional cases abnormal speed has been indicated on good evidence. The slower class of meteors overtaking the earth (like the Andromedids of November) have a velocity of about 8 or 10 m. per second, while the swifter class (meeting the earth like the Leonids of November) have a velocity of about 44 m. per second.

When the members of a shower are observed with special regard to their directions it is seen that they diverge from a common focus. The apparent scattering or diversity of the flights is merely an effect of perspective upon objects really traversing parallel lines. The centre upon which the observed paths converge is called the radiant point or, shortly, the radiant. On every night of the year there are a great number of these radiants in action, but the large majority represent very attenuated showers. In 1876 the number of radiants known was 850, but about 500 have been determined up to the present time. These are not all the centres of servate systems, however: many of the positions being multiple observations of the same showers. Thus the August Perseids, the returns of which have been witnessed more frequently than those of any other meteoric stream have had their radiant point fixed on more than 250 occasions.

There appear to be moving and stationary radiants, contracted and diffused radiants, and long-enduring and brief radiants. The Perseids are visible from about the 11th of July to the 20th.
of August, the radiant having a daily motion of about 1° R.A. to E.N.E. The Lyrids also vary in the position of their radiant,
but the Orionids form a stationary position from about the 9th
to the 24th of October. A large proportion of the ordinary
feeble showers also appear to be stationary.
Solids bodies (chiefly stone or stone and iron) enter the atmo-
sphere from without at all conceivable angles and at a velocity
of about 26 m. per second, while the earth's orbital velocity is
about 183 m. per second. Thus rapidly penetrating the air
heat is generated, the meteor becomes incandescent, and the
phenomena of the streak or train is produced. Before the
object can pierce the dense lower strata of air its material is usu-
ally exhausted, but on rare occasions it withstands the fiery ordeals,
and fragments of the original mass fall upon the earth's
surface.
Multitudes of meteors infest space. On a clear moonless
night one person may count eight or ten shooting stars in an
hour. But there are more than twice as many visible in the
early morning hours as in the evenings, and during the last half
of the year there are also more than twice as many visible
as during the first half. It is computed that twenty millions of
meteors enter the atmosphere every day and would be visible
to unassisted vision in the absence of sunlight, moonlight and
clouds; while if telescopic meteors are included the number will
be increased twofold. Ordinary meteors, in the region of the
plane of the ecliptic, are usually found only by the gaps
between the orbits of intervals of about
250 m. In special showers, however, they are much closer.
In the rich display of the 12th of November 1833, the average
distance of the particles was computed as about 15 m.,
in that of the 27th of November 1851 as about 20 m., and in that
of the 27th of November 1872 as about 35 m.
The meteors, whatever their dimensions, must have motions
around the sun in obedience to the law of gravitation in the
same manner as planets and comets—that is, in conic sections
of which the sun is always at one focus. The great variety in
the directions of the paths of meteors proves that they are
not directed from the plane of the ecliptic; hence their orbits
are not like the orbits of planets and short-period comets, which
are little inclined, but like the orbits of parabolic comets, which
are often have great inclinations.

Historical records supply the following dates of abundant
meteoric displays:

Many meteorites exhibit the green line of magnesium as a
principal constituent. Professor N. von Kondol remarked in
the fireball of 1873 (July 26) the lines of magnesium and
sodium. Other lines in the red and green have been detected
and found by comparison with the lines of march gas. Bright
meteorites often emit the bluish-white light suggestive of burning
magnesium. In addition to magnesium and sodium the lines of
potassium, lithium and also the carbon flittings exhibited in
cometary spectra, has been seen.

Meteoric observation has depended upon rough and hurried
eye estimates in past years, but the importance of attaining
greater accuracy by means of photography has been recognized.
At several American observatories, and at Vienna, fairly suc-
essful attempts were made in November 1898 to photograph
a sufficient number of meteor-trails to derive the Leonid radiant,
and the mean position was at R.A. 15° 33' Dec. +22° 12'.
But the materials obtained were few, the shower having
proved inexpressible. The photographic method appears to
have practically failed during recent years, since there has...
METEORA—METEORITE

been no brilliant display upon which to test its capacity. Really large meteors can be satisfactorily photographed, but small ones leave no impression on the plates.

Meteors look larger than they are, from the glare and flaming effect due to their incandescent or incandescent combustion. The finer meteors or meteors the air only weigh a few hundred or, at most, a few thousand pounds, while the smallest shooting stars visible to the eye may probably be equal in size to coarse grains of sand, and still be large enough to evolve all the light presented by them. (W. F. D.)

METEORA, a group of monasteries in Thessaly, in the northern side of the Peneius valley, not quite 20 m. S. of Trikala, and near the village of Kálabaka (ancient Aeginium, medieval Stagou or Stagou), from the Cambunian chain two masses of rock are thrust southward into the plain, surmounted by isolated columns from 85 to 300 ft. high, "some like gigantic tusks, some like sugar-loaves, and some like vast stalagmites," but all consisting of iron-grey or reddish-brown conglomerate of gneiss, mica-slate, syenite and greenstone. The monasteries stand on the summit of these pinnacles; they are accessible only by aid of rope and net worked by a windlass from the top, or by a series of almost perpendicular ladders climbing the cliff. In the monastery of St Stephen, the peak on which it is built does not rise higher than the ground behind, from which it is separated by a deep, narrow chasm, spanned by a drawbridge. Owing to the confined area, the buildings are closely packed together; but each monastery contains beside the monks' cells and water-cisterns, at least one church and a refectory, and some also a library. At one time they were fourteen in number, but now not more than four (the Great Monastery, Holy Trinity, St Barlaam's and St Stephen's) are inhabited by more than two or three monks. The present church of the Great Monastery was erected, according to Leake's recording of the local inscription, in 1388 (Björnstell, the Swedish traveller, had given 1371), and it is one of the largest and handsomest in Greece. A number of the manuscripts from these monasteries have now been brought to the National Library at Athens. Aeginium is described by Livy as a strong place, and is frequently mentioned during the Roman wars; and Stagou appears from time to time in Byzantine writers.

See W. M. Leake, Northern Greece (4 vols., London, 1835); Professor Kriek in Zeitschr. f. allg. Erdk. (Berlin, 1858); H. F. Tozer, Researches in the Highlands of Turkey (1869); L. Heuzez and H. Daumet, Mission archéologique de Macedoine (Paris, 1875); where is there a map of the monasteries and their surroundings; Guido-Joanne; Orbis, vol. ii. (Paris, 1894).

METEORITE, a mass of mineral material which has reached the earth's surface from outer space. Observation teaches that the fall of a meteorite is often preceded by the flight of a fireball (see METEOR) through the sky, and by one or more loud detonations. It was inferred by Chladni (1794) that the fireball and the detonations result from the quick passage of the meteorite through the earth's atmosphere.

The fall of stones from the sky, though not credited by scientific men till the end of the 18th century, had been general and again placed on record. One of the most famous of meteorites fell in Phrygia and was worshipped there for many generations under the name of Cybele, the mother of the gods. After an oracle had declared that possession of the stone would secure to the Romans a continual increase of prosperity, it was demanded by them from King Attalus about the year 264 B.C., and taken with great ceremony to Rome. It is described by the historian as 'a black stone, in the figure of a cone, circular below and ending in an apex above.' Plutarch relates the fall of a stone in Thrace about 470 B.C., during the time of Pindar, and according to Pliny the stone was still preserved in his day, 500 years afterwards. Both Diana of the Ephesians "which fell down from Jupiter," and the image of Venus at Cyprus, appear to have been conical or pyramidal stones. One of the holiest relics of the Moslems is preserved at Mecca, built into a corner of the Kaaba; its history goes back far beyond the 7th century; the description of it given to Dr Partsch suggests that the stone had fallen from the sky. The oldest existing meteorite of which

the fall is known to have been observed is that which fell at Ensisheim in Elsass on the 10th of November 1492. It was seen to strike the ground and was immediately dug out; it had penetrated to a depth of 5 ft. and was found to weigh 260 lb. It was long suspended by a chain from the roof of the parish church, and is now kept in the Rathhaus of the town.

It was not till scientific men gave credence to the reports of the fall of heavy bodies from the sky that steps were taken for the formation of meteorite collections. The British Museum (Natural History) at South Kensington now contains specimens belonging to 56 distinct falls; of these falls 325 have been actually observed; the remaining specimens are inferred to have come from outer space, because their characters are similar to those of the masses which have been seen to fall. Of these meteorites the following two have fallen within the British Isles:

Meteoritic falls are independent of thunderstorms and all other terrestrial circumstances; they occur at all hours of the day and night, and at all seasons of the year; they favour no particular latitudes. The number of stones which reach the earth's surface from one fireball is very variable. In each of the two Yorkshire falls only one stone was found; the Guernsey County meteor yielded 30; at Toulouse, as many as 350 are estimated to have fallen; at Hesse, over 500; at Knyahinya, more than 1200; at L'Aigle, from 1000 to 2000; at both Pultusk and Mocs no fewer than 100,000 are estimated to have reached the earth's surface. The largest single mass seen to fall is one of those which came down at Knyahinya, Hungary, in 1866, and weighed 347 lb.; but far larger masses, inferred from their characters to be meteorites, have been seen in the British Museum (Natural History), before rusting weighed 33 tons; the largest of the masses brought by Liet. Peary from western Greenland weighs 364 tons. A mass found at Bacubirito in Mexico is 13 ft. long, 6 ft. wide and 5 ft. thick, and is estimated to weigh 20 tons.

From observations of the path and time of flight of the luminous meteor it is calculated that meteorites enter the earth's atmosphere with absolute velocities ranging from 10 to 45 m. a second; but the speed of a meteorite after the whole of the resisting atmosphere has been traversed is extremely small and comparable with that of an ordinary falling body. According to Professor A. S. Herschel's experiments, the meteorite which fell at Middlesbrough must have struck the ground with a velocity of only 412 ft. a second. In the case of the Hesse fall, several stones fell on the ice, which was only a few inches thick, and rebounded without breaking the ice or being broken themselves. The depth to which a meteorite penetrates depends on the speed, form, weight and density of the meteorite and on the nature of the ground. At Stannern a meteoric stone weighing 2 lb. entered to a depth of only 4 in., the large Knyahinya stone already mentioned made a hole 11 ft. deep.

The area of the earth's surface occupied by towns and villages being comparatively small, the probability of a shower of stones falling within a town is extremely minute; the likelihood of a living creature being struck is still more remote. The first Yorkshire stone, that of Wold Cottage, struck the ground only 10 yds. from a labourer; the second, that of Middlesbrough, fell on the railroad only 40 yds. away from some platelayers at
work; a stone completely buried itself in the highway at Kaba; one fell between two carter's on the road at Charsonne, throwing the ground up to a height of 6 ft.; the 'Tournois-la-Grosse meteorite' broke the parapet, and was broken itself; the Kitchener stone fell within a few paces of a little girl; the Angers stone fell close to a lady standing in her garden; the Braunau mass went through the roof of a cottage; at Macao, in Brazil, where there was a shower of stones, some oxen are said to have been killed; at Nedagolla, in India, a man was so near that he was stunned by the shock; while at Mhow, also in India, a man was killed in 1827 by a stone which is a true meteorite, and is represented by fragments in museum collections.

Though the surface of a meteorite stone becomes very hot by contact with the mineral composition of the meteorite it is cooled again during the later and slower part of the flight. Meteorites are generally found to be warm to the touch if immediately dug out; at the moment of their impact they are not hot enough to char woody fibre on which they chance to fall, nor is the surface then soft, for terrestrial matter with which the surface comes into contact makes no impression upon the meteorite. Where many stones fall at the same time they are generally distributed over a large area elongated in the direction of the flight of the luminous meteor, and the largest stones generally travel farthest. At Hessle, for instance, the stones were distributed over an area of 17 miles by 1½ miles.

Meteorites are almost invariably found to be completely covered with a thin crust such as would be caused by intense heating of the material for a short time; its thinness shows the slight depth to which the heat has had time to penetrate. They are presumably cold and invisible when they enter the earth's atmosphere, and become heated and visible during their passage through the air; doubtless the greater part of the superficial material fizzes off as the result of the sudden heating and is left behind floating in the air as the trail of the meteor. The crust varies with the early part of the flight through the air, is generally black; it is in most cases dull but is sometimes lustrous; more rarely it is dark-grey in colour. Each stone of a shower is in general completely covered with crust; but occasionally, as in the case of the Butsura fall, stones found some miles apart fit each other closely and the fitting surfaces are uncrusted, showing that a meteorite may break up during a late and cool stage of the flight through the atmosphere. A meteorite is generally covered with pittings which have been compared in size and form to thumbmarks; the pittings are probably occasioned by the explosive nature of the decomposition of the superficial material. As picked up, complete and covered with crust, meteorites are always irregularly-shaped fragments, such as would be obtained on breaking up a rock presenting no regularity of structure.

About one-third, and those the most common, of the chemical elements at present recognized as constituents of the earth's crust have been met with in meteorites; no new chemical element has been discovered. The most frequent or plentiful in their occurrence are: aluminium, calcium, carbon, iron, magnesium, nickel, oxygen, phosphorus, silicon and sulphur; while less frequently or in smaller quantities and found antimony, arsenic, chlorine, chromium, cobalt, copper, hydrogen, lithium, manganese, nitrogen, potassium, sodium, strontium, tin, titanium, vanadium. The existence of minute traces of several other elements has been announced; of these special mention may be made of gallium, gold, iridium, lead, platinum and silver. Iron occurs chiefly in combination with nickel, and phosphorus almost always in combination with both nickel and iron (schreibersite); carbon occurs both as indistinctly crystalized diamond and as graphitic carbon, the latter generally being amorphous, but occasionally having the forms of cubic crystals (cliftonite); free phosphorus has been found in one meteorite; free sulphur has also been observed, but may have resulted from the decomposition of a sulphide since the fall of the stone.

Of the mineral constituents of meteorites, the following are by many mineralogists regarded as still unrepresented among native terrestrial products: cliftonite, a cubic form of graphic carbon; phosphorus; various alloys of nickel and iron; miorianite, silicide of carbon; cohenite, carbide of iron and nickel (corresponding to cementite, carbide of iron, found in artificial iron); schreibersite, phosphide of iron and nickel; trolite, protochloride of iron; asmanite, a single refractive mineral with the chemical composition of olivaholtham.; deinorobite; a silicate intermediate in chemical composition to pyroxene and nepheline.

Meteorites are conveniently distributed into three classes, which pass more or less gradually into each other: the first (siderolites) for meteorites in which the mass is mainly of metallic iron alloyed with nickel; only nine of them have been actually seen to fall; the second (sidereolites) includes those in which metallic iron (alloyed with nickel) and stony matter are present in large proportion; few of them have been seen to fall; those of the third class (aerolites or meteoric stones) consist almost entirely of stony matter; nearly all have been seen to fall.

In the meteoric irons the iron generally varies from 80 to 95% and the nickel from 6 to 10%; the latter is generally alloyed with phosphorus to about 20% and generally figures of 10% nickel; it is distinguished by special names (kamacite, taenite, plessite). Trolite is frequently present as plates, veins or large nodules, sometimes surrounded by graphite; schreibersite is almost always present, and occasionally also daubrèelite. The composition and the structure of meteoric iron are well shown by the figures generally called into existence when a polished surface is etched by means of acids or bromine-water; they are due to the inequality of the etching action on thick and thin plates of various constituents, the plates being composed chiefly of two nickel-iron varieties, kamacite and taenite. A difference in the corrosion of the plates (petrology) falls up the spaces formed by the intersection of the joint plates of kamacite and taenite; it is probably not an independent substance but an intimate intergrowth of kamacite and taenite. The figures were first observed in 1808 and are generally termed "Widmanstätten figures" in honour of their discoverer; the plates which give rise to them are parallel to the faces of the regular octahedron, and such masses have therefore an octahedral structure. A small number of the remaining masses have cubic cleavage; instead of Widmanstätten figures they yield fine linear furrows when etched; the furrows traverse the octahedral planes. The cube of a meteoric iron has a unique shape and have directions such as would result from the turning of the cube about an octahedral face; they are known as "Neumann lines." For meteoric irons of cubic structure the percentage of nickel is lower than 6 or 7; for those of octahedral structure it is higher than 6 or 7; the plates of kamacite are thinner, and the structure therefore finer the higher the percentage of that metal. A considerable number of meteoric irons, however, show no crystalline structure at all, and have percentages of nickel both below and above 7; it has been suggested that each of these masses may once have had crystalline structure and that it has disappeared as a result of protracted heat throughout the mass while the meteorite has been passing near a star.

An investigation of the changes of the magnetic permeability of the Sacramento meteoric iron with changing temperature led Dr S. W. J. Smith to infer that the magnetic behaviour can only be explained by imagining the meteorite to consist
METEOROLOGY

largely of plates of nickel-iron containing about 7% of nickel (kamacite), separated from each other by thin plates of a nickel-iron constituent (taenite), containing about 27% of nickel and having different thermomagnetic characters from those of kamacite; he suggests, however, that taenite is made of a definite chemical compound but a eutectic mixture of kamacite and a nickel-iron compound containing not less than 37% of nickel. About eleven out of every twelve of the known meteoric stones belong to a division to which Rose gave the name "chondritic" (χονδρίτης, a grain); they present a very fine-grained but crystalline matrix or paste, consisting of olivine and enstatite or bronzite, with more or less nickel-iron, troilite, chromite, augite and troilitic feldspar; through this paste are disseminated round chondrules of various sizes and generally with mineral composition as the matrix; in some cases the chondrules consist wholly or in great part of glass. Some meteorites consist almost solely of chondrules; others contain only few; in some cases the chondrules are easily separable from the surrounding material. In mineral composition chondritic meteorites approximate more or less to terrestrial lherzolites. A few meteorites belonging to the chondritic division are remarkable as containing carbon in combination with hydrogen and oxygen; those of Alais and Cold Bokkeveld are good examples.

The remaining meteoric stones are without chondrules and contain little or no nickel-iron; of these the following may be mentioned as illustrative of the varieties of mineral composition: Juvinas, consisting essentially of anorthite and augite; Petersburg, of anorthite, augite and olivine, with a little chrome-iron and nickel-iron (both Juvinas and Petersburg may be compared to terrestrial basalts); Sheerhauty, chiefly of augite and maskelynite; Angora des Reis, almost wholly of augite, but olivine is present in small proportion; Buste, of a little chrome-iron and a little troilitic feldspar, with some nickel-iron, olivinite and olivine; Bishopville, of enstatite and troilitic feldspar, with occasional augite, nickel-iron, troilite and chromite; Roter, of olivine and bronzite; and Chassiron, consisting of olivine with enclosed chromite, and thus mineralogically identical with terrestrial dunite.

Almost all meteoric stones appear to be made up of irregular angular fragments, and some of them bear a close resemblance to volcanic tuffs. In the large group of chondritic stones, chondrules or spherules, some of which can only be seen under the microscope while others reach the size of a walnut, are embedded in a matrix apparently made up of minute splinters such as might arise from the fracture of a solid body. In fact, until recently it was thought by some mineralogists that the chondrules owe their form, not to crystallization, but to friction, and that the matrix was actually produced by the wearing down of the chondrules through frequent collision with each other as oscillating components of a comet or during repeated ejection from a volcanic vent of some small celestial body. Chondrules have been observed, however, presenting forms and crystalline surfaces incompatible with such a mode of formation, and others have been described which exhibit features resulting from mutual interference during their growth. The chondritic structure is different from anything which has yet been observed in terrestrial rocks, and the chondrules are distinct in character from those observed in perlitic and obsidian. It is now generally believed that the structural features of meteoric stones are the result of hurriced crystallization.

No organized matter has been found in meteorites and they have brought us, therefore, no evidence of the existence of living beings outside our own world.

AUTHORITIES.—The literature consists chiefly of memoirs published by individual societies. The following separate works may be consulted: A. Brezina, Die Meteoriten. Sammlung d. k.k. min. Hofkabinettes in Wien (Vienna, 1896); A. Brezina u. E. Cohen, Die Structur und die Zusammensetzung der Meteoriten (Stuttgart, 1886-1888); P. S. D. de Montesquieu, Météorologique historique et physique sur les chutes des pierres (Orleans, 1812); Chladni, Uber den Ursprung der von Polack gefundenen und anderer der Jahresentermasen (Riga, 1794), and Uber Erste- and Uber die mit denselben herabgefallenen Massen (Vienna, 1819); E. Cohen, Meteoritenkunde (Stuttgart, 1894-1905); L. Fletcher, An Introduction to the Study of Meteorites, 10th ed. (London, 1916); F. King, Remarks concerning Stones said to have fallen from the Clouds both in these Days and in Ancient Times (London, 1796); S. Meunier, Méthodes (Paris, 1884); C. Rammelsberg, Die Chemische Natur der Meteoriten (Berlin, 1870-1879); G. Rose, Beschreibung und Einthaltung der Meteoriten (Berlin, 1864); G. Tschermak, Die meteorologische Beschaffenheit der Meteoriten (Stuttgart, 1883-1885); E. T. Wülfing, Die Meteoriten in Sammlungen und ihre Literatur (Tübingen, 1897).

METEOROLOGY (Gr. μετεωρός, and θέρας, i.e. the science of things in the air), the modern study of all the phenomena of the atmosphere of gases, vapours and dust that surrounds the earth and extends to that unknown outer surface which marks the beginning of the so-called interstellar space. These phenomena may be divided either individually or collectively. The collective study has to do with statistics and general average conditions, sometimes called normal values, and is generally known as Climatology (see CLIMATE, where the whole subject of regional climatology is dealt with). The study of the individual items may be either descriptive, explanatory, physical or theoretical. Physical meteorology is again subdivided according as we consider either the changes that depend upon the motions of masses of air or those that depend upon the motions of the gaseous molecules; the former belong to hydrodynamics, and the latter are mostly comprised under thermodynamics, i.e. to their Mechanism.

History.—The historical development of meteorology from the most ancient times is well presented by the quotations from classic authors compiled by Julius Ludwig Ideler (Meteorologia veterum graecarum et romanarum, Berlin, 1832). We owe to the Arabian philosophers some slight advance on the knowledge of the Greeks and Romans; especially as to the optical phenomena of the atmosphere. The Meteorologia Aristotelis (see Zeller, Phil. der Griechen) accords entirely with the Philosophia of Thomas Aquinas, the poetical songs of the troubadours, and the lines of Dante (see the Compend of Nature in Dante's Divina Commedia; London, 1897). Dante's work completed the passage from the ancient mythological treatment of nature to the more rational recognition of one creator and lawgiver that pervades modern science. The progress of meteorology has been coincident with the progress of physics and chemistry in general, as is shown by considering the works of Alhazen (1050) on twilight, Vitello (1250) on the rainbow, Galileo (1607) on the thermometer and on the laws of inertia, on attractions and on the weight of the air, Torricelli (1644) on the barometer, Boyle (1659) on the elasticity of the air in all directions, LaPlace (1775), and Laplace (1780), on the motion of a barometer at sea, W. Thomson (1851), and Bokkeveld, on the effects of heat on the motion of a barometer (1856), and the study of pressure of aqueous vapour (1752), separation of carbonic acid gas from ordinary air; Rutherford (1772), separation of nitrogen; Priestley and Scheele (1775) and Cavendish (1777), separation of oxygen; Lavoisier (1783), general establishment of the character of the atmosphere as a simple mixture of gases and vapour; De Saussure's measurement of relative humidity by the accurate hair hygrometer (1780), Dalton's measurement of vapour tension at various temperatures (1800), Regnault's and Magnes's revision of Dalton's tension of water vapour (1846), and Cavendish's studies of the tension of ice vapour (1801), and the isolation of argon by Rayleigh and Ramsay (1894).

Theoretical meteorology has been, and always must be, wholly dependent on our knowledge of thermodynamics and on mathematical methods of dealing with the forces that produce the motions within the atmosphere. Progress has been due to the most eminent mathematicians at the following approximate dates: Sir Isaac Newton (1670), Leibnitz (1730), Pierre Simon Laplace (1786), Jean Baptiste Joseph Fourier (1822), Jean-Baptiste Joseph Fresnel (1815), Sir George Gabriel Stokes (1851), Hermann von Helmholtz (1857), Lord Kelvin (1860), C. A. Bjerknes (1868), and V. Bjerknes (1906), and to many distinguished followers.

The earliest systematic daily record of local weather phenomena that has survived is that kept by William Merle, rector of Drhy, during seven years 1311-1318: the manuscript is preserved in the Digby MS., Merton College, Oxford, and
was published in facsimile by George G. Symons in 1891. Doubtless many similar monastic diaries have been lost to us. In 1853 Ferdinand II. of Tuscany organized a local system of stations and daily records which extended over and beyond northern Italy. This was the forerunner of numerous meteorological systems in Europe. The records kept during the years 1655-1670 at the Cloister Angelus near Florence were reduced by Libri, professor of mathematics at Pisa, and published in 1830.

The history of meteorology is marked by the production of comprehensive treatises embodying the current state of our knowledge. Such were Louis Cotte's Traité de météorologie (Paris, 1774) and his Mémoires sur la météorologie, supplément au traité (1788); Ludwig Känz's Lehrbuch der Meteorologie (Halle, 1831-1836) and his Verzehrungen (1840; French, 1842; English, 1843); Sir John Herschel's Meteoro. (London, 1840); the splendid series of memoirs by H. W. Brandes in Gehler's Physikalisches Wörterbuch (Leipzig, 1820-1840); E. E. F. W. Schmid's Grundrisse der Meteorologie (Leipzig, 1862); Ferrel's Recent Advances in Meteorology (Washington, 1883); the great works of Julius Hann, as summarized in his Handbuch der Klimatologie (1883; 2nd ed., Stuttgart, 1897; vol. 1. English 1903) and his Lehrbuch der Meteorologie (Leipzig, 1901, 2nd ed. 1909); the extensive studies of J. E. Woeikoff (Voeikof), as presented in his Klima der Erde (Russian 1883, German 1885) and his Meteorologie (Russian 1904).

The development of this science has been greatly stimulated by the regular publication of special periodicals such as the Zeitschrift of the Austrian Meteorological Society, 1866-1885, vol. 21 appearing with vol. 3 of the Meteorologische Zeitschrift of the German Meteorological Society in 1886, and since that date this journal has been jointly maintained by the two societies. The analogous journals of the Royal Meteorological Society, London, 1830 to date, the Scottish Meteorological Society, 1860 to date, the Meteorological Society of France, 1858 to date, the Italian Meteorological Society, and the American Meteorological Journal (1878-1885), have all played important parts in the history of meteorology. On the other hand, the Annals of the Central Meteorological Office at Paris, the Archives of the Deutsche Seewarte at Hamburg, the Annals and the Repertorium of the Central Physical Observatory at St Petersburg, the Annals of the Central Meteorological Office at Rome, Bulletin of International Simultaneous Met. Obs. and the Monthly Weather Review of the Weather Bureau at Washington, the Abhandlungen of the Royal Prussian Meteorological Institute at Berlin, the Meteorological Papers of the Meteorological Office at Bonn, the numerous memoirs and treatises by leading meteorologists, have represented the important official contributions of the respective national governments to technical meteorology.

The recent international union for kite and balloons has given rise to two important publications, i.e. the Veröffentlichungen of the International Commission for Scientific Aerostatics (Strassburg, 1905, et seq.), devoted to records of observations, and the Beiträge zur Physik der freien Atmosphäre (Strassburg, 1904, et seq.), devoted to research. The necessity of studying the atmosphere as a unit and of securing uniform accuracy in the observations has led to the formation of a Central International Meteorological Committee (of which in 1909 the secretary was Professor Dr G. Helmman of Berlin, and the president Dr W. N. Shaw of London). Under its directions conferences and general congresses have been held, beginning with that of 1872 at Leipzig. Its International Tables, Atlas of Clouds, Code of Instructions, and Forms for Climatological Publications illustrate the activity and usefulness of this committee.

Modern meteorology has been developed along two lines of study, based respectively on maps of monthly and annual average and on daily weather maps. The latter study seems to have been begun by H. W. Brandes in Leipzig, who first, about 1820, compiled maps for 1783 from the data collected in the Ephemerides mannheimerensis, and subsequently published maps of the European storms of 1820 and 1821. Simultaneously with Brandes we find William C. Redfield in New York compiling a chart of the hurricane of 1821, which was published in 1831, and was the first of many memoirs by him on hurricanes that completely established their rotary and progressive motion. Soon after this Piddington and Sir William Reid began their studies of the balloon on the continent. About 1825 James Pollard Espy, in Philadelphia, began the publication of telegrams as to the motive power of thunderstorms and tornadoes, and in 1842 was appointed "meteorologist to the U.S. government" and assigned to work in the office of the surgeon-general of the army, where he prepared daily weather maps that were published in his four successive "Reports." In 1848 the three American leaders united in letters to Professor Joseph Henry, secretary of the Smithsonian Institution, urging that the telegraph be used for collecting data for daily maps and that the proper action was taken in 1849, the Smithsonian maps began to be carried on the U.S. and were displayed in public from 1853 onwards. Meanwhile in England James Glashier, with the help of the daily press, carried out similar work, publishing his first map in 1851 as soon as daily weather maps of sufficient extent could be promptly prepared by the help of the telegraph. The destructive storm of the 14th of November 1854, in the Crimea gave U. J. J. Le Verrier, at Paris, an opportunity to propose the proper action, and his proposals were immediately adopted by the secretary of the Royal Society, Sir John Ince, and by the Prince of Wales. In 1855 the emperor ordered the director-general of government telegraph lines to co-operate completely with Le Verrier in the organization of a bureau of telegraphic meteorology. The International daily bulletin of the Paris Observatory began to be printed in regular form on the 1st of January 1858, and the daily map of isobars was added to the text in the autumn of 1863. The further development of this bulletin, the inclusion of British and ocean reports in 1861, the addition of special storm warnings in 1863, the publication of the Atlas des mouvements généraux contrôlant l'atmosphère in 1865, the study of local thunderstorms by Ducommun, the work of Mariotte and Schmid's Hercule, and the work of Fitzroy, Buys-Ballot, Buchan, Glashier and Thomson in Great Britain, parallel the analogous works of the American students of meteorology and form the beginnings of our modern dynamic meteorology.

The details of the historical development of this subject are well given by Hugo Hildebrand-Hildebrandsson and Léon Teisserenc de Bort in their joint work, Les Bases de la météorologie dynamique (Paris, 1897). The data in meteorographia have been collected by Hann in his Lehrbuch. Many of the original memoirs have been reproduced by Brillouin in his Mémoires originaux (Paris, 1900), and in Cleveland Abbe's Mechanics of the Earth's Atmosphere (vol. i., 1891; vol. ii., 1903).

The publication of daily weather charts and forecasts is now carried on by all civilized nations. The list of government bureaux and their publications is given in Bartholomew's Atlas (vol. iii., London, 1899). Special establishments important for upper atmospheric conditions are maintained at Paris, Berlin, Copenhagen, St Petersburg, Washington and Strasbourg.

The general problems of climatology (1900) are best presented in the Handbook of Dr Julius Hann (2nd ed., Stuttgart, 1897). The general distribution of temperature, winds and pressure over the globe was first given by Buchan in charts published by the Royal Society of Edinburgh in 1866, and again greatly revised and improved in the volume of the Challenger reports devoted to meteorology. The most complete atlas of meteorology is Buchan and Herbertson's vol. iii. of Bartholomew's Atlas (London, 1899). Extensive works of a more special character have been published by the London Meteorological Office, and the Deutsche Seewarte for the Atlantic, Pacific and Indian Oceans. Daily charts of atmospheric conditions of the whole northern hemisphere were published by the U.S. Weather Bureau from 1875 to 1883 inclusive, with monthly charts, the latter were continued through 1889. The physical problems of meteorology were discussed in Ferrel's Recent Advances in Meteorology (Washington, 1897). Mathematical aspects of this subject will be found in the author's collection known as The Mechanics of the Earth's Atmosphere; the memoirs by Helmoltz and Von Bezold contained in the col. vol. have been made by Brillouin (Paris, 1898), entitled Vents contigus et nuages. A general summary of our knowledge of the mechanics and physics of the atmosphere is contained in the Recherches sur International Cloude Work, by F. H. Bigelow (Washington, 1900). The extensive Lehrbuch (Leipzig, 1901: 2nd ed., 1906) by Dr Julius Hann is an authoritative work. The optical
METEOROLOGY

The question of whether free ozone exists in the atmosphere is still debated, but there seems to be no satisfactory evidence of its presence, except possibly for a few minutes in the neighbourhood of a thunderstorm. The proportion of the principal gases up to considerable altitudes can be calculated with close approximation by assuming a quiescent atmosphere and the ordinary laws of diffusion. An elastic pressure, such as the earth's, actually shows that the rapid convection going on in the atmosphere changes these proportions and brings about a fairly uniform percentage of oxygen, nitrogen and carbonic acid gas up to a height of 10 km.

**Fundamental Physical Data**

There can be no proper study of meteorology without a consideration of the various physical properties of the atmosphere gases and vapours, each of which plays an independent part, and yet also reacts upon its neighbours.

Atmospheric air is a mixture of nitrogen, oxygen, aqueous vapour, carbonic acid gas (carbon dioxide), ammonia, argon, neon, helium, with slight traces of free hydrogen and hydro-carbons. The proportions in which these gases are present are quite constant, except that the percentage of aqueous vapour is subject to large variations. In an atmosphere that is subject to the variation of the temperature of 0°C, as that at Calcutta, the water may be 23% of the whole weight of any given volume of air. When this aqueous vapour is entirely abstracted, the remaining dry gas is found to have a very uniform constitution in all regions and at all altitudes where examination has been carried out. In this so-called dry atmosphere the relative weights are about as follows: Oxygen, 23.16; nitrogen and argon, 76.77; carbonic acid, 0.04; ammonia and all other gases, less than 0.01 in the lower half of the atmosphere but probably less near the surface of the earth.

**Conclusion**

In addition to the gases and vapours in the atmosphere, the mists of dust and the aqueous particles that constitute cloud, fog and haze are also important. As the air is exposed to wind, scorching in summer, and the convection of the mass of the earth, it is probably far less, if indeed it be at all appreciable.

**Conductivity**

Dry air is a poor conductor of heat. Its coefficient of conduction being expressed by the formula: o-000 0658 (1-o-00190 t) where the temperature (t) is expressed in centigrade degrees. This formula states the fact that a plate of air 1 centimetre thick can conduct through its substance for every square centimetre of its area, in one second of time, the difference of temperature between two faces of the plate is 1° C., enough heat to warm 1 gram of water 0-o00 0568° C., or 1 gram of air 0-o00 239° C., or a quantity of air 1 centimetre in thickness, 239 mgm. or 766 millimetres of pressure and 6° C. The figure 0-o180° C. is the thermometric coefficient as distinguished from the first or calorimetric coefficient (0-o00 0658° C.), and shows what great effect on the air the poor conduction has.

**Diathermy**

Dry air is extremely diathermanous or transparent to the transmission of radiant heat. For the moist whole atmosphere the general coefficient of transmission increases as the waves become longer and longer, and a normal sun is too weak to give any kind of the radiant heat at the end of the spectrum and about o-8 at the red. By specific absorption many specific wave-lengths are entirely cut off by the vapours and gases, and it is found that in general the atmosphere may appear to be more transparent to the shortest wave-lengths, Scir of ether the spectrum, but this is not really so. When the zenithal sun's rays fall upon a station whose barometric pressure is 760 mm., then only from 50 to 80% of the total thermal radiations are absorbed, and so the general coefficient of transmission for the thickness of one atmosphere is usually estimated at about 60% of the total thermal radiations. Of course when the rays are more oblique, or when haze, dust or cloud interfere, the transmission
If the relative accuracy of these figures is 1% as estimated by Abbot, then they demonstrate irregular fluctuations of 5%. But different observers and localities vary so much that Abbot estimates the reliability of the mean value, 2-12, to be about 10%. The causes of these variation appear to be due partly to the apparent movement of the sun moving slowly eastward from day to day, and as the variability is comparable with that of other atmospheric data, therefore considered a normal phenomenon. 

The absorption of solar radiation by the atmosphere is apparently explained by the laws of diffuse reflection, selective diffusion and fluorescence in accordance with which each atom and molecule and particle becomes a new centre for the diffusion in all directions of the energy retained within some specific wave-length.
the gram, the second and the centigrade degrees are adopted as units of measure, and differs for each gas. For aqueous vapour in a gaseous state and not near the point of condensation, if the value of the mass of the aqueous vapour that is mixed with the unit mass of dry air, the above equation becomes \( p = m (29.27 + 4.70 \times 0.0413) \). This equation is sometimes known as the Clausius–Clapeyron relation. It may also be properly called the equation of state or the equation for gases, as expressing the fact that the elastic pressure \( p \) depends upon the temperature and the volume of the gas and is not necessarily due to Bridgman. When there is no dry air, the gas pressure may be derived from the earth’s surface by a continent, as, for instance, on a mountain top, or by the ocean, as on a ship sailing over the sea, or in the free air, as in a balloon. Its different values are sufficiently well known to the meteorologist, though most of these are found indirectly in the elaborate discussion of the hypsometric formula published by Angot in 1899 in the memoirs of the Central Meteorological Bureau of France.

**Diffusion.**—In comparison with the convective actions of the weather, it may be said that it is difficult for aqueous vapour to diffuse in the air. In fact, the distribution of moisture is carried on principally by the horizontal convection due to the wind and the vertical convection due to ascending and descending air masses. Diffusion proper, however, comes into play in the first moments of the process of evaporation. The coefficient of diffusion for aqueous vapour from a pure water surface into the atmosphere is about 0.18 according to Stoffel or 0.18 according to Kinkelmann; that is to say, for a unit surface of 1 sq. centimetre, and a unit gradient of vapour pressure of one atmosphere per centimetre, as we proceed from the water surface into the still dry air, at the standard pressure and temperature, and quantity of moisture diffused is 0.18 grams per second. This coefficient increases with the temperature, and is 0.257 at 47°C. But the value of the coefficient of diffusion, diminishes very rapidly at a small distance from the free surface of the water, so that the most important condition facilitating evaporation is the proximity of the water.

**Viscosity.**—When the atmosphere is in motion each layer is a drag upon the adjacent one that moves a little faster than it does. This drag is the so-called molecular or internal friction or viscosity. The coefficient of viscosity in gases is generally connected with the absolute temperature, and its value is given by an equation like the following: \( 0.000 \times 239 (1 + 0.001 \times 6659) \), which is the formula given by Carl Guldberg (Ann. Phys., 1899, xxvii). This expression implies that for air whose temperature is the absolute zero there is no viscosity, but that at a temperature \( \tau \) of 0° C., or 273° on the absolute scale, a force of 0.000 239 grams is required in order to produce a velocity of air 1 cm. per second parallel to the distance from it by 1 centimetre at a uniform rate of 1 centimetre per second.

**Friction.**—The general motions of the atmosphere are opposed by the viscosity of the air as a resisting force, but this is an exceedingly feeble resistance as compared with the obstacles encountered on the earth’s surface and the inertia of the rising and falling masses of warm and cold air. The coefficient of friction used in meteorology is deduced from the observations of the winds and results essentially not from viscosity, but from the resistances of all kinds to which the motion of the atmosphere is subjected. The greater part of this resistance consists of the energy of the moving masses by their division into smaller masses which penetrate the quiet air in all directions. The loss of energy due to friction is considered to be, in general, proportional to the kinetic energy, and if pressure or, if it must be called friction, should perhaps be called convective friction, or, more properly, convective resistance.

The coefficient of resistance for the free air was determined by Mohn and Ferrel by the following considerations. When the winds, temperatures and barometric pressures are steady for a considerable time, as in the trade winds, monsoons and stationary cyclones, it is the barometric gradient that overcomes the resistances, while the resulting wind is deflected to the right (in the Northern Hemisphere) by the influence of the centrifugal force of the coriolis rotation \( \mathbf{a} \) of the earth. The wind, therefore, makes a constant angle \( \mathbf{a} \) with the direction of the gradient \( \mathbf{G} \). There is also a slight centrifugal force to be considered if the winds are circulating with velocity \( v \) and radius \( r \) about a storm centre, but neglecting this we may express the latitude \( a \).

\[
G \sin a = 2 \omega \sin \phi \cos a + v \cos \phi - \tan a.
\]

where \( \phi \) is the connecting wind-speed function \( \phi \) with the gradient component of the pressure in the direction of the wind. These relations give \( v = \omega \sin \phi \tan a \). The values of \( a \) and \( v \) at sea level and at sea were determined by the data for computing the coefficients for oceanic and continental surfaces respectively, expressed in the same units as those used for \( G \) and \( v \). The extreme values of this coefficient of friction were determined by C. Guldberg and Mohr (1899, xxxi) for the free ocean and 0.000012 for the irregular surface of the land. For Norwegian land stations Mohn found \( \phi = 0.1 = 95.5°, \phi = 0.00002845 \). For the North-West North America Elias Loomis found \( \phi = 25.8°, \phi = 0.00008036 \).

**Gravity.**—The weight of the atmosphere depends primarily upon the action of gravity, which gives a downward pressure to every particle. Owing to the elastic compressibility of the air, this downward pressure is converted at once into an elastic pressure in all directions. The force of gravity varies with the latitude and, in any event, works in one direction. Its value is well represented by the formula due to Helmert, \( g = 980 - (1 - 0.0026 \cos 2 \theta)(1 - f \phi) \), where \( \phi \) represents the latitude of the station and \( \theta \) the altitude. The coefficient \( f \) is small, and gives a correction to the earth’s surface by a continent, as, for instance, on a mountain top, or by the ocean, as on a ship sailing over the sea, or in the free air, as in a balloon. Its different values are sufficiently well known to the meteorologist, though most of these are found indirectly in the elaborate discussion of the hypsometric formula published by Angot in 1899 in the memoirs of the Central Meteorological Bureau of France.
were deduced the following tables, published in the *Monthly Weather Review*:

</table>

In this table the second column gives the altitude of the ground at the reel on which the kite wire was wound. The third column shows the average gradient in degrees Fahrenheit per 1000 ft. between the reel at the respective station and a uniform altitude of 5280 ft. above sea-level. The fourth column shows the total reduction to be applied to the temperature at the reel in order to obtain the temperature at the 1 m. level. Above sea-level, these gradients and reductions are based upon observations made only during the six warm months from May to October 1898.

The kite-work at the Blue Hill Observatory has been published in full in the successive Annuals of the Harvard College Observatory, beginning with 1897, vol. xiii. It has been discussed especially by H. H. Clayton with reference to special meteorological phenomena, such as areas of high and low pressure, fair and cloudy weather, the winds and their velocities at different elevations, insolation, radiation, etc., and has served as a stimulus and model for European meteorologists. Kite-work has also been successfully prosecuted at Trappes, Hamburg, Berlin, St Petersburg, and many other European stations. The highest flights that have been attained have been about 8000 meters.

The great work of L. Teisserenc de Bort began with 1897, when he founded his private observatory at Trappes near Paris devoted to the problems of dynamical meteorology. The results of this work have been published in full in the Memoirs of the Central Meteorological Bureau of France for 1897 and subsequent years. Beginning with the sounding balloons devised by Hervieu the late subdirector of the meteorological bureau, added kite work as supplementary to these. In the *Comptes rendus* (1904), he gives the mean temperatures as they result from five years of work, 1899-1903, at Trappes. Out of 258 ascensions of sounding balloons there were 141 this attained 1400 m. or more, and the following table gives the average temperatures recorded in these ascensions. It will be seen that there is a slow decrease in temperature up to 2 km., a rapid decrease thence up to 10 km., and a slow decrease, almost a stationary temperature, between

### New independent establishment.

The new independent establishment, the "Royal Prussian Aerological Observatory," was founded at Lindenberg, under the direction of Dr. Assmann, who has published the results of his work in three volumes of the *Ergebnisse* of that institution, considering it as a continuation of the work done at Berlin and Tegel. In addition to the elaborate publications various summaries have been published, most of which is the chart embodying daily observations with corresponding isotherms at all attainable altitudes, published monthly since January 1903 in the *Deutscher Wetterdienst.* The work of the new observatory and the reliability of the results may be inferred from a statement of the number of ascensions made each year: 1899; 6, 1900; 39, 1901, 169; 1902, 261; 1903, 481; 1904, 513. This large number, combined with 351 voyages of Teisserenc de Bort at Trappes and many others made in England,
Holland and Russia, amounting in all to over 2000, enabled Assmann to compute the monthly and annual means of temperature and wind velocity for each altitude; the German results are given in table at foot of page 269. The results of these numerous ascents, during these six years, have also been grouped into monthly means that have a reliability proportionate to the number of days on which observations were obtained at each level, and we are now able to speak of the annual and even of the diurnal periodicity of temperature at different altitudes in the free air with considerable confidence.

Some of the most important conclusions to be drawn from the best recent work were published by Hann either in special memoirs or in his Lehrbuch, from which we take the following table. The actual temperatures given in this table have only local importance, but the differences or the vertical gradients doubtless hold good over a large portion of Europe if not of the world.

### METEOROLOGY

The differences of temperature between any layer and those above it and below it, or the vertical gradients at each level go through annual periodical changes quite analogous to those derived from mountain observations; the most rapid falls of temperature, or the largest vertical gradients in the free air occur on the 1st Moving dates over Europe:

The values above given as deduced from 141 high ascensions at Trappes show that between 11 and 14 km. there was no appreciable diminution of temperature, in other words, the air is warmer than could be expected and therefore has a higher potential temperature. This fact was first confirmed by the Berlin ascensions, and is now recorded as well by all observers. The altitude of the base of this warm stratum is about 12 km. in areas of high pressure and 10 km. in areas of low pressure. It is higher as we approach the tropics and above ordinary balloon work near the equator if indeed it exists there. At first this unexpected warmth was considered as possibly a matter of error in the meteorographs, but this idea is now abandoned. Assmann suggested that the altitude is that of the highest cirrus, from which Clevland Abbe inferred that it had something to do with the absorption of the solar and terrestrial heat by dissolving cirrus. But the most plausible explanation for the high temperature was published simultaneously in September 1908 by W. J. Humphreys of Washington, and Ernest Gold of London.

The daily diagrams in Das Wetter show that both the irregular and the periodic and the geographic variations of temperature in the upper strata are unexpectedly large, almost as large as at the earth's surface, so that the uniform temperature of space that was formerly supposed to prevail at the upper air must be abandoned for, if at all, far above the level to which sounding balloons have as yet attained. It is evident that both horizontal and vertical convection currents of great importance really occur at these great altitudes. These upper currents cannot be due to any very local influence at the earth's surface, but only to the interchange of the air over the oceans and continents or between the polar and equatorial regions. They constitute the important feature of the so-called general circulation of the atmosphere; and it is true, as mistakenly thought of as defined to lower levels; their general direction is from west to cast over all parts of the globe as far as yet known, showing that they are controlled by the rotation of the earth. It is likely that masses of air having special temperature conditions or clouds of vapour dust such as came from Krakatoa, may be carried in these high currents around the globe perhaps several times before being dissipated.

The average eastward movement of the west wind at 3 km. above Germany is 10.7 m. per sec. or 1° of longitude (at 45° latitude) in 42.4 minutes, or such as to describe the whole circumference of this small circle in 10-3 days. At the equator above the calm belt the velocity westward or the east wind as given by Krakatoa volcanic-dust phenomena was 34.5 m. per sec., or 30° of a great circle daily, or almost the equator in 1°, while its poleward movement was only 1° per day or 1.7 km. per second. The average motion of the storm centres moving westward in northern tropical and equatorial regions but eastward in the north temperate zone, is at the rate of one circum-ference or a small circle at latitude 45° in 19 days. Observations of the cloud movements gave Professor Bigelow the following results for the United States:

Evidently, therefore, the great west wind (that James H. Coffin deduced from his work on the winds of the northern hemisphere and that William Ferrel deduced from his theoretical studies) represents with its gentle movement poleward a factor of fundamental importance. We must consider all our meteorological phenomena except at the equator as existing beneath and controlled, if not
caused, by this general deep swift upper current of air that began as an ascending east wind above the calm equatorial air but quickly overflows the high wind settling down to the sea-level in the temperate and polar regions as great areas of high pressure and dry clear cool weather containing air on its return passage to the equator. The result is that the equatorial air moves north and south and mixes with the upper currents of heat and moisture. The west wind in the lower atmosphere moves south and rises the warm equatorial wind flows in beneath it, but when it descends we have blizzards and dry clear weather. It is a covering for the lower strata of air, flows over them in standing waves and sends down billows, and receives daily ascensions from below and gives out corresponding descents to the lower strata, by a process of overturning such as has been studied by Dr. W. H. Bigelow and Mr. Markgraf.

At the fifth conference of the International Committee on Scientific Aeronautics (Milan, October 1906) Ryklutech presented the results of kite-work during 1904 and 1905 at Pavlovsk, near St. Petersburg, from which we select the results for these two years given in table at foot of page 270.

Many inversions occur during January below 1000 metres. The decrease is more rapid in summer than in winter and in clear weather than in cloudy, but of course these observations did not extend above the upper level of the cumulus cloud layer. A general survey of the existing state of knowledge of the upper atmosphere is given in the Report of the British Association for 1899.

Distribution of Aqueous Vapour.—The distribution of aqueous vapour is best shown by lines of equal dew-point or vapour tension, though for some purposes lines of equal relative humidity are convenient. The dew-point lines are not usually shown on charts partly because the lines of vapour pressure are approximately parallel to the lines of mean temperature of the air, and partly because the observations are of very unequal accuracy in different portions of the globe. General ideas we may consider as agreeing with the dew-point line for dew-points a few degrees lower than the temperature of the air. The distribution of moisture is irregular both in a horizontal and in a vertical direction; and in the latter, the gradual increase of density with increase of altitude, the familiar lines of isentrope, are modified by the temperature variations. When the air temperature falls off rapidly with increase of altitude, the isentropes are curved upward at the lower altitudes, and at the medium and high latitudes the isothermal lines are curved upward at all altitudes. At middle and low latitudes, the isentropes are curved downward at all altitudes. On charts of the world we may draw lines based on actual observations to represent equal degrees of relative humidity, or equal dew-points and vapour pressures; but as regards the distribution of moisture in the atmosphere, the altitudes to which isopleths of the same humidity are continued, by the approximate formula, \( s = \log e_k - h/10001.1 \). Of course these relations can only represent average or normal conditions, which may be departed from very widely at any moment, but they have, however, been found to agree remarkably with all observations which have as yet been published. The average results are given in the following table, which is abbreviated from one published by Hann, but with the addition of the work done by the Weather Bureau of the United States, as reduced by Dr. Bigelow in 1899. The vapour constituent of the atmosphere is not distributed according to the law of gaseous diffusion, but, like temperature and the pressure, it being heterogeneous, is regulated by laws prescribed by the winds and currents, namely—convection.

Dimination of the Relative Vapour Pressure with Altitude.

Note.—The vapour pressure at any altitude is supposed to be expressed as a fraction of that observed at the ground. When the altitudes are given in ft. Hann's formula becomes \( \log e/\alpha = h/29359 \). From 78 high balloon voyages in Germany in 1887—1890, Suring derived the average vapour pressure in millimetres as follows:

Dimination of Pressure of Aqueous Vapour in the Free Air.

The first line of the table at foot of this page (see Wissenschaftliche Lufthoheiten, Bd. III., and Hann, Lehrbuch, 1906, p. 169). The observations were made during the summer and the first line of the table at foot of this page at about 1.20, Berlin time. Suring's figures result from the use of Assmann's ventilated psychrometer and are therefore very reliable.

The vapour pressure in mm. in free air over Europe is best given by Suring's formula:

\[ \log e_s = \log e_h - \frac{h}{0.17} \]

where the altitude is to be expressed in kilometres. From this formula we derive the "specific moisture" or the mass of vapour contained in a kilogram of moist air as given in the following table whose numbers do not appreciably differ from the "mixing ratio" or quantity of moisture associated with a kilogram of dry air. The relative humidities vary irregularly depending on convection currents, but in clear weather when descenting currents prevail they have been observed in America and over Berlin as shown in the third and fourth columns of the following table:

The total amount of vapour in the atmosphere, according to Hann's formula, is between one-fourth and one-fifth of the amount represented by Bigelow's. The following table taken from an article by Cleveland Abbe in the Smithsonian Report for 1888, p. 410—

A heavy rainfall results from the precipitation of only a small percentage of the water contained in the fresh supplies of atmosphere, but it could only affect the barometer throughout the equatorial regions by 2.8—3.6 inches, or about two-tenths of an inch, while at the polar regions the diminution would be much less than one-tenth. Evidently, therefore, it is idle to argue that the fall of precipitations in an extensive storm is to be considered as the simple result of the condensation of the vapour into rain.

Barometric Pressure.—The horizontal distribution of barometric pressure over the earth is shown by the isobars, or lines of equal pressure at sea-level; it can also be expressed by a system of complex spherical harmonics. As the indications of the meridional isobaric line must vary with the variation of apparent gravity, namely, whereas those of the aneroid barometer do not, it has been agreed by the International Meteorological Conventions that for scientific purposes all atmospheric pressures, when expressed as barometric figures, must be referred to one standard value of gravity, namely, its value at sea-level and at 45° of latitude. In this locality its value is such as to give in one second an acceleration of 980.6 centimetres, or 32.1 English ft., per second. The effect of the variation of apparent gravity with latitude is therefore to make the meridional barometer reading too high, between 25° and 45°, and too low, between 45° and the pole. The gravity-correction to be applied to any meridional barometric-reading at or near sea-level, in order to get the atmospheric pressure in
of standard units, should be given on the edge of a meteorological chart, unless the isobars shown thereon already contain this correction. The barometric pressure at sea-level is by no means uniform over the earth's surface, and daily weather charts show very great fluctuations in this respect, the lowest pressures being recorded in the regions where the highest temperatures are often recorded by weather. But even the normal average charts show high pressures over the continents in the winter and low pressures over the oceans, these conditions being reversed in the summer. Reichenbach (Ann. Phys., 1853) first demonstrated that the average pressure in the neighbourhood of the equator is slightly less than under either tropic, and that there is a still more remarkable diminution in the pressure at the equator towards the poles. The poleward movement of these variations of pressure with latitude was subsequently worked out very precisely by Ferrel, and forms the basis of his explanation of the general circulation of the atmosphere. Ferrel showed that the atmosphere is not only a partial vacuum but also a fluid, and the influence of the land upon the barometer may be seen in the series of monthly charts for the whole globe, compiled by Buchan and published by the Royal Society of Edinburgh in 1868, as well as Buchan's later and more perfect publication "Challenger." The attempts to explain the atmospheric phenomena by the methods of reduction to sea-level; indeed, if the data of the lower stations are reduced up to the level of 10,000 or 15,000 ft., we sometimes find conditions precisely opposite to those of the actual station. These non zero changes are intimately connected as cause and effect with the annual changes of temperature, moisture and wind; it is quite erroneous to say that the observed charted pressures control the winds; these must be deduced from the forces bounding the air, and the rate of change of pressure. The resistance and rotation of the earth's surface, such that the true relation between these factors is a complex but fundamental problem in the mechanics of the atmosphere.

The vertical distribution of pressure as deduced from observation shows a rate of diminution with increasing altitude very closely but not entirely accordant with the laws of static equilibrium, as first pointed out by C. P. Held. The departures from this law of static equilibrium are sufficient to show that, if our atmosphere is really in a state of equilibrium, it must be a matter of dynamics and experience. The general law is reversed, the pressure decreasing as the altitude increases. The cause of this is the difference between the air above and the air we use on the earth's surface. The pressure and the temperature of the superincumbent atmosphere, are shown in the accompanying diagram (fig. 1), which is taken from a memoir on the equations of motion by Joseph Cottier, published in the U.S. Monthly Weather Review for July 1897. The diminution of pressure with altitude, as shown in this diagram for average conditions, but not for the temporary conditions that continually occur, follows a logarithmic law, and is explicable as the result of the heat absorbed by and radiated from moist or hazy or dry air. In 1890, Abbe showed that a very moderate rate of radiation from the atmosphere suffices to explain the coolness of slowly descending air. The absorption by the atmosphere of radiation from the earth, or the balance between warming by absorption and cooling by radiation, is the basis of the arguments of A. Apsenmus (Atmosphere, in his 1899, and E. Godet, Rev. Roy. Soc., 1908, lxxii., 45 A.), explaining the existence of the "thermal layer."

The direct evaluation of this radiation and absorption has been attempted by several people, the most genuine of the individual laws (6-9) is adopted by Gold as closely representing nature, whence it follows that (1) the adiabatic rate of cooling in convection currents must cease at a height corresponding to the barometric pressure at sea-level; (2) an isothermal layer must exist at the level where the absorption of solar radiations equals that of the terrestrial and atmospheric radiations; (3) within this thermal layer convection is difficult or impossible; (4) the rate of temperature decrease must depend essentially on radiation and is less than that needed for convective equilibrium; (5) below this level the atmosphere radiates the absorption and vertical currents can only be kept up by the evaporated moisture and vaporous vortices from the earth's surface to the adjacent layer of air.

Limit of the Atmosphere.—The limiting height of the atmosphere must be considered when the observation of the invisible moisture within the circle of invisible moisture is important. The surface of the cloud is so absorbed and reflected that, on the one hand, scarcely any penetrates to the ground beneath, while on the other hand the upper surface of the cloud becomes unduly heated. Even if the upper surface of the cloud is not entirely reversed, it may be continually removed from below, and, moreover, the evaporating cloud working in the air renders it very much lighter specifically than it would otherwise be. Hence the upper surface of the cloud reflects the light from the surface of the ground and of the ocean; the air in contact with it acquires a higher temperature and those conditions of the ground and air beneath it remain the same as they would be in sunshine. The average cloudiness over the globe is therefore intimately related to the density and circulation of the atmosphere: it was first charted in general terms by C. P. Held in 1860, and more accurately by the U.S. Naval Observatory in 1886. The main differences in the atmosphere may be seen by the average cloudiness over the globe, charts for the whole globe, compiled by Buchan and published by the Royal Society of Edinburgh in 1868, as well as Buchan's later and more perfect publication "Challenger." The attempts to explain the atmospheric phenomena by the methods of reduction to sea-level; indeed, if the data of the lower stations are reduced up to the level of 10,000 or 15,000 ft., we sometimes find conditions precisely opposite to those of the actual station. These non zero changes are intimately connected as cause and effect with the annual changes of temperature, moisture and wind; it is quite erroneous to say that the observed charted pressures control the winds; these must be deduced from the forces bounding the air, and the rate of change of pressure. The resistance and rotation of the earth's surface, such that the true relation between these factors is a complex but fundamental problem in the mechanics of the atmosphere.

The movements of the upper clouds are more rapid in winter than in summer at these northern stations, but among the median and lower clouds a retardation takes place apparently due to the ascending currents that form rain and snow. Above 8000 metres at Upsala the average velocity in winter exceeds 30 metres per second, whereas in summer it is 20; at Toronto and Blue Hill the absolute velocities are lower, but by the same ratio. In the United States the maximum velocities from the west attain 100 metres per second and over 80 or 70 metres per second are not rare, but in Europe the corresponding figures are 70, 60, 50. (See also CLOUDS.)

II.—Meteorological Apparatus and Methods

The observational basis of meteorology is the frequent and, if possible, continuous record of the temperature, moisture and barometric pressure at different altitudes in the free atmosphere, the direction and velocity of the wind, the rain and snow-fall, and the amount of cloud. For Europe these data have been furnished with more or less accuracy and continuity by thousands of observers ever since 1653, when Ferdinand II., grand duke of Tuscany, organized a system of daily observations in Italy under the general supervision of Luigi Antonini. During the 19th century great efforts were made to obtain equally full records from all parts of the land and ocean, and thousands of navigators were added to the great corps of observers. Other matters have also been investigated, the most important being the intensity of radiation from the earth at night-time and from the sun by day-time, the optical phenomena of the sky, the amount of dust in the air, the electrical condition and the chemical constitution of the atmosphere. Although all the instruments used belong to the category of physical apparatus, yet certain points must be considered as peculiar to their use in connection with meteorology.

Thermometer.—In using the thermometer to determine the temperature of the free air it is necessary to consider not merely its intrinsic accuracy as compared with the standard gas thermometer of the International Bureau of Weights and Measures at Paris, but especially its sluggishness, the influence of noxious radiations, the change of its zero point with time, and the influence of atmospheric pressure.

[1] We have here inserted the Washington data as interpolated from the figures given by Hanh, Lehrbuch, 1906, p. 282.

Sensitivity.—The thermometer indicates the temperature of the outside surface of its own bulb only when the whole mass of the instrument has a uniform temperature. Assuming that by appropriate convexion of the surface of the bulb, the instrument is in contact at the temperature of the air, we have still to remember that ordinarily itself is perpetually changing both in rapid oscillations of many degrees and in daily periods of many degrees, while the thermometer, on account of its own mass, is much more sluggish, always lagging behind the changes in the temperature of its own surface. On the other hand, radiant heat passes easily through the air and reaches the thermometer, and raises its temperature quite independently of the influence of the air whose temperature we wish to measure. The internal sluggishness or the sensitivity of the thermometer is usually different for rising and for falling temperatures, and is measured by the coefficient which is determined experimentally for each instrument by observing the rate at which its indications change when it is plunged into a well-stirred bath of water whose temperature is either higher or lower than the tube. This coefficient indicates the rate per minute at which the readings change when the temperature of the surface of the bulb is one degree warmer or colder than the temperature of the bath. Such coefficients usually vary between 4th and 12th of a degree centigrade for sluggish thermometers, and one or two degrees for very sensitive thermometers. Suppose, for instance, that the coefficient is one-half degree, then when the rate of change in the temperature of the air is one degree per minute this is exactly the same as a rate of rise of 0.5° of temperature which the thermometer itself undergoes when its own temperature is two degrees different from that of the air; consequently the thermometer will lag behind the air to that extent and by the corresponding amount of time, assuming that the air itself flows fast enough to keep the surface of the bulb at the same temperature as the air temperature ceases to rise or fall, and begins to change at the same rate and for each degree correction, the thermometer will fail to record the true maximum or minimum temperature by an appreciable error depending upon the rapidity of the change, and will follow the new temperature change with the same lag. For example, in the case just quoted, if a rising temperature suddenly changes to a falling temperature, the error of the thermometer at the maximum temperature will be two degrees, and yet the thermometer may be absolutely correct compared with the standard when it is allowed five or ten minutes' time to overcome the sluggishness. It is very difficult to obtain a perfectly dry bulb, and the absorbtion of water into a roughened surface of lamp-black radiates and absorbs perfectly; one of chalk powder does nearly as well; glass much more imperfectly; while a polished silver surface reflects with ease, but radiates and absorbs with the greatest difficulty. Fourier proposed to use two thermometers side by side, one of plain glass and the other of blackened glass; the difference of these would indicate the effect of radiation at any moment; but instead of plain glass he should have used silvered glass. His method is quite independently devised and used by Abbe in 1865 and 1866 at Pouikova, where the thermometers were placed within a very light thin silvery paper enclosed in a tin tube. The difference between the black and the silvered thermometers should be gathered side by side inside the thermometer shelters (see Bulletin of the Philosophical Society of Washington for 1853). Various forms of these apparatus have been devised and used by Glashier, Kupper, Stevenson, Stowe, Dove, Renou, Joseph Henry and others, in all of which the wind is supposed to blow freely through the screens, while the latter cut off the greater part of the sun's rays. In the evening the air is greatly cooled by the night. The Italian physician Belli first proposed a special method for ventilation of the atmosphere and the fresh air was made to flow rapidly over the thermometer. Even before his day de Saussure, Esly, Arago and Bravais whipped the thermometer rapidly either by a small whirling machine, or by attaching it to a small wheel which was set in motion by a piece of silk or string tied about the bulb. When the wind is used as a means of making it flow rapidly over the thermometer. Even before his day de Saussure, Esly, Arago and Bravais whipped the thermometer rapidly either by a small whirling machine, or by attaching it to a small wheel which was set in motion by a piece of silk or string tied about the bulb. When the wind is used as a means of making it flow rapidly over the thermometer.
in a fixed louvre shelter, but by means of a ventilating apparatus drew currents of fresh air from below into the shelter, where they circulated rapidly and passed out. In Germany, since 1885, Dr. Assmann has developed the so-called Assmann instrument, in which the dry-bulb thermometer is placed within a double shelter of thin metallic tubing, and the air is drawn in rapidly by means of a small ventilating fan. In the observations made on the Western Coast of Africa, the dry- and wet-bulb thermometers were enclosed within bamboo tubes and rapidly whirled. The inside of the wet-bulb tube was kept wet, so that it was cooled appreciably by evaporation compared to the dry bulb. In the system of exposure adopted by the U.S. Weather Bureau the dry and wet bulbs are whirled by a special apparatus fixed within the locomotive, and the thermometer is sufficiently cooled if it is carried on a rope suspended a few inches above the ground or building to ensure free exposure to the wind. In using the whirling and ventilating methods it is customary to take a running average of reading one minute treatment of the bulb has received as to temperature. Owing to the slow adjustment of the molecules of the glass bulb to the state of stable equilibrium, their relations among themselves are disturbed whenever they are rapidly treated. A second effect is that the liquid is temporarily depressed to an amount nearly proportional to the heating. The normal method of treatment consists in first determining the zero of the thermometer, and, if necessary, to raise the freezing-point. If this method is uniformly followed the two fiducial points will stay in permanent relation to each other. A thermometer that has been used for many years by a faithful meteorological observer has almost inevitably been going through a steady series of changes; in the course of ten years its freezing-point may have risen by 2° or 3° F., and, moreover, it changes by a tenths of a degree between summer and winter. The only way completely to eliminate this source of error from meteorological work is to discard the mercurial thermometer altogether; but instead of adopting that course, the use is generally recommended of the hygroscopic instruments which are specific for their purpose, and, which heating and cooling have comparatively little influence. Any argument as to secular changes in the temperature of the atmosphere is likely to be greatly weakened by the unknown influence of the observer's technique, as well as the changes in the method of exposure and in the hours of observation.

Barometer.—The barometer (q.v.) indicates the elastic pressure prevailing in gas or liquid at the surface of the mercury in the open tube or eisern, provided that the fluid at that point is in a state of quiet relative to the mercury.

Any motion of the air will have an influence upon the reading quite independently of the prevailing elastic pressure. The rise of the barometer within a mass of gas at any point is the summation of the effects due to the motions of the myriad molecules of the gas at that point; it consists of kinetic energy of the molecules striking again and again on the walls of the vessel, and the sides of the enclosure, which in this case is the surface of the mercury in the eisern of the instrument. If the barometer moves with respect to the general mass of the gas there will be a change in the residual pressure by whatever the deviation may be from the general mass of the free gas, and a barometer giving correctly the pressure of the air rest at rest within a room will give a different reading. If a barometer is set in rapid motion so that the air strikes violently against it. If the barometer with the air it will indicate the elastic pressure within the air. When the wind blows against an obstacle the air pressure is increased above that at the other side of the obstacle; for example, the wind at the top of a chimney is stronger than that at the bottom. It is thus obvious that in determining the pressure within the free atmosphere the exposure of the barometer must be carefully considered. The simplest way of gaining a general idea of the pressure of a given wind is to raise the elastic pressure within a room whose windows are open to the wind. The effect of the wind is to lower the pressure if the window faces to the leeward. The influence of the draught up chimney, produced by the wind blowing over the roof, is not so much felt within the building. The maximum effect of the wind in raising the pressure is given by the formula, 

\[ P - P_0 = -0.0000383 X V^2, \]

where the pressure is given in inches and the velocity in miles per hour. This amounts to about one-tenth of an inch in a 50-m. wind, and to nearly four-tenths in a 100-m. wind. The effect of a diminished pressure at the top of a chimney is usually less than this amount. This alteration in pressure, due to the local effect of the wind, does not belong to the free atmosphere but to the method of exposure of the instrument, and was observed as early as 1773 by Dr. Price, who is described by Abbe in 1852: it is a very different matter from the general diminution of pressure in the atmosphere produced by the movement of the wind with which it is associated. The latter is an atmospheric phenomenon, independent of instruments and locality, which in hurricanes and tornadoes may affect several inches of the mercurial column. It is, however, quite possible, in some localities, to find to the point records of the pressure due to hurricanes in newspapers in the local newspaper. The changes in the condition of the surfaces of the glass of the instrument, and not exposure to the open air. The international comparisons of barometers show that discrepancies exist between the best normals or standards, and that ordinary barometers must be corrected for their latitude. The barometer is used to determine the barometric pressure at any time and in the conditions of the localities and the temperatures and pressures for which they are to be used.

Anemometer.—The wind is measured either by means of its pressure against any obstacle or by revolving apparatus that gives some idea of the velocity of its movement. The pressure is supposed to interest the engineer and navigator, but the velocity is the fundamental quantity, and is determined by the method of measurement the pressure waves. The pressure of the wind varies with the nature of the obstacle, the method of exposure, the density of the air, and even the mass of rain carried along with it.

Pressure anemometers date from the pendulous table devised by Sir Christopher Wren about 1667, and such pressure plates continue to be used in an improved form by Russian observers. Non-pressure pressure generated this instrument by the wind, and the modern type of instrument is to be found in all weather stations. The windmill anemometers devised by Schober and Woltemann were modified by Combes and Casella so as to make an exceedingly delicate instrument for laboratory use; another modification of this type is extensively used by French observers. In the early part of the 19th century Edgeworth devised and Robinson perfected a windmill system in which hemispherical cups revolved around a vertical axis, and these have come into general use in both Europe and the United States. The anemometer consists of a ratio between the velocity of the wind and the rotations of the Robinson anemometer. The factor 3 is usually adopted and corrections from the device have been made to allow for the ratio between the velocity of the wind and the rotation of the Robinson anemometer. The factor 3 is usually adopted and corrections from the device have been made to allow for the ratio between the velocity of the wind and the speed of the wind, but especially with the steadiness or gustiness of the wind. The factor must always be determined experimentally for each specific type of instrument; in most instruments in actual use the factor for steady wind varies between 2.4 and 2.8. When the wind is gusty the moment of inertia of the moving parts of the instrument necessitates an appropriate correction; thus, when the gust is at its height the revolving parts receive an impetus that lasts after the gust has gone down, so that the actual velocity of the cups is too high. For this reason, also, comparisons and studies of anemometers made in the open air have given natural wind speeds by combining the average natural and gusty winds at Washington, D.C., and on Mount Washington, N.H., and the small type of Robinson's anemometer used by the U.S. Weather Bureau Service, Professor C. F. Marvin deduced the table (see p. 272) for reduction from recorded to true velocity. This table involves the moment of inertia of the revolving parts of the instrument and the gustiness of the winds at Washington, and the effects of wind differing from these, and other types of instruments or winds, for which special studies must be made.

About 1842 a committee of the American Academy of Arts and Sciences experimentally determined, for a large variety of chimney caps, or ovens, or hoods, the amount of suction that produces the draught up a chimney, and shortly afterwards a similar committee published similar investigations. The results of these investigations showed that the open end of the chimney, acting as an obstacle in the wind, is covered by a layer of air moving more rapidly than the free air at a little distance, and that the height between this layer and the aperture of the chimney there is a space
within which barometric pressure is less than in the neighbouring free air. The draught up the chimney is due to the pressure of the air at the lower end or fireplace pushing up the flue into this region of less pressure, and is in addition to the buoyancy of the heated air within the flue. From such experiments as these there has been developed the vertical suction-tube anemometer, as devised by Fletcher in 1867, re-invented by Hagemann in 1876, and introduced into England by Dines. In his Meteorological Apparatus Marvin’s Table for the Reduction of Velocities, given by the small-sized Robinson’s Anemometer in gusty states.

Indicated Velocity. True Velocity.

and Methods (Washington, 1887) Abbe gives the theory of this class of anemometers,会给 additional formulas. Two vertical tubes, whose apertures are respectively directed to the windward and the leeward, and within which are two independent barometers, give the means of determining the barometric pressure upon the windward side, thus the wind pressure respectively, so that both the velocity of the wind and the true barometric pressure can be determined. If instead of a simple opening at the top of the tube we place there horizontally the cone and Venturi tube, we obtain a maximum wind effect, which gives an accurate measure of the wind velocity, and is the form recommended by Bourdon as an improvement on that of Arson. In all anemometers of this class the air in the movable part is reduced to a minimum, and the measurement of rapid changes in velocity and of the maximum intensity of gusts becomes feasible. On the other hand, these researches have shown how to expose a barometer so that it shall be free from the dynamic or air effect even when it has only to be placed within a room or box that is connected with the free air by a tube that ends in a pair of parallel plane plates. When the wind blows past the end of this tube it flows between these plates in steady linear motion, and can produce no disturbance of pressure at the mouth of the tube if the plates are at a suitable distance apart. This condition of stable flow, as conceived by Venturi and described by Thomson (Lord Kelvin) (see Phil. Mag., Sept., 1877). Such a pair of small circular plates can easily be applied to a tube screwed into the air-hole at the back of any aneroid barometer, and thus render the instrument independent of the influence of the wind.

As to the exposure of the anemometer, no uniform rules have as yet been adopted. Since the wind is subject to exceedingly great disturbances by the obstacles near the place of observation, it is necessary to estimate the force of the wind by noticing all that goes on over a large region about him has some advantage over an instrument that can only record the wind prevailing at one spot. The practice of the U.S. Weather Bureau has been to insist upon the perfectly free exposure of all anemometers as high as can possibly be attained above buildings, trees and hills; but, of course, in such cases they give records for an elevated point and not for the ground. They are therefore not precisely appropriate for use in local climatological studies, but are those needed for general dynamic meteorology, and proper for comparison with the isobars and the movements of the clouds shown on the daily weather map.

Meteorology

Hygrometer.—Moisture floats in the atmosphere either as invisible vapour or as visible haze, mist and cloud. The presence of the latter generally assures us that the earth is wetter than the atmosphere. The relative humidity in any air mass can be determined by the Schawkhofer or Svensson hygrometer, or it may be ascertained by warming a definite portion of the air and fog and measuring the tension of the vapour by Edelmann’s apparatus. Both these methods, however, are in practice open to many sources of error. If only invisible aqueous vapour is present we may determine its amount by several methods: (a) the chemical method, by absorbing and weighing it; (b) the dew-point method, by cooling the air down to the temperature where condensation begins; (c) Edelmann’s method, by absorbing the moisture chemically and measuring the change in vapour tension; (d) by adding vapour until the air is saturated, and measuring either the increased tension or the quantity of vaporization; (e) the psychrometric method, by determining the temperature of evaporation.

The wet-bulb thermometer, which is the essential feature of the last-named apparatus, was used by Fahrenheit in 1776, but merely as giving an index of the dryness of the air. The correct theory of its action was elaborated by many early investigators: Ivory, 1822; August, 1823; Apjohn, 1834; Bell, 1838; Regnault, 1842; and finally by Cambridge and Blyth, in 1853. In 1776, it was made in our knowledge of the subject, and it was supposed that the psychrometer was necessarily crude and unsatisfactory; but the modern form has become an instrument of much greater precision, probably quite one of the truly accurate for determining atmospheric moisture. In order to secure this accuracy the two bulbs must be of the same size, tables by Bjerkland for temperatures below freezing (Condon and 1907) represent the present condition of our knowledge of this subject. Glasser deduced empirically from a large mass of observations certain factors for computing the dew-point, but these do not repel the accuracy that can be attained with the wet-bulb psychrometer, nor are they thoroughly satisfactory when used with Regnault’s tables and the stationary psychrometer. Especially should there be a case be disposed when the wet bulb, which is only below the dry bulb and the atmosphere correspondingly dry. For occasional use at stations, and especially for daily use by travellers and explorers, nothing can exceed the convenience and accuracy of the sling psychrometer, especially if the bulb are protected from radiation by a slight covering of non-conducting material, or even metal, as was done by Craig in 1866–1868 for the stations of the U.S. Army Surgeon-General. The hair hygrometer gives directly the relative humidity or the ratio between the moisture in the air and that which it would contain if saturated. The very best forms perform very well for a time, and are strongly recommended by Perrett for balloons and kites. They are standardized by parision with the ventilated psychrometer, which itself must be dependent on the standard dew-point apparatus.

Rain and Snow Gauge.—The simple instrument for catching and measuring the quantity of rain, snow or hail that falls on a definite horizontal or inclined surface is essentially a cylinder and the measuring apparatus. The receiving mouth of the cylinder is usually terminated by a cone or funnel, so that the water running down through the funnel and stored in the cylinder is protected from evaporation or other loss. The cylinder is firmly attached to the ground or building, so that the mouth is held permanently at a definite altitude.

The sources of error in its use are the spattering into it from the ground or neighboring objects, the loss due to wind blowing against the side of the cylinder it produces eddies and currents that carry away drops that would otherwise fall into the mouth, and even carries out of the cylinder drops that have fallen into it from a previous rainfall. The gauge catch and measure too little rainfall. The deficit increases with the strength of the wind and the smallness or lightness of the raindrops and snowflakes. If we assume that the correct weight is given by a gauge situated in the air over the ground and is surrounded by a trench wide enough to prevent any spatter, then, on the average of many years and numerous observations, with ordinary instruments, the average deviation from the average character of the rain in that region and the average strength of the attending winds, the deficit of rain caught by a rain-gauge whose mouth is 1 metre above the ground is 6% of the amount; if its mouth is 5 metres above it will be 33%. This deficit increases as the gauges are higher above the ground in proportion approximately to the square root of the altitude, provided that they are fully exposed to the increase of wind that prevails at those altitudes. It is evident that even for
METEOROLOGY

Altitudes of 5 or 10 ft. the records become appreciably discrepant from those obtained at the surface of the ground. The following table shows in the last column the observed ratio between the catches of gauges at various altitudes and those of the respective standards at the level of the ground. Unfortunately, there are no records of the force of the wind to go with these measurements; but we know that in general, and on the average of many years, correspondingly high barometric pressures that produce the velocity of the wind increases very nearly as the square root of the altitude. Although this deficit with increasing altitude has been fully recognized for a century, yet no effort has been made until recent years to make a proper correction or to eliminate this influence of the wind at the mouth of the gauge. Professor Joseph Henry, about 1850, recommended to the observers of the Smithsonian Institution the use of the "pit-gauge." About 1888 he recommended a so-called shielded gauge, namely—a simple cylindrical gauge 2 in. in diameter, having a wide horizontal sheet of metal like the rim of an inverted hat soldered to it. This would undoubtedly diminish the obnoxious differences in the results of the very numerous comparative observations that have been made in connection with the "pit-gauge," and with the "protected gauge" devised by Boernstein, who sought to prevent injurious eddies about the mouth of the gauge by erecting around it at a distance of 2 or 3 ft. an open fence of wire, while at its top he raised slightly higher than the mouth of the gauge. The boards or slats are not close together, but apparently afford as good a protection as the shield of Professor Nipher, and give good results with both snow and rain.

</table>

In general it is now conceded by several high authorities that the measured rainfall must be corrected for the influence of the wind at the gauge, if the latter is not annulled by Nipher's or Boernstein's methods. A practicable method of measuring and allowing for the influence of the wind, without introducing any very hazardous hypothesis, was explained by Abbe in 1888 (see Symons's Meteorology and Methods of 1899). This method consists in estimating the influence of the wind, like that of the rainfall, is nearly in proportion to the square root of the altitude, the difference between the records for two different altitudes may be the basis of a correction which gives the correction to be applied to the record of the lower gauge, in order to obtain the rainfall that would have been caught if there were no wind. It is only when the catch of the gauge has been properly corrected for the effect of the wind that we have obtained numbers that are proper to serve for the purpose of determining the variation of the rainfall with altitude and locality, the influence of forests and the periodical changes of climate. Methods of measuring dew and the estimation of the amount of water left after evaporation are subjects which still remain to be devised; each of these has its thermodynamic importance and must eventually enter into our calculations.

It is now common to consider that the rain-gauge cannot be properly used on ships at sea, owing to the rolling and pitching of the vessel and the interference of masts and rigging; but if gauges are mounted on gimbals, the correction for their records will be of great importance. The experimental work of this sort was done by Mohn, and afterwards in 1882 by Professor Frank Waldo; but the most extensive inquiry has been made by Mr. Smith (B. contribution to the American Journal of Science, 1896, vol. xiv.), which satisfactorily demonstrates the practicability and importance of the marine rain-gauge.

**Evaporometer.**—The moisture in the atmosphere comes from the surface of the earth or ocean by evaporation, a process which goes on continually, replacing the moisture there precipitated as rain, hail, snow, and dew, and maintaining the total quantity of the moisture in the atmosphere at a very uniform figure. The rate of evaporation depends upon the temperature, the dryness, and the velocity of the wind. It is not so important to meteorologists to know how the moisture comes from as to know its amount in the atmosphere, and in fact no method has yet been devised for determining how much moisture is given up by any specific portion of the earth, ocean, or forest. Our evaporometers measure the quantity of moisture given off by a specific surface of water, but it is so difficult to measure this water under natural conditions that it remains in nature that no conclusions can be safely deduced as to the actual evaporation from natural surfaces. The proper meteorological use of these evaporometers is, as integrating hygrometers, to give the average humidity of the air, the psychrometer giving the conditions prevailing at any moment.

Among the many forms of evaporometer the most convenient is that devised by Piche, which may be so constructed as to be exceedingly accurate. The Piche evaporometer consists essentially of a glass tube whose upper end is closed hermetically, whereas the lower end is covered by a horizontal disk of bibulous paper, which is kept wet by absorption from the water in the tube. As the water evaporates its descent in the tube is observed, whereas the volume evaporated in a unit of time becomes known. So long as the paper remains clean, and the water is pure, the records of the paper reflect the amount and evaporation on the surface, the dryness of the air, and the velocity of the wind. Careful comparisons between the Piche and the various forms of absolute evaporimeters were made by Professer Trowbridge and others, and the results were published in the *U.S. Monthly Weather Review* for September 1898, pp. 235–239. By placing the Piche apparatus upon a large whirling machine he was able to show the effect of this water of the amount of evaporation, which enabled him to explain the great differences recorded by the apparatus established at eighteen Weather Bureau stations; based upon these results, he prepared a table of relative evaporation within thermometer shelters at all stations. The actual evaporation from ground and water in the sunshine may run parallel to these, but cannot be accurately computed. It is probable that Professor Trowbridge's computations are smaller than the evaporation from shallow bodies of water in the sunshine, but larger than for deep bodies, like the great lakes, and for running rivers. Recent elaborate studies of evaporation have been undertaken in Egypt and the other countries under the same latitude, and in southern California. Here the Colorado river, having broken through its bends, emptied itself into a great natural depression and formed the so-called "Salton Sea," about 50 m. long, 20 wide and 100 ft. deep, before it could be brought under artificial control. This sea is now isolated, and will, it is hoped, dry up in eight or ten years. Meanwhile the U.S. Weather Bureau has established a large number of stations for the study of evaporation, and has begun the study not only of the relation between evaporation, wind and temperature, but of the eventual disposition of this evaporation throughout the atmosphere in the neighbourhood of the earth. The U.S. Monthly Weather Review, 1897–1907, also as the elaborate bibliography of evaporation in the same volume). Although the evaporation of the earth's surface is scarcely measurable to our hygrometric apparatus, yet it is said to be in the development and ripening and drying of the dates raised on the U.S. government experimental "date farm" a few miles north-east of the Salton Sea.
Nephoscope.—The direction and apparent velocity of the motion of a cloud are best observed by means of the nephoscope, which has now become a necessary item in the outfit of any first-class meteorological station. Among the various forms of this instrument are the nephoscope of Fornioni, the marine nephoscope of Fineman, the simple mirror with attachments used by Clayton, the cloud camera of Vettin, and the altazimuths of Mohl and Lettry. The most perfect form for use on land is that devised by Professor Marvin in 1896 for the U.S. Weather Bureau stations (see fig. 2); while the most convenient for use at sea is that devised and used in 1889 by Professor Abbe on the cruise of the U.S. ship "Pensacola" to the west coast of Africa, but first described in the report of the International Meteorological Congress held at Chicago in August 1893.

The construction of this instrument is shown in figs. 3, 4, 5. In using it the observer looks down upon a horizontal mirror and observes the reflection of the cloud. By moving his eye he brings any cloudy point into coincidence with the reflection of a small fixed spherical knob K above the mirror, and keeps the image of the knob and the cloud coincident as they pass from the centre of the mirror to its edge. This line of motion shows the azimuth of the horizontal component of the cloud's motion. The course of the vessel is shown by the compass card and lubber line AP seen below the mirror. The apparent angular velocity of the cloud, as it would be if the cloud started from the zenith, is obtained by counting the seconds that elapse between its passage from the centre to the edge, or to a small circle inscribed within the edge. With Marvin's nephoscope two observers a short distance apart may easily determine the apparent altitude, and azimuth, and motion of any cloud whose true altitude and velocity may be computed. But when the observer uses Abbe's marine nephoscope on a vessel which is itself in motion he observes the resultant of his own motion and that of the cloud. If his vessel is under his control, so that he may change its course, velocity, or direction at will in this path, due to the motion of the vessel, the observation can easily determine the resultant for two different courses, and obtains data by which he is enabled to calculate the real altitude and velocity of the cloud in terms of its own velocity. As the marine nephoscope can be used on a wagon moving rapidly over a smooth road, or in a small boat on a smooth pond, as well as on a larger sea-going vessel, it becomes an instrument of universal application for cloud study. It is also equally convenient for observing the positions of auroras, halos, meteors, and other special phenomena. For the international work undertaken during the year 1898 the photographic camera established upon an alt-azimuth mounting, or the so-called photographometer, was especially developed (see apparatus photographs of the clouds are taken simultaneously at two or more stations, and in each case the centre of the photographic plate has its altitude and azimuth determined. From this center one can measure on the plate the additional angles required in order to fix the altitude and azimuth of any point that is photographed, and thus the dimensions of the whole visible cloud and its internal or differential motions can be determined, as well as its general motion. During the years 1896-1898 about twenty stations were occupied throughout the world for the purpose of determining accurately the altitudes and motions of every layer of cloud.

Sunshine Recorder.—The ordinary meteorological record specifies the proportion of sky that appears to be covered with cloud, or the so-called cloudiness, usually expressed in tenths. The observer generally confines his attention to that portion of the sky within sixty degrees of the zenith, and ignores the lower zone, since the clouds that are found therein are often at so great a distance from him that their record is not supposed to belong to his locality. As the cloudiness—or its reciprocal, the sunshine—is supposed to be the most important item in agricultural climatology, and is certainly very important for dynamic meteorology, it is usually considered desirable to obtain more complete records than are given by only one or two specified hours of observation. To this end apparatus for recording sunshine, or, rather, the effect of cloudiness, is widely adopted. At least three forms are worth describing as being extensively used.

The Jordan photographic sunshine recorder consists of a cylinder enclosing a sheet of sensitive paper; the sun's rays penetrate through a small aperture, and describe a path from sunrise to sunset, which appears on this sheet after it has been properly washed with the fixing solution. Any variation in width or hazy, is of course clearly shown, and gives at once the means of estimating what percentage of the day was clear and what cloudy. The modified form of the instrument was devised for a certain standard difference of temperature of about 5° F., such as would be produced by the sun shining through a very thin cloud. The record is made by an electric current on a revolving drum, and simply shows when during the day sunshine, or the absence of it, prevailed, or was prevented by cloudiness. D. T. Maring, in the U.S. Monthly Weather Review for 1897, described an ingenious combination of the thermocouple and the photographic register of cloudiness which is worthy of further development. It gives both the quantity of cloudiness and intensity of the sunshine on some arbitrary relative scale.

The intensity of the sunshine, as sometimes employed in general agricultural studies, is crudely shown by Viole's conjuge bulbs, which are thin copper balls about 3 in. in diameter, one of them being blackened on the outside and the other gilt. When exposed to the sunshine the difference in temperature of the two bulbs increases with the intensity of the sunshine, but as the difference is dependent to a considerable extent on the wind, the Viole bulbs have not found wide application. The Arago-Davy actinometer, or bright and black bulbs in vacuo, constitutes a decided improvement upon the Viole bulbs, in that the vacuous space surrounding the thermometers diminishes the effect of the wind. The physical thermocouple devised in the year 1896 by C. L. Pouillet of the University of Paris was further developed by Ferrel, and he was able to determine the coefficient of absorption of the earth's atmosphere and other data, thereby almost abolishing the wind's influence. When using it as contemplated by Arago and Davy and by Professor Ferrel, we read simply the stationary temperature attained by the bright and black thermometers at any moment, whereas the best modern actinometers are in an all-or-none condition, whether there is sunshine or not; and any appropriate apparatus so as to determine the total effect of the solar radiation in one minute, or some shorter unit of time; this method of using the Arago-Davy actinometer was earnestly recommended by Abbe in 1883, and in fact tried at that time; but the apparatus and records were unfortunately burned up. This so-called dynamic, as distinguished from the static, method was first applied by Pouillet in 1838 in using his pyrheliometer, which was then the only apparatus and method that gave appropriate measures of the radiant heat received from the sun. In order to improve upon Pouillet's work more delicate apparatus has been constructed, but the essential mechanical mechanism is the same. Mr. Arago also applied both Langley's bolometer and his own still more sensitive thermoelectric couple and balance method; Viole uses his absolute actinometer, consisting of a most delicate thermometer with poeheliometer and thermal scale, deeply immersed in the flow of water; while Crova, with a thermometer within an enclosure of uniform temperature, claims to have attained an accuracy of one part in a thousand. Many forms of the so-called absolute actinometer, and has shown the greater delicacy of his own apparatus, consisting of two thin plates alternately exposed to and shielded from sunshine, whose differences of temperature are extended by electric means.

As none of the absolute methods for determining the solar radiation in units of heat lend themselves to continuous registration, it is important to call attention to the possibility of the use of the mechanical method of Pouillet's apparatus to be that devised by Marchand, by the use of a device which he calls the Phot-antitupimeter. In this the action of the sunlight upon a solution of ferric-oxalate and chloride of iron liberates carbonic acid
gas, the amount of which can be measured either continuously or every hour; but in its present form the apparatus is affected by several serious sources of error.

FIG. 3.—Abbe's Marine Nephoscope. Horizontal Projection of Mirror.

The electric compensation pyrheliometer, as invented by Knut Angström (Ann. Phys., 1899), offers a simple method of determining accurately the quantity of radiant energy. He employs two blackened platinum surfaces, one of which receives the radiations to be measured, while the other is heated by an electric current. The difference of temperature between the two disks is determined by a thermocouple, and they are supposed to receive and lose the same amount of energy when their temperatures are the same. A Helmer.

FIG. 4.—Abbe's Marine Nephoscope. Horizontal Projection of Compass.

on the intensity of the solar radiation at two points, respectively, 360 and 3352 metres above sea-level, and determined the amount of heat absorbed by the intermediate atmosphere. An Angstrom of 1-1000 appears to be attainable, and this apparatus is now being widely used. The records of 1901-1905 have already given rise to the belief that there is a variation in our insolation that may eventually be traced back to the sun's atmosphere.

Meteorograph.—The numerous forms of apparatus designed to keep frequent or continuous register of the prevailing pressure, temperature, moisture, wind, rainfall, sunshine, evaporation, and other phenomena are instruments that belong peculiarly to meteorology as distinguished from laboratory physics. Such apparatus may be broadly divided into several classes according as the records are obtained by the help of photography, or electricity, or by direct mechanical action. The prevailing tendency at present is in favour of apparatus in which the work of the recording pen is done by a falling weight, whose action is timed and limited by the making and breaking of electric currents by the meteorological apparatus proper. The most serious defect in such instruments, even when kept in good working order, is a want of sensitiveness commensurate with the desired openness of scale. It is very important that a fraction of a minute of time should be as recognizable as one-tenth of a degree of temperature; one thousandth of an inch of baromeric pressure, and velocities of one hundred miles per hour, as well as rapid changes in all these elements, must be measurable. But instruments whose scales are large enough to record all these quantities are usually so sluggish in regard to time that on the comparison of the records is very unsatisfactory. In order to study the relationships between temporary and fleeting phenomena, it is necessary that all instruments should record upon the same sheet of paper, so that the same time-scale will answer for all.

The instruments that respond most nearly to the general needs of meteorology are the various forms of meteorographs devised by W. Babcock for use at St. Petersburg, by Sprung and Fuss for use at Hamburg and Berlin, and by Marvin for Washington. The photographic systems for pressure and temperature introduced many years ago at stations in Great Britain and the British colonies are not quite adequate to present needs. The portable apparatus manufactured by Richard Frères at Paris is in use at a very large number of land stations and on the ocean, and by giving special care to regular control-observations of time, pressure and temperature, important results may be obtained; but in general the time-scales are too small, and the unknown sources of error too uncertain, to warrant implicit reliance upon the records.

Polarimeter.—The brightness and blueness of the sky light, and especially its polarization, have been observed with increasing interest, as it seems possible from these elements to ascertain something with regard to the condition and amount of the moisture in the air. With the aid of this new, and turned slowly about the axis of vision one can quickly recognize the fact that the sky light is polarized, and that the polarization is largely due to the air or dust lying between us and the clouds in the distant horizon. Arago, with a more delicate form of polariscope, determined the existence of a so-called neutral region near the sun. Babinet located a neutral point or zone about as far from the anti-sun as was Arago's from the sun itself. Brewster discovered a neutral point near the sun and horizon, disappearing when the sun is more than 12° above the horizon. Finally, Brewster established the fact sufficiently to draw lines of equal polarization, which he published in Johnston's Physical Atlas, and which were confirmed by Zantedeschi in 1849. Since those days far more delicate work has been done—first by Bosanquet of Oxford, afterwards by Prof. E. C. Pickering of Harvard University and Prof. A. W. Wright of Yale University. A later contribution to the subject is by Jensen (see Met. Zeiti. for Oct.-Dec. 1899), who has observed the brightness as well as the polarization, and thus completed the data necessary for testing the various physical theories that have been proposed for the explanation of this phenomenon. We owe to Tyndall the discovery that when a beam of white light penetrates a mass of fine aqueous mist the latter sends off at right angles a delicate blue light, which is almost wholly polarized in a plane at right angles to the plane...
of reflection. As the particles of mist grow larger, the blue light becomes whiter and the polarization disappears. The original vapour particles are undoubtedly so small as to be comparable in size with a fraction of the wave-length of ordinary light, and Rayleigh was able to show that molecular as well as minute particles must have a power of selection, and that the diffused sky light comes to us by selective reflection. On this basis we should expect that in the driest air at great heights, where the temperature is low and condensation has but just begun, and the dust particles are rare, there would occur the smallest aqueous particles reflecting light of the intensity but the largest percentage of polarization. Rayleigh has shown that it is quite possible that the molecules of oxygen and nitrogen constituting the atmosphere may also exercise a diffuse selective reflection, and contribute to the brightness and polarization that are mainly due to aqueous vapours.

(See Sky.)

We thus see the theoretical importance of adding photometry and polarimetry to the work of a meteorological observatory. The apparatus to be used in this connexion will vary somewhat with the exact character of the observations to be made. The most extensive researches that have yet been carried out in this line with an apparatus devised by the late Mr. J. C. Maxwell, Cornu, Pickering, Kimball, Nichols, and especially Rubenson, who in fact recommended that polarimetry and photometry should go hand in hand. In order to measure the position of the plane of polarization of the sunlight, and thus the direction of the lines of force, measure the percentage of polarized light, Mascart’s modification of the Savart is better. In order to measure the general brightness of a spot in the sky, Jensen has used a slight modification of the Weber photometer, and in fact Weber himself has applied the same method to the measurement of the daylight. The complete work of Jensen was published in the Schriften of the Scientific Association of Schleswig-Holstein in 1886, and, like the memoir published by Rubenson in 1863, it gives the meteorological conditions in full as a basis for the investigation of the connexion between sky light and the moisture in the atmosphere. In his work 1900–1905 with Angstrom’s photometer, Mr. A. H. Kimball of Washington has advantageously used the Pickering photometer, and has shown that the transparency of the air and the polarization of light go hand in hand.

Cyanometer.—The cyanometer devised by Arago to measure the blueness of the sky consisted of an arbitrary scale of blues on a strip of porcelain, with which one could compare the blue of the sky. This comparison, however, is open to many subjective errors. A more satisfactory apparatus is Zollner’s photometer, or some equivalent, in which a patch of white surface is illuminated by any particular tint or combination that may be desired. In fact, Maxwell’s colour-box admits of ready application to the analysis of sky light, and reveals at once the proportions of red, yellow, and blue that may be contained therein.

Dust-counter.—The importance of observing the dustiness of the atmosphere has been especially realized since the invention and use of various forms of apparatus for counting the number of particles of dust in a small volume of air. These inventions are due to Mr. John Aitken, of Edinburgh.

The latest form of his apparatus is the very convenient “pocket dust-counter.” In this the air contained in a small receiver is rendered dust-free by centrifugal forces; the dust thus falling out into the vapour to condense upon the dust, which, becoming heavy, falls to the bottom, so that in a short time all is removed. A small stop-cock is now turned, so as to allow a definite small quantity of air to enter and mix with the dustless air in the receiver. The dusty and the dustless airs are now thoroughly mixed, and again the whole quantity within the receiver is expanded, and the dust nuclei fall down by the condensation of vapour upon them. Assuming that the mixture is represented by a minute droplet of water, we have but to count the latter; this is easily done by causing all the drops to fall upon a polished plate of black glass, which is divided into small squares, each of which is rendered with a positive point; only each of these squares represents a small fraction of a cubic centimetre of air; thus in one case the number of fog particles averaged 2-6 per square millimetre of the glass plate, and, as the multiplying factor was 100, this corresponded to 200 cubic centimetres of dust in a cubic centimetre of air. The cleanest air has been found in the West Highlands of Scotland, where 16 particles per cubic centimetre was once recorded as the minimum; while 76,000 was the maximum. On the Rigil Kulin, in Switzerland, the cleanest air gave 210, and the dustiest 16,500. On comparing the records of the dust-counter with the record of the apparent state of the air, Mr. Aitken found that 500 particles per cubic centimetre corresponded to clear air, and 1900 to a thick haze in which distant mountain tops were hidden. In the cities the particles of soot and effluvia of all kinds act as dust, and both in London and Paris the numbers range as high as 80, 110, 150 and 210 per thousand cubic centimetres.

Electrical Apparatus.—The electrical phenomena of the atmosphere undoubtedly belong to meteorology, and yet the methods of observation have been so unsatisfactory and the difficulty of interpreting the results has been so baffling that regular observations in electricity are only carried out at a very few meteorological institutions. A general summary of our knowledge of the subject was prepared by J. Elster and H. Geitel for the International Congress held at Chicago in 1893, but since that date the methods and apparatus of observation have received important modifications.

In general the water-dropping collector of Lord Kelvin, arranged for continuous record by Mascart, continues to be the best apparatus for continuous observation at any locality, and a portable form of this same apparatus is used by explorers and in special series of local observations. In order to explore the upper air the kite continues to be used, as was done by A. J. McAdie for the Weather Bureau in 1885 and by Weber at Kiel in 1889. The difference of potential between the upper and lower part of a kite-shaped light balloon has been measured up to considerable altitudes by Elster and Tuma. In general it is known that negative electricity must be present in the upper strata just as it is in the earth, while the surrounding layer of air is positively electrified. The explanation of the origin of this condition of affairs is given in the recent researches of Sir J. J. Thomson (Phil. Mag., Dec. 1899), and his interpretation

![Fig. 6.—Marvin-Hargrave Kite, with Meteorograph in position.](image)

is almost identical with that now recognized by Elster (see Terrestrial Electricity, Jan. 1900, p. 213). According to these results, positive and negative ions exist in the upper strata and are carried up with the ascending masses of moist air, then the condensation of the moisture must begin first on the negative ions, which are brought down eventually to the earth’s surface. The earth receives its negative charge from the atmosphere, leaving a positive charge or an excess of positive ions in the middle air. (See G. C. Simpson, "Atmospheric Electricity," Monthly Weather Review, Jan. 1906, p. 16.)

The observations of atmospheric electricity consist essentially in determining the amount and character of the difference of potential between two points not very far distant from each other, as, for instance, the end of the pipe from which the water-drops are discharged, and the nearest point of the earth or buildings resting on the earth. The record may have only an extremely local value, thus the investigations of Professor John Trowbridge of Harvard University, made in conjunction with the U.S. Weather Bureau in 1882–1885, show that the differences vary so much with the winds, the time of day, and the situation of the water-dropper that the mere comparison of records gives no correct idea of the general electrical relationships. It has been suggested that possibly daily telegrams of electric conditions and daily maps of equipotential curves over the North American continent could be prepared. But it is undeniable that much work is still to be done before the results of these measurements can be satisfactorily interpreted. It is not yet known how atmospheric electricity (in connection with atmospheric electricity.)

Aerial Research.—The exploration of the upper atmosphere is to be regarded as the most important field of research at the present time; the kite and the balloon enable observers and apparatus to be carried to considerable heights, though by no means so far as is desirable. The kite was first used in meteorological work by Alexander Wilson at or near Glasgow in 1749, and has since then been frequently used by English observers. It was used in 1867 by Albe in studying the winds under a thundercloud, and in 1877 in
studying the depth of the ocean breeze on the coast of New Jersey, but the later revival of interest in the subject dates from the work done in England in 1882 by E. D. Archibald, who used the kite to carry up anemometers to very considerable heights, and thereby determined the relative movement of the air in the free atmosphere. In 1889, Marvin McAdie used the kite in his studies of atmospheric electricity, Professor Cleveland Abbe proposed to use it for a complete exploration as to temperature, moisture and wind, but W. A. Eddy of New York first forced its varied capabilities upon public attention, and accepted the suggestion of Professor Cleveland Abbe to employ it for meteorological work. Having shown his kite at the Blue Hill Observatory, and having carried up with them the self-registering apparatus devised by Mr. Ferguson, Eddy left the further prosecution of this work to Mr. Rotch, who has made this a prominent feature of the work at his observatory, having carried up meteorographs to the height of 15,000 feet by means of a series of kites flying in tandem. The officials of the U.S. Weather Bureau have developed the admirable cellular kite, invented by Hargrave of Australia, and Professor Marvin's works on the theory and construction of this form are well known.

The general appearance of the Marvin or Weather Bureau kite, his reel and other apparatus that go with it, and his meteorograph, are shown in Figs. 6, 7, 8. The size ordinarily used carries about 68 sq. ft. of supporting surface of muslin tightly stretched on a light wooden frame. The line, made of the finest steel piano-wire, is wound and unwound from a reel which keeps an automatic record of the intensity and direction of the pull. The reel is in and out may be done by hand, but ordinarily demands a small gas-engine. The observer at the reel makes frequent records of the temperature, pressure and wind, the apparent angular elevation of the kite, and the length of wire that is played out. At the kite itself the Marvin meteorograph keeps a continuous record of the pressure, temperature, humidity and velocity of the wind. The meteorograph, with its aluminum case, weighs about two pounds, and is so securely lashed behind the front cell of the kite that no accident has ever happened to one, although the kites sometimes break loose and settle to the ground in a broken country many miles away from the reel.

On four occasions the line has been completely destroyed by slight discharges of lightning; but in no case has the kite, the observer, or the reel been injured thereby. Of course, such lightning is preceded by numerous rapidly increasing sparks of electricity from the lower end of the wire, which warn the observer of danger. During the six months from May to October 1898, seventeen kite stations were maintained by the U.S. Weather Bureau in the region of the lakes, the Upper Mississippi and the Lower Missouri valleys, in order to obtain data for the more thorough study of atmospheric conditions over this particular part of the country. During these months 1217 ascents were made, and as no great height was attempted, mostly under 7000 or 8000 feet. There was thus obtained a large amount of information relating to the air within a mile of the earth's surface. The general gradients of temperature, which were promptly deduced and published, H. C. McAdie, in a bulletin of the Weather Bureau, gave for the first time in the history of meteorology trustworthy observations of air temperatures in the free atmosphere in numbers sufficient to indicate the normal condition of the air.

The kite and meteorograph have now been adopted for use by all meteorologists. The highest flight seems to be that of the 3rd of October 1907, at Mt. Weather in Virginia, when 23,140 ft. above sea-level or 21,385 ft. above the reel was attained by the use of 37,300 ft. of wire and 8 kits tandem.

The balloon was used for the scientific exploration of the atmosphere quite freely during the 19th century. The first important voyages were those of Gay-Lussac and Biot at Paris in August and September of 1804.

The next important ascent was that of Bixio and Barral in 1850 at Paris. The most remarkable ascent that has been made has been that of James Glashier, and of September 1862, and Benson at Berlin in 1859; on both of these occasions the aeronauts attained altitudes of from 30,000 to 35,000 feet. Systematic ascents at many points in Europe simultaneously on pre-arranged days were made during the years 1870-1879, and led to the development of a general international system of ascension on pre-arranged days of the year that is now a very important feature in the study of the atmosphere.

![Fig. 7. Marvin Kite Reel for hand power.](image)
![Fig. 8. Marvin Kite Meteorograph.](image)
Sag balloon soundings have been made not individually, but by a pre-arranged system, simultaneously in combination with the ascension of apparatus above mentioned. The balloons made their way to the South Pole with the assistance of the N. and S. In these cases, the balloon is guided to the desired point by radio signals from the ground. They gave rise to the great results which the discussions to which they gave rise have emphasized the importance of increasing the sensitiveness of the self-recording apparatus. The mechanical, hydrostatic, and the thermometric, and of providing more perfect protection against radiation from the sun or to the sky. It is believed that accurate records may be attained up to at least 30,000 metres, but as the mechanical apparatus is now not attainable and the records obtained are still under considerable criticism on account of instrumental defects. In general the wind that supports a kite also furnishes sufficient ventilation for the thermometer; but in the case of the sounding balloons as used in the future, the balloons float along horizontally in the full sunshine, a strong artificial ventilation must be provided. Moreover, the sluggishness of the best thermometers is such that during the rapid rise the records of temperature that are being made at any moment really belong to some altitude considerably below the balloon, and a most critical interpretation of the records is required. Notwithstanding all criticisms, however, the balloon work in all localities agrees in showing the existence of a region above the 10,000-metre level, where temperatures cease to diminish rapidly, and may even become stationary.

III. PHYSICAL AND THEORETICAL METEOROLOGY

The ultimate aim of those who are devoted to any branch of science is to penetrate beyond the phenomena observed on the surface to their ultimate causes, and to reduce the whole complex of observations and empirical rules based upon limited experiences to a simple deductive system of mechanics in which the conclusions are to have the same quality, or shall be deduced from the few simple laws that underlie the structure of the universe. A correct "theoria" or physical and logical argumentation, deducing from primary laws all the phenomena constitutes the noblest achievement of man in science. It is by such works that Newton and Laplace distinguished themselves in astronomy. The development of the true physical and mechanical theories of atmospheric phenomena has made great progress, but is still inferior in completeness to astronomical work, owing to the great complexity of the meteorological problems. The optical and the thermal phenomena have been very satisfactorily elucidated, the electrical phenomena promise to become clear, but the phenomena of motion or aerodynamics have only been elucidated to a limited extent. We must, however, introduce the reader to some of the works that have been published on the subject, in the hope that thereby he will himself be persuaded to further study and stimulated to contribute to our knowledge.

Between the years 1853 and 1861 Professor William Ferrel published in Gould's Astronomical Journal, Runkle's Mathematical Journal, and several other reviews, several papers on the motions of solids and fluids relative to the earth's surface. His work resulted in the elucidation of the problems of the atmosphere, and in engineering as applied to the entire universe, and analytically relevant to the archimedian method of quadratures or graphs of geometry, he deduced important relations between the density of the air, the barometric pressure, and the ascending winds. His essays seemed to show that it might be possible to treat the complex problems of meteorology logically and deductively, and he attempted to do so. The fundamental formulae of mechanics. A beautiful memoir on the steady motions of the atmosphere was published in 1868 in the Annales des sciences physiques and mathematics by Professor Adolph Barus, and is now reprinted in vol. ii. of Abbe's Mechanics of the Earth's Atmosphere. Esdy's, Coffin's, Henry's and Ferrel's ideas were the basis of the system of daily weather predictions published by the present writer and brought to perfection by Weather Bureau Survey. Subsequently this work was taken up by the government, and greatly enlarged during 1871-1891 by the chief signal officers of the army, and after 1891 by the chiefs of the U.S. Weather Bureau. It was the ability of the above authors to get meteorologists in consequence of reviews published by Hann in the Zeitschrift of the Austrian Meteorological Society in January 1875, but especially after they had been reprinted for the first time by the U.S. Signal Corps in 1885. In 1881 Ferrel, after finishing his work on the tides for the U.S. Coast and Geodetic Survey, began a new and extensive series of meteorological contributions, three of which were published by the U.S. Coast Survey and the rest by the Signal Office. Stimulated by the urgent needs of the modern weather bureaus throughout the world, and by the beauty of the mathematical problems presented, numerous mathematicians have taken up the study of the earth's atmosphere, so that the literature of the subject is now far more extensive than is generally supposed, including memoirs by Helmholtz, Kelvin, Bjerkes and other famous men.

Based on the theoretical and mechanical problems, the numerous physical problems have also been carefully treated, both experimentally and mathematically. The problems of radiation have been studied by Langley, Hutchins, Angström, Paschen, Voigt, Maurer, Croys, Humboldt, Nobles, Traub, Tracy, and Coblenz. The thermodynamic problems have been especially developed by Kelvin, Hertz, von Bezoeld, Ferrel, Brillouin, Neuhoff, Bigelow and Margules. Very extensive and successful investigations in the formation of rain-drops have been studied by an optical method by Carl Barus, and with brilliant success, from an electrical point of view, by C. T. Wilson and Sir J. J. Thomson at the Cavendish Laboratory, Cambridge, England.

In a complete study of the mechanics of the earth's atmosphere we naturally begin by expressing in simple analytic formulae all the various conditions and laws according to which every particle of the air must move. Some of these conditions are local, depending upon the resistances at various points of the earth's surface; others are of the nature of discontinuous functions, as, for instance, when the ascent of moist air above a certain level suddenly gives rise to condensation and clouds, to the evolution of latent heat, to the precipitation of rain, to the shading of the air and the ground below the cloud, and to the absorption of heat by the upper surface of the earth. Hence it seems a hopeless task to solve all the problems of the atmosphere can ever be resolved by purely analytical methods; there must be devised combinations of numerical value, and physical, and physical problems involved in the condition of the atmosphere and give us special solutions adapted to particular cases. But even these special methods can only be perfected in proportion as we attain approximate solutions of the simpler problems. And it is in this preliminary work that a good beginning has already been made.

The present state of theoretical physical and mechanical meteorology cannot be fully presented in non-technical English text. It is necessary to employ algebraic formule, or numerical tables, or graphic diagrams, the former being certainly the least cumbersome and the most generally available. The uniform system of notation devised by Professor F. H. Bigelow, and a very complete summary of the formulae of physical meteorology expressing the results of many recent students will be found in chapters x. and xi. of his Report on the International Cloud Observations, published as vol. ii. of the annual report of the chief of the U.S. Weather Bureau for 1898-1899.

The fundamental laws to which the atmosphere is subject are as follows:

A. The Equation of Elastic Pressure. The pressure shown and measured by the barometer is an elastic pressure acting in all directions equally at the point where it is measured, and which would exist if there were a uniform distribution of a substance throughout the earth. It is a uniform distribution of a substance through the earth's atmosphere, expressed for any given pressure. This pressure is the pressure of the air of a prescribed chemical constitution would have a prescribed definite weight. The general relations between absolute temperature, pressure and volume are expressed by the formula

\[ p = RT \]

where \( T \) expresses the absolute temperature, \( p \) the elastic pressure, \( v \) the volume, and \( R \) is a constant which differs for each gas, being 29-2713 for ordinary dry air and 47-060 for pure aqueous vapour, if we use as fundamental units the kilogram, metre and second.

B. Huyghens' Law. The pressure of the atmosphere at any place depends primarily on the weight of the superincumbent mass of air, and therefore diminishes as we ascend to greater heights. If the air is in motion, that and other considerations come into affect the pressure; but if the air is quiet relative to the earth's
surface, then the pressure at any altitude is expressed by the so-called barometric or hygrometric formula

\[ p = p_0 - \rho gh \]

(2)

where \( \rho \) is the density and \( g \) the apparent gravity for each layer of air whose vertical thickness is \( dh \). The integral of this formula depends upon the layer, \( h \), the pressure at the bottom, \( p \), the latitude of the station, \( h \), the elevation above sea-level of the lower limit of the stratum, and \( h, k \) that of the upper limit. The modifications which this formula needs in order to adapt it to other hypotheses representing more nearly the actual distribution of temperature, moisture and gravity, have been elaborately investigated by Angot in a memoir published in 1899 in the Memoirs of the Meteorological Bureau of France for the year 1896. Angot, Hergesell and Ryatcheff have also shown that for hygrometric work of any pretensions to accuracy it is simplest and best to use Laplace’s formula for surface conditions as a basis and to adjust the individual results rather than attempt a more complex single formula for the whole stratum; yet the latter seems to be essential for work in aerodynamics.

C. Thermodynamic Relations.—The temperature of the air is due to the quantity of molecular energy that is present in the form of heat, but usually there is also a quantity of molecular energy that is spoken of as potential heat. This latent heat is said to be internal work, such as melting ice or boiling water, while the sensible heat does external work, such as expanding and pushing in all directions. These molecular energies can also be transformed into one another without appreciable loss, and this power of transformation is expressed by the various equations of thermodynamics, of which the fundamental one for our purpose is

\[ \frac{dQ}{dV} = C + \frac{m}{V} \frac{dP}{dV} \]

(3)

This equation expresses the fact that, in a quantity of heat measured in calories, \( dQ \), is added to or taken from a mass of dry air, there may result both a change of temperature, \( dt \), corresponding to one portion of the heat, \( Cdt \), and a quantity of external work corresponding to the remaining portion of the heat. The latent heat is the excess that usually happens that the quantity of heat in a given mass of air does not remain the same for any length of time; it is diminished by radiation or is increased by reflection; and a temperature quantity is lost when rain, snow or hail drops down from the air, while a quantity is added to the atmosphere when moisture evaporates and mixes with the dry air as invisible vapour, even the passage of water, the condensation of the former into water. The most important and the first change that the meteorologist has to contemplate when he undertakes the study of a change is that the change in the quantity of heat may be considered as temporarily negligible. In these cases \( dQ \) is zero; the changes in temperature balance the changes in external work, and the thermal process is said to be adiabatic.

D. The Condition of Continuity.—When a mass of liquid or gas grows through several motions and changes without being disturbed or otherwise broken into smaller portions, and without the formation of either local condensations into solid or liquid masses or of bubbles and vacuous spaces in its interior, and when all the changes that go on proceed by gradual and continuous processes as to time, then the mass of the fluid is subject to the law of continuity as to mass, and the motion of the fluid is continuous as to velocity. These conditions are assumed in elementary hydrodynamics, and are implied in the process of integration, and in the equation of continuity

\[ \frac{\partial p}{\partial t} + \frac{\partial (ptu)}{\partial x} + \frac{\partial (ptv)}{\partial y} + \frac{\partial (ptw)}{\partial z} = 0 \]

(4)

where \( \rho \) is the density, \( t \) is the time and \( \xi \) the ordinary symbol for partial differentiation. But the fact is that meteorologists have to deal with air masses which in some states of the atmosphere are subject to discontinuous changes of conditions. This is the result of condensations such as insolating at sunset and renewed daily; radiations of heat changing abruptly with land and ocean and cloudiness and snow covering; discontinuous changes in conditions and processes at the earth’s surface altering at every change from mountains to plains; discontinuous masses changing with additions and abstractions of moisture, rain and snow—all which lead to discontinuous vortex motions and overturnings and rearrangements of the atmospheric strata. The only factors that are continuous for any length of time or extent of area are the rotation of the earth and the attraction of gravitation. In the presence of such changes which include the solution of very special local definite problems or to the general statistical problems of our atmosphere.

E. Conditions as to Energy and Motion.—When the total quantity of heat is both latent and sensible, remains constant or changes in a continuous manner, and when the motions are continuous, the mechanical and thermal processes are expressible by ordinary differential equations that involve both energy and inertia, and are subject to conditions expressed by the following equations of hydrodynamics:

\[ a. \text{ Equations of energy.} \quad \text{In the kinetic energy T, the potential energy V, the total energy W: } W = m + n \text{ be cosines of the angle between the pressure } p, \text{ and the inwardly directed normal to the boundary. Then will } \]

\[ \frac{dW}{dV} + W = f \]

(5)

\[ b. \text{ Equations of acceleration and inertia.} \quad \text{Let } P \text{ be the potential of the external forces acting on a unit mass of the atmosphere; } \mu \text{ be the coefficient of viscosity or internal friction. Then will } \]

\[ \frac{dP}{dv} - \frac{dP}{dv} = g \frac{dV}{dv} + \frac{dV}{dv} \]

(6)

Approximate Assumptions and Solutions.—After introducing into the preceding system of fundamental equations (1–6) the actual conditions as accurately as they are known relative to gravity, solar radiation, the rotation of the earth, the variable mass of moisture, the precipitation of rain and cloud, the mutual interconversions of latent and sensible heat, a special difficulty occurs when we attempt to express analytically the initial conditions of the atmosphere as to temperature and pressure, and many boundary conditions as between the rough earth’s surface on its lower side and the unknown outward surface on its upper side. As the true earth’s surface cannot be represented by any simple algebraic formula, it is customary to assume that it is a uniform sphere, neglecting at least partially, if not wholly, the spherical shape. We may first assume that there is no interaction between the earth and the air, but must afterwards make allowance for its influence. Thirdly, we assume that the action of the earth’s surface to heat the air and to throw moisture into evaporation into the atmosphere is negligible. Finally, in many cases we go so far as to assume that the atmosphere is an incorporeal rare liquid having a uniform density and a uniform depth of about 8000 metres, corresponding to the average standard density of dry air under a pressure 760 mm; the temperature is maintained at 0°C. Even under these simplifications the analytic difficulties have been too great to admit of rigorous solutions, except in the case of the simple gradient.

The treatment of atmospheric problems by Ferrel was followed by an equally ingenious mathematical treatment by Professors Guildberg and Mohring of Christiana, in two papers published by them in 1876 and 1880 respectively. These authors, like Ferrel, treated isolated portions of the atmosphere and obtain special solutions, which, however, have not the generality that must eventually be demanded in a rigorous and general discussion of the atmosphere movements. This subject was again treated out of the main work in 1882 by Quebeck, of the university of Hanover, in the Ann. Phys. xvii. 128. But even Oberbeck’s solutions are obtained under various simplifying assumptions that restrict their satisfactory application to the daily weather conditions. Oberbeck’s first memoir treats of the mechanics of stationary cyclic movements. Assuming that the isobars are concentric circles, and that in the outer portion of a cyclone the air has only horizontal motions, he evolves his system of equations for the inner and outer regions of the cyclone separately. He shows that in general the pressure increases on all sides of a cyclone; in the inner portion it has only vertical motions, he solves his system of equations for the inner and outer regions of the cyclone separately. He shows that in general the pressure increases on all sides of a cyclone; in the inner portion it has only vertical motions, he solves his system of equations for the outer region, and as a result of these two equations concludes that in the inner portion at its outer edge there must be an increase of pressure; he concludes that in the outer region there must be a decrease of pressure; he concludes that in the inner region of the air must be considered as a spiral inflow from all sides towards the centre. But the angle between the wind and the gradient differs in different laws in the outer and inner regions, depending on the position of the
earth and the friction, but in the latter also on the intensity of the ascending current of air. In passing from the outer to the inner surface of the atmosphere we find that the directions of the winds are not continuous, although the movement and the barometric pressures are assumed to be continuous. This latter peculiarity does not occur in nature, and is undoubtedly an analogy, similar to Oberbeck's method of treating the fundamental equations.

An improvement in the mathematical analysis was introduced by Dr F. Pockels of Göttingen in a memoir published in the Met. Zeit. in 1889. Pockels reduces every change in the equations of the wind to changes of the temperature, pressure, wind, and barometric pressure. By eliminating the equations of state the relations between the velocity, temperature and pressure, can be obtained. Notwithstanding the fact that many of these changes are not precisely measurable, the results are highly interesting. The results of the investigation by Pockels and the equations of the wind, and barometric pressure, give the opportunity of a better understanding of the atmospheric conditions.

The atmospheric movements are most important in the upper strata, where the temperature is lower and the pressure higher. The upper strata are more subject to the influence of the earth's rotation and the earth's curvature. The results of the investigation of the upper strata show that the movement is more rapid and the influence of the earth's curvature is more pronounced in the upper strata than in the lower strata. The investigations of the upper strata show that the movement is more rapid and the influence of the earth's curvature is more pronounced in the upper strata than in the lower strata.

The atmospheric movement in the upper strata also shows a different character from that in the lower strata. The movement in the upper strata is more rapid and the influence of the earth's curvature is more pronounced in the upper strata than in the lower strata. The investigations of the upper strata show that the movement is more rapid and the influence of the earth's curvature is more pronounced in the upper strata than in the lower strata. The investigations of the upper strata show that the movement is more rapid and the influence of the earth's curvature is more pronounced in the upper strata than in the lower strata.

The atmospheric movement in the upper strata also shows a different character from that in the lower strata. The movement in the upper strata is more rapid and the influence of the earth's curvature is more pronounced in the upper strata than in the lower strata. The investigations of the upper strata show that the movement is more rapid and the influence of the earth's curvature is more pronounced in the upper strata than in the lower strata. The investigations of the upper strata show that the movement is more rapid and the influence of the earth's curvature is more pronounced in the upper strata than in the lower strata.
of upper winds shown by the higher clouds, namely, south-westernly in the northern hemisphere and north-westerly in the southern.

Halley in 1680, and Hadley in 1735, recognized this erroneous or imperfect explanation of the phenomena that bring about these winds. As some errors in regard to this subject are still current, it is necessary to say that it is erroneous to teach that atmospheric air weighs less than the earth, in consequence of the motion of the atmosphere, and that therefore the barometer fails. The addition of more moisture must increase its weight as a whole; heat, being imponderable, cannot directly affect its weight; and whatever other influence the world "lighter," since it means both a diminution in absolute weight and a diminution in relative weight or specific gravity. Heat and moisture may diminish the specific gravity by evaporation of air in the earth's atmosphere, as in any given volume by diminishing its mass, but neither of them can of themselves affect the pressure shown by the barometer unless so far as that is due to the weight of the atmosphere. The pressure, and therefore the density, diminishes rapidly with diminishing its specific gravity and causing it to rise, so that colder air flows in to take its place, we thereby diminish the barometric pressure. It is easily seen that if the expression \( p = \rho g / h \), which, as we have before said, is the law of elasticity, \( T \) and \( s \) may very as to counterbalance each other, and allow the pressure \( p \) to remain the same. Within any given room or other enclosure hot air may rise on one side, flow over to the opposite, cool and return, and the circulation be kept up indefinitely without any necessary change in pressure. The problem of the relation between wind and pressure in the free atmosphere is more difficult and involves the whole process of the thermal laws of the masses of air that are in motion with the earth around its axis. The air is so extremely mobile that it moves nearly in response to slight differences in pressure, but not the least to the forces that at any time change the wind; it is, so to speak, the heart of the atmosphere. The barometric pressures of the winds, but are equally and essentially the results of the winds. They are primarily due to the fact that the atmosphere is rapidly revolving with the surface of the earth around its axis, while at the same time it may be circulating about a storm centre. Inappreciable differences of pressure start the winds in motion, and the air moves towards the region of low pressure, just as in the pneumatic despatch tubes the flow of air towards the point the air is carried along. But in the free air, where there are less important resistances to be overcome, the freedom of motion is greater than in these pneumatic tubes. No wind is ever seen to blow from the south towards the north, all sides towards the central low pressure than it rapidly acquires a spiral circulation, and thereby there is superimposed on the earth's atmosphere a decided diminution of pressure on the left hand side of the wind, and the pressures of the wind overcomes resistances, but the gradient of pressure, perpendicular to the wind, is diminished, is the same that exists from the top of the wind, and that which produces the areas of decided low pressures that appear as storm centres on the daily weather map. Therefore, in general, the wind cuts across the charted isobars in oblique angles, and in the westerlies and north-westerlies the winds far removed from the centres, but which are almost zero for the most violent winds near the low centre. The winds acquire the velocity of the air thus set in motion, and they may be so rapid that they seem to be driven by a local pressure of the earth, and the resistances of the earth's surface, as first explained by Ferrel, seems to have been neglected by meteorologists until brought to their attention by auditorly have been explained by Ferrel's work (see Met. Zeit. 1874). The independent investigations of Sprung, Koeppen, Finger, and especially Guldborg and Mohn, confirm the observations of Ferrel.

It is quite erroneous to imagine that the low pressures in storm areas and in the polar regions, and especially the belt of low pressure at the equator are due simply to the diminution of the density and weight of the air by the rotation of the earth, and the abundant rainfall as relieving the atmosphere of the weight of water. It has been clearly shown that none of these operations can directly affect the barometric pressure; the only accessible effect, which has opened the way for modern progress in theoretical meteorology.

Both Esph and Han have abundantly shown that the formation and downfall of rain do not produce any low barometric pressure, and that the opposite results are due to a more rapid rotation of the earth at the poles than at the equator, and that the latent heat evolved by the condensation of vapour into rain may so warm up the cloud as to produce a temporary rise in pressure. Even at the surface of the earth, an isolated storm may be produced by the sudden expansion of the cloud. [The details of the thermodynamics of this operation have been elucidated by Wm. von Bezo.] The force with which the wind presses to the right or left to be deflected in that direction is 2\( r \sin \phi \), while the curvature of the path of the wind is measured by its radius of curvature, which is \( \pi / 2 \sin \phi \), where \( r \) is the velocity of the wind, \( \phi \) is the equatorial velocity of the earth's rotation, and \( \phi \) is the latitude. It will be seen from this that there is no deflection at all at the equator; therefore, as Ferrel stated, there is no tendency to the formation of great whirlwinds at the equator, hence hurricanes and typhoons are not found there.

Ferrel frequently speaks of an anti-cyclone, whereby he means the area of high pressure just outside of a strong cyclonic whirl; the expression peri-cyclone would have been more appropriate and is sometimes substituted. The term cyclone among meteorologists and the term whirlwind in the United States, is equivalent to the older usage of whirlwind, and it is unfortunate that misunderstandings often arise because the term is used by meteorologists when the air moves in whirling winds that in centuries been called a tornado. The mechanical principles discussed by Ferrel led him to an algebraic relation between the barometric gradient \( G \), the wind velocity \( v \), the radius of curvature of the isobar \( r \), and the inclination \( v \) between the wind and the isobar, which is

\[ \frac{G}{v^2} = \frac{1}{r} \sin \phi \]
expressed by the following formula for the pressures that prevail at sea-level:

\[ G = (2\sin \phi + \cos \phi) \rho \sec 1 \] [8\,000,000,000].

A popular exposition of this and other results of Ferrel's work is given by Archibald in "Weather, Climate, and Weather Prediction," revised and still devoted to "Our Trains on the Winds" (New York, 1889, and later editions).

The charts of mean annual pressure, temperature and wind above referred to show certain broad features that embrace the whole system. The low pressures and highest temperatures are in the equatorial and polar regions, the high pressures under the tropics, the trade winds below and the anti-trades above, with comparative calms under the belts of equatorial low pressure and tropical high pressure. In such a world as we have described, it was to explain how these mean average conditions depend upon each other, and to devise a system of general circulation of the wind consistent with the mean average conditions. As we have already said, such a system may be very far from that presented by the real atmosphere, and little by little we are being led to a different view of the question of the general circulation. The earlier students of storms generally accepted one of two views as to the cause of whirlwinds. They were either (1) formed mechanically between two principal currents of air flowing past each other, the so-called polar and equatorial currents; or (2) they were due to the change of buoyancy of air while the heavier air flowed in beneath, the whirling motion being communicated by the influence of the earth, or by the greater resistances on one side than on the other. In order to get rid of the first theory, Dr. E. Her mann in a memoir of which a translation is published in the bulletin of the American Society of Civil Engineers, June 1896, of course Hermann's own investigation is also based upon certain simplifying hypotheses, such as the absence of outside forces and the assumption that the fluid is an absolutely incompressible, or an absolutely dry, ascendant from high altitudes above Canada on the eastern slope of the Rocky Mountains, but driven southward by an excess of centrifugal energy added to a moderate barometric gradient. It is evident that such grand over-turnings of the descent of masses implies energy communicated by the action of gravity, but the whole mechanism of this process was not clear until the publication by Margules of his memoir "Ueber die Energie der Stürme" (Vienna, 1903), which will be referred to hereafter.

Mathematics have, almost without exception, assumed a so-called steady condition in the motion of the atmosphere in order to achieve a successful integration of the general equations of motion. The restrictions within which Helmholtz and others have worked, and the limits within which their results are to be accepted, have been summarized by Professor E. F. Appleton in his memoir "The Energy of Fluid Motions in the Atmosphere" (London, 1907). In general, the movements in the atmosphere must consist not only of an interchange between the poles and the equator, but also of east and west motions, and there is no possibility of a steady state. The second step in this inquiry is, Can these movements become perfectly steady with this unvarying or steady distribution of temperature? In other words, Can the temperature and the winds be so adjusted that the atmospheric circulation be invariable within any given set of conditions? That is exactly the question that Hermann's researches aim at answering.

In other words, Can the temperature and the winds be so adjusted that the atmospheric circulation be invariable within any given set of conditions? That is exactly the question that Hermann's researches aim at answering.
in the heat received from the sun; for instance, what variation in the earth's atmosphere corresponds to the periodic variations of the solar spots. The general current of Helmholtz's investigations shows that a periodic change in the earth's atmosphere may be maintained for any length of time by a given periodic influence outside of the atmosphere. On the other hand, it is barely possible that wave and vortex phenomena in the sun's surface may have the same physical reality as regular phenomena in the earth's atmosphere, so that there may be a parallelism without any direct connection between the two.

An important paper on the application of hydrodynamics to meteorology is that by Professor V. Bjerknes, of Stockholm, Sweden, which was read in September 1899 at Munich, and is now published in an English translation in U.S. Geol. Survey Circ. 123. "On the Application of Hydrodynamics to Meteorology." (1906). In this memoir Bjerknes applies certain fundamental theorems in fluid motion by Helmholtz, Kelvin, and others, to the problems of atmospheric circulation. He simplifies the hydrodynamic conceptions by dealing with density directly instead of tension and pressure, and uses charts of "isodensities" or lines of equal density, very much as was proposed by Abbe in 1889 in his Preparatory Studies, where he utilized lines of equal buoyancy or, "isotherms," and such as Elkholm published in 1891 as "isothermal" and which were called "Luycks" by Müller-Haefele. Bjerknes has thus made it practicable to apply hydrodynamic principles in a simple manner without the necessity of analytically integrating the equations, at least for many ordinary cases. He also gives an important criterion for predicting the existence of an isodensity between the physical theory, according to which cyclones are perpetually renewed, and the mechanical theory, according to which they are simply carried along in the general atmosphere. In this memoir, Bjerknes' paper is illustrated by an average one due to Mr Sandström, of Stockholm, who has applied these methods to a storm of September 1898 in the United States. The further development of Bjerknes' methods promises to lead to a considerable advance in theoretical and practical meteorology. His long and lens lectures at Columbia University in New York and in Washington in December 1905 aroused such an interest that the Carnegie Institution at once assigned the funds needed to enable him to complete and publish the applications to meteorology of the methods of analysis given in detail in Bjerknes' Vorlesungen (Leipzig, 1900, ii. 1902), and in his Recherches sur les champs de force atmosphériques (Stockholm, 1903). In his lectures of 1905 at Columbia University Bjerknes treated the atmosphere as a continuous hydrodynamic field of aerial solenoids and forces acting on them, to which vector analysis can be applied. This is due by Heaviside for electric and magnetic problems.

Every material point is a small spherical mass of air free to extend or contract with pressure, temperature or moisture; free to rotate about each of three moveable axes passing through its centre and to move along and revolve about three fixed axes through the centre of the earth. These numerous degrees of freedom are easily expressed in Bjerknes' notation and by his typical equations of motion. The general equation of motion in its simplest form is recognized as the fundamental "dimension controlling inertia and movement. The observed atmospheric condition at any moment is shown by a series of isodense surfaces intersecting the surfaces of equal temperature and of constant mass unit of solenoids. This field becomes either an electric, magnetic or hydrodynamic field according to the interpretation assigned to the notations—in each case the analytical process is the same. The analogous sets of phenomena are completely thorough, and those of one field elucidate or illustrate those of the two other fields. This is the outcome of the study of such analogies begun by Euler, Helmholtz, Hoppe, and extensively furthered by Maxwell and Kelvin, but especially by C. A. Bjerknes. The homologies or analogies by V. Bjerknes are given at p. 122 of his Recherches (1905), and include the following six tables:

I. Hydrodynamics velocity of unit mass
   - Magnetics magnetic induction
   - Electrics electric induction

II. Hydrodynamics intensity of the field
   - Magnetics
   - Electrics

III. Hydrodynamics velocity of energy
   - Magnetics magnetic induction
   - Electrics electric induction

IV. Hydrodynamics velocity of expansion per unit volume
   - Magnetics density of the true magnetic mass
   - Electrics electric induction

V. Hydrodynamics density of the dynamic vortex
   - Magnetics steady magnetic current
   - Electrics magnetic induction

VI. Electrics speed of permeability
   - Magnetics electric permeability
   - Electrics dielectric constant

These analogies have been slightly rectified by Dr G. H. Ling, Am. Jour. Math. (1908). In the application of Bjerknes' methods of study to the earth's atmosphere it is often more enlightening to express meteorological relations as analogues to phenomena in the earth's atmosphere, so that there may be a parallelism without any direct connection between the two.

The following is an extract from a paper published in the Annals and Reports of the U.S. Geol. Survey, 1908:

"... For a long time attempts were made to explain the periodic variations of the barometer by a consideration of static conditions, but it is now evident that this problem, like that of the circulation of the atmosphere, is of a dynamic nature, and that a series of researches into the character of the phenomena from an observational point of view has been made by Hahn, who gave a summary of our knowledge on the subject in the Jour. Rech. Geophys. (1902) and in the Quart. Jour. Roy. Met. Soc. (Jan. 1899) (see also an important addition by Hahn and Trabert in the Met. Zeit, Nov. 1899, and the summary of his results as given in the Jour. Rech. Geophys. 1902). Hahn has shown that at the earth's surface three regular periodic variations are established by observation, viz. the diurnal, semi-diurnal and ter-diurnal. On the higher mountains these variations change their character with altitude. (1) At the equator the diurnal variation is represented by the formula $\sin (5 + 2\pi x)$, where $x$ is the local angle of the sun. In higher latitudes either north or south the coefficient $A_2 = 0.30$ mm. diminishes, so that the phase as well as the amplitude decreases. It is therefore evident that this diurnal oscillation depends directly on the hour angle of the sun, and probably, therefore, principally on the amount of heat and vapour received by the atmosphere from the earth as a function of the sun's position in the year. It is apparently but little affected by the wind, but somewhat by altitude above sea; the amplitude diminishes to zero at a certain elevation, and then reappears and increases with the opposite sense, the phase angle not changing. (2) Semi-diurnal oscillation is larger semi-diurnal one, which goes through its maximum and minimum phases twice in the course of a day. The amplitude of this variation is largest in equatorial regions, and is expressed by the formula $A_2 = 0.988 \sin (2\pi x) - 0.573 \sin (2\pi x)$, as given by Hahn, or $A_2 = 0.992 \sin (2\pi x) - 0.495 \sin (2\pi x)$, as revised by Trabert. This amplitude also may be considered as the sum of two diurnal components, each having its maximum and minimum phases at certain central meridians. The times at which the semi-diurnal phases of maximum and minimum occur are subject to laws different from those for the diurnal period. Within the tropics the phase of the semi-diurnal period is the same everywhere, and the amplitude varies slightly with the change in altitude. Beyond the tropics the semi-diurnal period is the same everywhere except near the equator. The amplitude increases, and the phase angle does not change. (3) Ter-diurnal variation is a larger semi-diurnal one, which goes through its maximum and minimum phases three times in the course of a day. It is probable that this variation is dependent on the same causes as the semi-diurnal, and is thus established by the wind, but only slightly by altitude above sea; the amplitude diminishes to zero at certain elevations, and then reappears and increases with the opposite sense, the phase value changing from day to day.

The physical of the atmosphere has not yet been explored so exhaustively as to explain fully these three systematic barometric variations, and it is not possible to investigate such a complex problem, using equations of forces, with which the existence of such variations has been proved. Among the many methods of action that have been suggested in connexion with the barometric variations the most important is that of the so-called "Barometric Oscillation."

Laplace and others have applied this investigation on the tide-generating term to the earth's atmosphere, and have shown that there is a remarkable dependence between the barometric variations and the gravitational tide of the ocean, and that when he passed to the corresponding solar and lunar gravitational tides the difference in the terms which occur in these two relations is very slight. However, the theory that the solar and lunar terrestrial gravitational tides may be the cause of the diurnal and semi-diurnal oscillations of the barometer is not yet established. The phase angle is determined by the atmosphere, and it is not impossible that the diurnal and semi-diurnal oscillations of the barometer may be due to the expansion of the lower layer of air on the illuminated half of the globe. The law of these tidal influences have been investigated by Kelvin, Rayleigh, etc.

The solar and lunar gravitational tides have been investigated by Kelvin, Rayleigh, etc.
Mag. Feb. 1890), and especially by Margules (Vienna Sitz. Ber. 1890–1893). The two latter have shown the truth of a proposition enunciated by Kelvin in 1862, without demonstration, to the effect that for a relatively small number of hours, the condensation by free rise or of cloud- or snow-producing force will have an amplitude that is larger for the half-day term than for the whole-day term. They therefore explain the expression of moisture in the atmosphere and the expression of snow or rainfall, not as simple pressurals or waves of expansion, originally produced by solar heat, but magnified by the resonance between forced and free waves in an atmosphere and on a globe having the specific dimensions of the earth. The analytic scheme is almost the same as that of Kelvin and Arrhenius, and Kelvin arrived at this special solution of the tidal equation were trigonometric functions of time, although a nearly correct result was attained by Laplace in his investigation, yet his methods as presented in the Mécanique céleste seem to have been abandoned. The Kelvin theory as a process by which a diurnal temperature wave produces a semi-diurnal pressure oscillation, as explained by Rayleigh and Margules, may be stated as follows: The diurnal temperature wave having a twenty-four hours period is the generating force of a diurnal pressure tide, which is essentially a forced and small oscillation. The natural period of the free waves in the atmosphere agrees much more nearly with twelve than with twenty-four hours. In so far as the forced and the semi-diurnal waves are reinforced far more than the other, so that a very small semi-diurnal term in the temperature oscillations will produce a pressure oscillation which is as near as possible the diurnal period. These reinforcements, however, depend upon the elastic pressure within the atmosphere, just as does the sound of a cavity. If the prevailing barometric pressures were slightly increased, the atmosphere would have the character of a liquid, and the wave of temperature could be so perfect that the barometric wave would increase to an indefinite extent. For the actual temperatures the periodicity of the free wave is about thirteen hours, or somewhat longer than the forced wave of temperature, so that the barometric oscillation does not become excessive. It would seem that we have here a suggestion to the effect that if in past geological ages the average temperature of the earth were lower, or the atmosphere was more dense, then the pressure waves could have been large enough as to produce remarkable and perhaps disastrous consequences, involving the loss of a portion of the atmosphere. A modification of this idea of resonance is proposed by Dr. William P. Zei[, 1897], but the general truth of the Kelvin-Margules-Rayleigh theorem still abides.

The Thermodynamics of a Moist Atmosphere.—The preceding section deals with the atmosphere of an incompressible gas, and therefore with simple pure hydrodynamics. If now we introduce the conception of an atmosphere of compressible gas, whose density increases with altitude, so that rising and falling currents change their temperatures by reason of the expansion and compression of the masses of air, we take the first steps in the combination of thermodynamic and hydrodynamic conditions. If we next introduce moisture, and take account of the fact that it actually exists, we have to deal with a number of cloud and rain that correspond more nearly to those which actually occur in meteorology. This combination has been elucidated by the works of Espy and Ferrel in America, Kelvin in England, Hertz and von Bezold in Germany, and by Brillouin in France. A general review of the subject will be found in Professor Bigelow's report on the clouds, since Mein, Fischer and Juhlin have been able to show "On the Thermodynamics of the Atmosphere" (Monthly Weather Review, 1896-1899).

The proper treatment of this subject began with the memoir of Kelvin, and the following equilibrium cases (Phil. Trans. Manchester Phil. Soc. 1861). The most convenient method of dealing approximately with the problems is graphic and numerical rather than analytical, and in this field the pioneer work was done by Hertz, who published his results in a memoir which was read before the Imperial Academy of Sciences in Berlin on April 18, 1884. He considers the adiabatic changes of a kilogram of mixed air and aqueous vapour, the proportional weights of each being $\lambda$ and $\mu$, respectively. In a subsequent elaborate treatment of the cases, Kelvin and von Bezold for the years 1888 and 1899, the formulae and methods are arranged so as to deal easily with the ordinary cases of nature which are not adiabatic. For isothermal conditions, there is no change in the temperature, while the quantity of aqueous vapour, which, of course, may vary to any extent. Both Hertz and von Bezold consider separately four stages or conditions of atmospheric moisture: (1) that the atmosphere is saturated with condensation; (2) that the air is saturated with condensation, and that the moisture pressure is equal to the moisture pressure of the air; (3) that it is saturated with condensation, and that the moisture pressure is not equal to the moisture pressure of the air; (4) that it is saturated with condensation, and that the moisture pressure is not equal to the moisture pressure of the air. The (B) rainfall stage, both saturated vapour and liquid particles are simultaneously present. (C) The hail stage, where saturated aqueous vapour, and water, and ice, all exist in the atmosphere. (D) The snow stage, where snow or crystals, and ice, are present. The expressions aqueous vapour and ice vapour do not occur in Hertz's article, but are now more common. The altitude of freezing temperatures is shown in the following: (1) that the air is now continuously rising, while its temperature is always below freezing-point, therefore at levels above this point the air has a moisture pressure that condenses the air is supposed to pass directly over into the fluid phase; (2) that the ice, snow, or other water condenses, and that the air is now continuously rising, while its temperature is always below freezing-point, therefore at levels above this point the air has a moisture pressure that condenses the air is supposed to pass directly over into the fluid phase; (3) that the ice, snow, or other water condenses, and that the air is now continuously rising, while its temperature is always below freezing-point, therefore at levels above this point the air has a moisture pressure that condenses the air is supposed to pass directly over into the fluid phase; (4) that the ice, snow, or other water condenses, and that the air is now continuously rising, while its temperature is always below freezing-point, therefore at levels above this point the air has a moisture pressure that condenses the air is supposed to pass directly over into the fluid phase, and so on.
of snow left within the clouds must be very small, and the cloud has the delicate appearance possessed by a thin cirrus. Hertz’s original diagnosis is given by these systems of α, β, γ and δ lines, and the moisture lines. The lines show the density of the moist air at any stage of the process. The improved diagram by Neuhoff, published in 1884, is a practical application of some of the physical principles of the Earth’s Atmosphere, and its arrangements help to solve many problems suggested by the recent progress of aerological research.

In von Bezold’s treatment of this subject only illustrative diagrams are given. The atmospheric currents, drawn on the scale, are necessarily too large and detailed. He presents graphically the exact explanation of the cooling by expansion, the loss of both mass and heat by the rainfall, and the peculiar form of the descent of moist air in aforesaid winds in Switzerland and chinook winds in Montana. Even in the neighbourhood of a storm over low lands and the ocean, the warm moist air in front, after being carried up, this latter gradient is 0.004 C. per hundred metres for the dry stage, but the actual atmospheric observations give about 0.6. Apparently this difference represents primarily the latent heat evolved by the condensation of vapour, and in the actual layers, the density in part the effect of the radiant heat directly retained in the atmosphere by the action of the dust and the surfaces of the clouds. Passing from simple changes due to ascent and descent, von Bezold now investigated the results of the interchange of different masses of air, having different temperatures and humidities, or different potential temperatures. The importance of such facts was exaggerated by Hutton, while that of thermodynamic processes was maintained by Brillouin. The relative significance of the two was first clearly shown by Hann as far as it relates to the formation of rain, and further details have been considered by von Bezold. The practical tables contained in Professor Bigelov’s report on clouds, and those of Neuhoff as arranged for the use of those who follow up von Bezold’s train of thought, complete our methods of studying this subject.

A more elaborate account of the views of von Bezold, Hertz and Helmholtz was published by Brillouin in his memoir of 1868. Just as we have learned that the motions of the atmosphere are not due either to the general distribution of heat or to local influences exerted in this manner to each, and such as the difference of temperature of the air is not due either to radiation and absorption or to dynamic processes exclusively, but to both combined, so in the phenomena of cloud the precipitation is not the result of the cooling by mixture, or to the cooling by expansion, or to radiation, but is in general a complex result of all. The effect of the evaporation of cloudy particles in the production of descending cold currents has always been understood in a general way, but was first brought to prominence by Espy in 1838, and perhaps equally forcibly by Faye in 1837. Helmholtz, in his memoirs on clouds in the atmosphere, showed how contiguous currents may be produced, and also how they mix with each other and mix together at their boundary surface; but Brillouin explains how these mixtures produce cloud and rain—not heavy rains, of course, but light showers, and spits of snow and possibly hail. He begins by replacing the layers of clear air by a set of thin layers, but moving with very different velocities, their motion, relative to the earth because of the rotation of our globe, assumes a much more complicated character than that which obtains when the air has a uniform vertical motion. A vertical motion has an angular motion, and we’ve known that this is a characteristic manner in which what apparent auxiliary forces must be introduced in order to take into account this motion, and numerous meteorologists have noted the importance of this fact since that time. Ferrant described it by Ferrel. But their points of view have been very different from mine. The subjects that I desire to study are the surfaces of discontinuity as to velocity, temperature and cloudiness in one space, and not only the movements of these in the horizontal and vertical ways, but which are to be expected in other regions of different speed, and the question only for limited areas in longitude and for contiguous zones within which the movements are steady, but not necessarily uniform. But it is evident that one can learn much as to the condition of permanent or destruction of cloud, and the manner of having uniform and parallel movements. Thus simplified, the questions can be treated by elementary geometrical means, by means of which we at once rediscover and complete the results given by Helmholtz for zones of clear air and discover a whole series of new results for zones of cloudy air.” Among Brillouin’s results are the following theorems:

A. If the atmosphere be divided into narrow zonal rings, each equal to one portion completely around the globe, thus covering a narrow zone of latitude, and if each is within itself in convective equilibrium so that the surfaces of equal pressure shall be surfaces of revolution around the axis, then, on the supposition that the vertical equilibrium the angular velocity any particle of the air will vary in inverse ratio of the square of its distance from the axis of rotation, or $a_2$ is constant; that is to say, the air will not move towards the pole unless it be a very solid, but it is not the angular velocity, smaller far from the axis and greater near to it.

B. The surfaces of equal pressure are more concave towards the centre than is the surface of the globe. This is because the outer portion is the upper part of the atmosphere.

C. In a hazy, atmosphere resting upon a rotating frictionless globe divides itself into concentric rings whose angular movements may vary as we pass from the polar region to the tropical region; the central globe rotates more rapidly than the equatorial atmospheric rings.

D. The surface of separation between two contiguous concentric rings must be such that the atmosphere pressure shall have the same value as one approaches this surface from either direction, and the surface of separation is stable if the differences of pressure in different parts of this direction are directed by the surface of the atmospheric pressure.

E. As the distribution of pressure along a line parallel to the axis of rotation is independent of the velocity of rotation, the ordinate condition of stability, viz., that the air which is lower and colder is distributed shall be maintained for this line. In general, any inclination of the surface of separation to the horizon amounting to $10^{-10}$ must be associated with very small differences of density and large differences of velocity; in practice these conditions are far exceeded.

F. If the surfaces of equal pressure or isobars are nearly horizontal, as in ordinary cases, the calculations are comparatively easy to make. Let the inclination of the isobaric surfaces be $\frac{\tan \phi}{h_1}$, where $h_1$ is the distance counted along the axis of the earth, and $h_2$ the distance measured in the direction of the attraction of gravity; then the angle of inclination of the isobaric surface is given by the equation

$$\tan \phi = \frac{h_1}{h_2} \sin \lambda$$

where $\lambda$ is the complement of the angle between the direction of gravity and the line drawn to the pole, or the axis of rotation of the earth. The surface of separation is that over which the pressure is the same in two contiguous mass zones or isobars, and is identical with a vertical plane only when the densities and velocities in the two layers have certain relations to each other. It can never lie between the isobaric surfaces that Brillouin designates as 1 and 2.

In order that the equilibrium may be stable, it is necessary that when ascending in the atmosphere along a line parallel to the polar axis of rotation the atmosphere be crossed at least in the middle of any zone there cannot exist another zone of limited altitude; it must extend upwards indefinitely. Whenever there is any zone of limited altitude it must necessarily have, near its highest or lowest part, a different inclination of the surfaces of separation from that of two or more neighbor zones. In other words, the surfaces of separation of the three zones, of which one is limited and the other two are unbounded, if there is an equilibrium for any region, very much as in the problem of the equilibrium of thin films.

G. When the contiguous zones are cloudless the mixtures take place under the following conditions: Starting from the stable conditions, the cloudless mixture ascends on the polar side when the west wind which prevails on the equatorial side of the surface of separation is warmer, and descends between the pole and the equatorial side of the horizon when the west wind which prevails on the equatorial side of the surface of separation is colder. The mixtures of cloudless air rapidly occupy the whole height of the two layers that are mixing. When they form along a surface that becomes unstable by the action of friction, a vertical whirlwind is produced. The layer of air that is warmer in the lower layer is the one that possibly corresponds to the formation of water-spouts and tornadoes.

H. When the contiguous zones are cloudy the mixtures produce decided condensations, and sometimes even precipitation, the study of these must follow closely in the train of thought followed out by von Bezold. When the contiguous winds are feeble, but the wind in the middle of the two layers is very strong, then the position of the mixture can be inverted by condensation, since the influence of difference of pressure becomes predominant. At the equator, whatever may be the difference of temperature, a zone of separation is stable. The condensation increases by the expansion, each zone of mixture being an outburst of ascending cumuli. At the equator, whatever may be the difference of
temperature, a mixture accompanied by condensation always descends when the surface of separation is unstable; moreover, the adiabatic compression rapidly evaporates the mixture.

In the last three chapters of his memoir, Brillouin applies these principles and other details to almost every observed variety of mixtures due to the pressure of one current of air against another. Fig. 11, prepared for the U.S. Monthly Weather Review (Oct. 1897), gives five of the cases elucidated by Brillouin. In each of these the left-hand side of the diagram is the polar side, the air being cold above and the wind from the east, while the right-hand side is the equatorial side, the air being warm above and the wind from the west. The reader will see that in each case, depending on the relative temperatures and winds, layers of cloud are formed of marked individuality. As none of these clouds appear in the International Cloud Atlas or the various systems of notation for clouds, one is all the more impressed with the importance of their study and the success with which Brillouin has opened up the way for future investigators. We have no longer to do with personal and local experience, but with an analytical description of a small number of characteristics easy to comprehend and applicable at every locality throughout the globe. From a thermodynamic point of view the most important study is that published by Margules, Über die Energie der Stürme (Vienna, 1905). This work considers only the total energy and its adiabatic transformations within a mass of air constituting a closed system. Truly adiabatic changes in closed systems do not occur within any special portion of the earth's atmosphere, neither can our entire atmosphere be considered as such a system—but Margules' results are approximately applicable to many observed cases and complete the demonstration of the general truth that we must not confuse our studies to the simpler cases treated by Laplace, Reiss, Schacke, Peslin, Ferrel, Mohn. All imaginable combinations of conditions exist in our atmosphere, and a method must be found to treat the whole subject comprehensively and rigorously.

The three equations of energy on which Margules bases his work are:

\[ R+\frac{8}{3}(K+P)+\frac{4}{3}A=0 \]
\[ R+\frac{K+P}{3}+\frac{4}{3}I=0 \]

where \( R \) = energy lost by friction or converted into heat; \( K \) = kinetic energy due to velocity of moving masses; \( P \) = potential energy due to location and gravity and pressure heat; \( A \) = work done by internal forces when air is expanding or contracting; \( I \) = internal energy due to the existing pressure and temperature; \( Q \) = quantity of heat or thermal energy added or lost during any operation and which is zero during adiabatic processes only.

These equations are applied to cases in which masses of air of different temperatures and moistures are superposed and then left free to assume stable equilibrium. It results in every case that there is no free energy developed. Any condensation of moisture by expansi

In our fig. 1 above given, Cottier has assumed \( n = 1.2 \), but as the values have now been computed for all altitudes from the observations given by balloons and kites, and have a very general importance and therefore we copy his work.
is the ultimate step in the formation of cloud. The cloud consists, like fog, of extremely small particles, so light that they float in the air, and it is not surprising that these particles have grown to be large and heavy to be any longer sustained by the air—that is to say, their rate of fall through the air is greater than the ascending component of the air in which they float. The process of condensation, or the formation of the drops of water or ice that constitute a cloud has not yet been satisfactorily explained. It is probable that either one of several processes contributes to bring about this result and that all of these processes together. The following paragraphs represent the hypotheses that have marked the gradual progress of our knowledge:

A. The particles of cloud may be driven together by the motions imparted to them by the wind, and may unite, and finally unite, to form large ones, which, as they descend more rapidly, overtake the smaller ones and grow into rain-drops.

B. The particles on the upper boundary of a cloud may at night-time, or in the shade, cool more decidedly than their neighbours by radiation, and thereby expanding and cooling, the supersaturation must increase until the formation takes place, in which process the water vapour and the cloud particles within a comparatively large sphere are instantaneously gathered into a large drop. The electricity that may be developed in this process may give rise to the lightning flash, instead of the reverse process described in the preceding paragraphs (C and D).

C. Some cloud particles may be supposed to be electrified positively, and others negatively, causing them to attract each other and unite into larger ones, or, aged to produce electrical effects and others charged, which may also bring about attraction and union.

D. When any violent agitation of the air, such as the sound waves due to thunder and lightning, or to other explosions, set up a current in motion, they may be driven together until brought into contact, and united into larger drops.

E. The air—or, properly speaking, the vapour—between cloud and rain is, within the cloud, generally in a state of supersaturation; but if it is steadily rising to higher altitudes, thereby expanding and cooling, the supersaturation must increase, and the process of condensation must be completed, as in the preceding way, and a sudden violent condensation takes place, in which process both the vapour and the cloud particles within a comparatively large sphere are instantaneously gathered into a large drop. The electricity that may be developed in this process may give rise to the lightning flash, instead of the reverse process described in the preceding paragraphs (C and D).

However, the preceding five hypotheses have seemed to be, it must be confessed that no one has ever yet observed the precipitation actually formed by these processes. The laborious observations of C. T. R. Wilson of Cambridge, England, probably give us the correct idea as to the molecular particles involved in the formation of rain. After having followed up the methods inaugurated by Aitken showing that the particles of dust floating in the air, no matter of what they may be composed, become, by preference the nuclei upon which the moisture begins to condense when air is cooled by expansion, Wilson then showed that in absolutely dustless air, having therefore no nuclei to facilitate condensation, there is no event when the air cooled to less than 3.5° below the dew point extent than in the case of the presence of dust; in fact, dustless air requires to be expanded more than dustless air in the ratio of 4 to 3, or 1.25 times more. The amount of this larger expansion may vary somewhat with the latitude, the temperature and the moisture. But remarkably, still he showed that dustless air, having no visible or probable nuclei, acquired such nuclei when a beam of ultra-violet light, or a flash of lightning, or the ultra-violet, or of ordinary sunlight (which possibly contains all of these radiations), was allowed to pass through the moist air in his experimental tube. In other words, these rays produce a change in the mixed gas and vapour similar to the formation of nuclei, and condensation of aqueous vapour takes place upon these invisible nuclei as readily as upon the visible dust nuclei. Further, the presence of certain metals within the experimental tube also produces nuclei; but the amount of expansion, and therefore of cooling, required to produce upon these metallic nuclei is rather larger than in the case of dust nuclei. The nuclei thrown into the experimental tube by the dust or by ultra-violet light from a powerful ultra-violet wire produced by the ultra-violet, rays of an atmosphere of smoke by means of expansions slightly exceeding those required for ordinary dust. Finally, Wilson has been able to show that when dust is present it is electrified negatively in tendency to condense upon themselves as nuclei is much greater than when they are electrified positively, and he suggests that the descent of the rain-drops to the ground, carrying negative electricity from the atmosphere, may account for the phenomenon. In all cases, it explains the negative charge of the earth and the positive electricity of the atmosphere.

At this point we come into contact with the views developed by J. J. Thomson on the nature of electricity and the presence of negative and positive electricity in the atmosphere. According to him, "The molecules made up of what chemists call atoms must be still further subdivided, and the atoms must be conceived as made up of a number of particles of an electric charge, the same as the mass of the negative ion in a gas at low pressure. In the normal state, the assemblage of corpuscles forms a system which is electrical and neutral. Though the individual corpuscles behave like negative ions, yet when they are assembled in a neutral atom the negative effect is balanced by something which causes the space through which the corpuscles are spread to act as if it had a charge of positive electricity equal in amount to the sum of the negative charges on the entire system and so sufficient to overcome the repulsion of some of the atoms of the gas, resulting in the detachment of a corpuscle from such atoms. The detached corpuscles behave like negative ions and are electrified negatively in degree which is sufficient to overcome the repulsion of the lightest of the lightest in the atoms. But the atom also is characterized by the fact that it is the result of the tendency of the negative ions to change their relative positions in the eye, and the association of the positive and negative charges. But the evidence seems to be in favour of the view that not more than one corpuscle can be detached from any one atom. Now the ions by virtue of their negative charges act as nuclei around which may gather up the wetter drops of water in the gas suddenly expanded. . . . C. T. R. Wilson has shown that they require a considerably greater expansion to produce a cloud in dust-free air on the negative ions than on positive ones, when the ions are produced by Bunsen rays." It would therefore appear that the earth's atmosphere above us may, through the action of sunlight or the lightning flash as well as by other means, become ionized. The negative ions attract moisture to themselves more readily than the positive; they grow to be larger drops, and descend to the earth with their negative charges give it negative electricity, while the atmosphere is left essentially either positive or neutral. (See also ATMOSPHERIC ELECTRICITY.)

IV.—COSMICAL METEOROLOGY

Under this title have been included all possible, plausible or imaginary relations between the earth's atmosphere and intercosmic space. Among these, there is communication to and fro at the outer limit of the atmosphere, the bombardment by ions from the sun, the explanation of auroral lights and of meteoric storms, the influence of shooting stars and comet tails, the relation of the zodiacal light and the Gegen schen to the atmosphere, the parallelism between terrestrial phenomena and the variations of the solar spots and protuberances, the origin of long or short climatic periods, the cause of special widespread cold days, the existence of lunar or solar gravity tides analogous to oceanic tides, the influence of changes in the earth's orbit, the earth's axis of rotation, and all are grouped under cosmical meteorology.

But, in the writer's judgment these matters, while curious and interesting, have no appreciable bearing on the current important questions of atmospheric mechanics. There seem to be many widespread delusions and mistakes in regard to these problems, analogous to the popular errors in regard to astrology, and it is hardly necessary to do more than allude to them here. The leading meteorologists have relegated such questions to the care of theoretical astronomers and physicists who have no time to study atmospheric mechanics. The difficulty, the earth does come under other influences than that of the radiation from the sun; but in the present stage of dynamic meteorology we consider only this latter, and, assuming it to be constant as regards quantity and quality, we find the variable selective absorptions and reflections within our own atmosphere, its complex internal mechanism afford us a bewildering maze of problems such that so long as these are unsolved it would be folly to spend time on those.

V.—METEOROLOGICAL ORGANIZATIONS

During the latter half of the 19th century the prosecution of work in meteorology gradually passed out of the hands of individuals into the control of large national organizations. This was the natural result of the discovery that, by the spread of the electric telegraph and ocean cables, it had become possible to compile daily weather maps for large portions of the world and make predictions of the weather and the storms for a day or two in advance, of sufficient accuracy to be of the greatest importance to the material interests of civilized nations. The development of wireless telegraphy since 1900 has even made it possible for isolated ships at sea to exchange weather telegrams, compile daily maps and study surrounding storms. One by one every civilized nation has established either a weather bureau or a meteorological office, or a bureau of hydrography and marine meteorology, or an elaborate establishment for aeronautical explorations according to its special interests demanded. These governmental bureaus usually pursue both climatology and theoretical meteorology in addition to their daily practical
METER, ELECTRIC

work of telegraphy, forecasting, and publication of charts. Although, of course, in most cases, the so-called practical work absorbs the greater part of the labours and the chemistry; yet everywhere it is recognized that research and the development of a correct theory of the motions of the atmosphere are essential to any important progress in the art of forecasting. Among other important general works in which the official weather bureaux have united, we may enumerate the International Meteorological Congresses, of which the first was held in 1873 at Brussels, the second in 1875 at Vienna, and others more frequently since that date; the establishment of an International Com-
mmittee, to which questions of general interest are referred; the numerous series of monographs the political and logical and the general extension of the meteorological services to include terrestrial magnetism as an essential part of the physics of the globe; the systematic exploration of the upper atmosphere by means of kites and balloons; and the universal co-operation with the U.S. Weather Bureau in the contribution of simultaneous data for its international bulletin and its daily map of the whole northern hemisphere. The hydrographic offices and marine bureaux of the principal commercial nations have united so far as practicable in the daily charting of the ocean; and the political and logical and the establishment of the hydrographic and meteorological services in the years 1882 and 1883; the general extension of the meteorological services to include terrestrial magnetism as an essential part of the physics of the globe; the systematic exploration of the upper atmosphere by means of kites and balloons; and the universal co-operation with the U.S. Weather Bureau in the contribution of simultaneous data for its international bulletin and its daily map of the whole northern hemisphere.

The development of meteorology, in both its scientific and its practical aspects, is intimately dependent upon the progress of our knowledge of physics, and its study offers innumerable problems that can be solved only by proper combinations of mathematical theory and laboratory experimentation. The professors in colleges and universities who have hitherto lectured on this subject have not failed to develop some features of dynamic meteorology, although most of their attention has been given to climatology. In fact, many of them have been engrossed in the study of general problems in molecular physics, and could give meteorology only a small part of their attention. The early textbooks on meteorology were frequently mere chapters on sections of general chemistry, or chemistry and their physical aspects, and the early cases of university professors devoted to meteorology are those of the eminent Professor Heinrich Wilhelm Dove at Berlin, Professor Adolphe Quetelet at Brussels and Professor Ludwig Friedrich Kaemtz at Halle and Dorpat. In modern times we may point to Professor Wilhelm von Bezold and George Hellmann at Berlin, Professor Julius Hann at Vienna and Gratz, Professor Josef Maria Peintner at Linz and Vienna, Professor Alexander Woelkof at St Petersburg, Professors Hugo Hildebrand-Hildebrandson at Upsala, Henrik Mohn at Chris-
tania, Elias Loomis at New Haven, Connecticut, W. M. Davis and R. de C. Ward at Cambridge, Massachusetts, Alfred Angot and Marcel Brillouin at Paris, Hugo Hergesell at Strassburg, Arthur Schuster at Manchester, Peter Polis at Bonn, and Richard Börnstein at the School of Agriculture in Berlin. With these exceptions the great universities of the world have as yet given but little special encouragement to meteorology; it has even been stated that there is no great demand for higher education on the subject. On the other hand, the existence of thousands of voluntary observers, the profound interest in the weather actually taken by every individual, and the numerous schemes for utilizing our very limited knowledge of the subject through the activities of the large weather bureaux of the world demonstrate that there is a demand for knowledge perhaps even higher than the universities can offer. It would be very creditable to a nation or to a wealthy patron of science if there should be established meteorological laboratories in connexion with important universities, at which not only instruction but especially investigation might be pursued, as is done at the magnificent astronomical observatories that are so numerous throughout the world. Every atmospheric pheno-
mmon can be materially elucidated by exact laboratory experiments and measurements; theory can be confronted with facts; and the student can become an original investigator in meteorology.

The great difficulties inherent to meteorology should stimulate the devotion of the highest talent to the progress of this branch of science. The practical value of weather predictions justifies the expenditure of money and labour in order to improve them in every detail.

1. History.-Those who desire recent additions to our know-
ledge should consult first Hann's Lehrbuch der Meteorologie (4th edition, Leipzig, 1890) as a systematic encyclopaedia. Of equal importance is the Meteorologische Zeitschrift (Berlin and Vienna, 1866 to the present day). Of the works of modern meteorologists, the Journal of the Royal Meteorological Society (London) and the Monthly Weather Review (Washington) are the works most con-
venient to English readers and abound with references to current literature. The Physical Review Science Abstracts and the Fort-
schritte der Physik contain short notices of all important memoirs and will serve to direct the student's attention toward any special topic that may interest him.

2. MEASURING DEVICES.-The public supply of electric energy for lighting and power it is necessary to provide for the measurement of the electric energy or quantity by devices which are called electric meters. Those in use may be classified in several ways: (i) according to the kind of electric supply they are fitted to measure, e.g. whether continuous current or alternating current, and if the latter, whether monophase or polyphase; (ii) according to whether they record intermittently or con-
tinuously; (iii) according to the principle of their action, whether mechanical or electrolytic; (iv) according to the nature of the measurement, whether quantity or energy meters. The last classification is fundamental. Meters intended to measure electric energy (which is really the subject of the sale and purchase) are called joulé meters, or generally watt-hour meters. Meters intended to measure electric quantity are called condum meters and also ampere-hour meters; they are employed for the measurement of public electric supply on the assumption that the electromotive force or pressure is constant. Most of the practical meters in use at the present time may be classified under the following five heads: electrolytic meters, motor meters, clock meters, intermittent registering meters and induction meters.

Electrolytic Meters are exclusively ampere-hour meters, measuring electric quantity directly and electric energy only indirectly, on the assumption that the pressure of the supply is constant. The first electrolytic house meter in connexion with public electric supply was invented by S. Sprague and R. T. Sprague and T. A. Edison, the last-named inventor elaborating a type of meter which he employed in connexion with his system of electric lighting in its early days. The Edison electric meter, like those of Sprague and Lane-Fox, was based upon the principle that when an electric current flows through an electrolyte, such as sulphate of copper or sulphate of zinc, the electrodes being plates of copper or zinc, metal is dissolved off one plate (the anode) and deposited on the other plate (the cathode). It consisted of a glass vessel, containing a solution of sulphate of zinc, in which were placed two plates of pure amalgamated zinc. These plates were connected by means of a german-silver shunt, their size and the distance be-
tween them being so adjusted that about 1/10 of the current passing through the metre travelled through the electrolytic cell and 9/10 of the current passed through the shunt. Each hour's work, placed in the cells the zinc plates were weighed. The shunted voltmeter was then inserted in series with the electric supply mains leading to the house or building taking electric energy, and the cur-
rent which passed dissolved the zinc from one plate and deposited it upon the other, so that after a certain interval of time had elapsed the altered weight of the plates enabled the quantity of electricity to be determined from the known fact that an electric current of known quantity passing for a certain interval of time through a certain weight of zinc produces a certain reduction of zinc from a solution of sulphate of zinc. Hence the quantity in amper-
hours passing through the electrolytic cell being known and the fraction of the whole quantity taken by the cell being known, the quantity in amper-hours used by the shunt was calculated. To prevent tem-
perature affecting the shunt ratio, Edison joined in series with the electrolytic cell a copper cell the resistance of which increased with a rise of temperature by the same amount that the electrolyte decreased. Owing to the cost and trouble of weighing a large number of zinc plates, this type of meter fell into disuse.
A more modern type of electrolytic meter is that due to C. O. Bastian. The whole current supplied to the house flows through an electrolytic cell consisting of a glass tube containing two platinum electrodes; the electrolyte is dilute sulphuric acid covered with a layer of anode and cathode solutions. As the current flows it decomposes the liquid and liberates oxygen and hydrogen gases, which escape. The quantity of electricity which is passed is estimated by the diminution in the volume of the liquid-electrolyte. The shunt voltameter is that of A. Wright. In this meter the electrolyte is a solution of mercurous nitrate which is completely enclosed in a glass tube of a particular form. The tube is adjusted to a constant resistance, a direct current is passed through it, and the current is determined by measuring the volume of mercury delivered at the cathode. In the Long-Schattner electrolytic meter a solution of sulphate of copper is used.

Amongst motor meters one well-known type belonging to the ampero-hour species is that of S. Z. Ferranti, who introduced it in 1885. It consists of an electromagnet within the iron core of which is a permanent magnet and an electrostatic condenser. The current to be measured passes through the coils of the electromagnet, then enters the mercury disk at the centre, flows through it radially in all directions, and emerges at the periphery. The mass of mercury is thus set in motion owing to the tendency of the current to move transversely across lines of magnetic force; it becomes in fact the armature of a simple form of dynamo, and rotates with a speed which increases with the strength of the current. The rotation of the disk is measured by a pointer against a scale.

The core of the electromagnet is worked at a point far below magnetic saturation (see Magnetism); hence the field is nearly proportional to the square of the current, and the resistance offered to the rotating mercury is in consequence of the same order as the capacity of the condenser. In order to overcome the friction of the counting train, Ferranti ingeniously gave to the core of the electromagnet a certain amount of permanent magnetism. Another well-known motor meter, working on a somewhat similar principle, is due to Bastian. In this is in its improved form this meter consists of a single horseshoe permanent magnet formed of tungsten steel having a strong and constant field. Two air-gaps are made in this field parallel to each other. In one of these a copper disk, called the brake disk, revolves, and in the other a copper armature disk. The latter is slotted radially, and the magnetic field is so arranged that it perforates each half of the disk in opposite directions. The armature is immersed in a small vessel filled with mercury, which is insulated from the vessel and the armature, except at the ends of the copper slots, which are to be measured passes transversely across the disk and causes it to revolve. In the second half of the disk is a copper brake, geared on the same shaft, revolves in the field and has local or eddy currents produced in it which retard its action. The whole of the armature is so mounted as to revolve so strongly that the friction of the train becomes immaterial in comparison. This meter is an ampero-hour meter and applicable only to continuous current circuits. Another form of meter which is much used is that of Eluhl Westinghouse. It takes the form of a small dynamo having an armature and field magnets without any iron core. The armature carries on its shaft a commutator made of silver slips, and the current is led into the armature by means of brushes of silver wire. The current to be measured passes through the fixed field-coils, whilst through the armature passes a shunt current obtained by connecting the brushes across the supply magnets through a constant resistance. The dynamo is driven against a retarding force produced by the rotation of a copper disk fixed on the armature shaft, which rotates between the poles of a permanent magnet. Induced or eddy currents are thus created in the copper disk, and the reaction of these against the magnetic field offers a resistance to the rotation of the disk. When a current is passed through the meter, the armature rotates and increases its speed so strongly that the friction of the train is overcome against the retarding force due to the eddy currents in the copper brake disk. In these circumstances the number of rotations made by the armature in a given time is proportional to the product of the strength of the current flowing through the armature and the square of the field-coils, the former being the current to be measured. Hence the meter is a watt-hour meter and measures electric energy. In order to obviate the inconvenience of the train of the brake-coils are provided with an auxiliary shunt coil which supplies a driving force sufficient to overcome the friction of the counting train. This last is geared to the shaft of the brake by an endless screw, and the number of revolutions of the armature is reckoned by the counting-dials, which are so arranged as to indicate the consumption in Board-of-Trade units (1 Board-of-Trade unit = 1000 watt-hours). A modification of the above meter with some mechanical improvements has been devised by Land.

Clock Meters.—Among clock meters the best known is that of H. Aron, which is based upon a principle described by W. E. Wright and J. Perry in 1882. It can be constructed in the form of an ammepence-hour meter, but is usually the basic unit. Its principle is as follows: Suppose there are two pendulums clocks, one having an ordinary pendulum and the other having a pendulum consisting of a fine copper clock fuse; the one is placed in a cabinet containing the second clock will be either accelerated or retarded relatively to the other, since the action of gravity is supplemented by that of an electric attraction or repulsion between the two clocks which will or will not on the other. The two clock motions may be geared to a single counting mechanism which records the difference in the rates of going of the two clocks. If the difference of the number of oscillations made by the two pendulums in a given time is small compared to the number made by either of them separately, then it is easy to show that the power given to the circuit is measured by the gain or loss of one clock over the other in a given time. In this way the current can be measured, or the current-meter which can be used as either for continuous or alternating currents.

In Intermittent Registering Meters some form of ampero-meter or watt-meter registers the current or power passing into the house or running through it. These meters may be used as ampero-meter or watt-meter at definite intervals—say, every five minutes—and to add up these readings upon a set of registered dials. The arrangement therefore integrates the ampero-hours or watt-hours. These meters, of which one well-known form is that of Johnson and Phillips, have the disadvantage of being unsuited for the measurement of electric supply in those cases in which it is important to register the energy directly in watt-hours. The meter is machined up also in a form suitable for use with two or three fixed electric currents. (See Electrokinetikers.)

Requirements of a good House Meter.—A gas meter which has an error of 3% is considered to be satisfactory by the customer is not passed for use. An electricity meter should therefore have approximately the same accuracy. As a matter of fact, it is difficult to rely upon most electric meters to register correctly, it is less than 3% in full load. Out of nearly 200 current meters of various makes tested at Munich in 1902, only 319 had an error of less than 4%. The average value of the meters was 2% or 3% in full load. In a meter not on the reading of various decimal fractions of full load. Such a test is made by determining with an accurate ammeter or watt-meter the current supplied to a circuit for a period measured by a good clock and comparing with this the actual reading of the meter.

of the Christian—which attracted attention, gave them distinction, and even aroused ridicule and opposition. Wesley and his helpers, finding the Anglican churches closed against them, took to preaching in the open air; and this method is still followed, more or less, in the aggressive evangelistic work of all the Methodist Churches. As followers rapidly increased they were compelled to hold their own Sunday services, and this naturally led them to appoint local preachers to laymen possessing the gift of exhortation. These followed their ordinary avocations on week-days, but on Sundays preached to congregations in their own immediate neighbourhood, and hence were called local preachers as distinguished from travelling preachers. The extent to which the employment of the local preacher is characteristic of Methodism may be seen from the fact that in the United Kingdom while there are only about 9000 Methodist ministers, there are more than 18,000 congregations; some 13,000 congregations, chiefly in the villages, are dependent on local preachers.

In the organization adopted to foster spiritual life the very characteristic “Class-meetings for Christian fellowship” take a prominent place. Membership in the church depends solely upon being enrolled as a member of one of these meetings for Christian fellowship, and thus placing oneself under pastoral oversight.

The Wesleyan Methodists now represent the original body as founded by John Wesley in Great Britain and Ireland; but in large part they are now Methodists who have broken away from the episcopal mode of Church government after the War of Independence, and have since that time been known as Episcopal Methodists (see below). It should be noted that the Welsh Calvinistic Methodists are only slightly connected with the original body. They were indirectly the outcome of the evangelistic efforts of Howell Harris and Rowlands. Their work received the sympathy of Wesley and liberal financial help from the Countess of Huntingdon (see CALVINISTIC METHODISTS). For a time Whitefield was leader, and we find a reference to the ‘Whitefieldian and Wesleyan Methodists’ in the Supplement to the Gentleman's Magazine for 1747, p. 619. The theological views of these teachers proved quite incompatible with the Arminianism of Wesley, and a definite breach between them and him took place in 1770. The Welsh Calvinistic Methodists are now a branch of the Presbyterian Church. Other divisions have been formed at various times by secessions from the Wesleyan Methodists (see separate articles). They are: Methodist New Connexion (founded 1779-1789); Bible Christians (1815); United Methodist Free Churches* (about 1856); Primitive Methodists (founded 1737-1810); and Wesleyan Methodist Churches (about 1860); Wesleyan Reform Union (1850, reorganized 1859). These bodies have separated solely on matters of Church government and not on points of doctrine. The Primitive Methodists in Ireland were a small body who in 1817 seceded because they wished to maintain that close connexion with the Church of England which existed at the time of Wesley's death, but in 1878 they rejoined the parent body. Methodism has always been aggressive, and her children on emigrating have taken with them their evangelistic methods. (For the American branches see below.)

The statistics given in the following table (not including Junior School Classes) are from the Minutes of the Conference of the Wesleyan Methodist Church for 1909. At the death of Wesley the figures were: 313 preachers, 119 circuits and mission stations, and 76,958 members. In the United States: 97 circuits, 198 preachers and 159,000 members.

In 1837 the membership in Great Britain and Ireland was 318,716; in foreign mission stations, 66,007; in Upper Canada, 14,000; while the World Conference and churches appointed 150,678 members. Total for the world: 1,049,401, with 4478 ministers.

Three Occasional Conferences have been held—two at City Road, London, in 1881 and 1901, and one at Washington in 1894. The statistics presented at the last showed that the Church during the preceding decade had gained about a million members and three million adherents. At the same time there has been a steadily

2 These first three were joined in 1907 under the name of the United Methodist Church.
METHODOISM

growing feeling in favour of union. Canada and Australasia led the way, for in these countries the Methodist Church was undivided, and the sentiment was greatly strengthened by the formation in the United Kingdom of the United Methodist Church in 1907. See A New History of Methodism, ed. W. J. Townsend, H. B. Workman, George Eayrs (2 vols., London, 1909).

(J. A. V.)

There are in the United States sixteen distinct Methodist denominations, all agreeing essentially in doctrine. John Wesley had been conducting his United Societies for more than twenty years before the movement took root in North America.

A.—Episcopal Methodist Churches.

Philip Embury (1729-1772), a Wesleyan local preacher, emigrated in 1762 from Limerick to New York. Robert Strawbridge (1771-1781), a local preacher and native of Ireland, settled in Maryland. In 1766 Embury was stimulated by his relative, Mrs Barbara Heck, to begin Methodist preaching, and a society was soon formed, which grew rapidly. Embury was reinforced by the arrival of Thomas Webb (1724-1790), an English local preacher and a captain in the British army. Webb and Thomas Taylor, a layman of superior ability, appealed to Wesley to send over missionaries, and the 26th annual British Conference, held in 1768, sent to the society in New York $50 and furnished passage money for two missionaries, Richard Boardman and Joseph Pilmoor (1739-1823). Three years later Francis Asbury was sent over, and was made assistant superintendent. Meanwhile Strawbridge had been preaching with success in Maryland and in Virginia.

These "advance agents" of this spiritual propaganda brought with them Wesley's Arminian Theology. They brought also the "means of grace" on which Wesley placed the greatest stress; such as personal testimony in private and public, class and prayer meetings, watch-nights, love-feasts, the direct and fervent preaching of the Gospel and the singing of Wesleyan hymns, carried on by means of circuits and stations, exhorters,

1 Seating accommodation, 2,374,425.
2 Other preaching-places, 1,501. 3 Sunday and Thursday Schools.
4 Methodism is also represented in several European countries by Conferences and Missions affiliated to the Methodist Episcopal Church of America, and their membership is included in the figures given discipline, and Wesley, hearing of the disagreement, in 1773 appointed Thomas Rankin (c. 1738-1810) superintendent of the entire work of Methodism in America.

The First American Conference.—The first American Conference was held in 1773, and consisted of ten preachers, all of whom were born in England or Ireland. Asbury came to America to remain permanently; but Rankin, unable to identify himself with the people, to take the test or the standard in the Revolution, or to sympathize with the colonies, returned to England, as did all the English preachers except Asbury. By May 1776 there were 24 preachers and 4921 members; but in the first year of the Revolution there was a loss of 7 preachers and nearly 2000 members. The next year saw extensive revivals, in sections removed from the seat of war, which added more than 2000 to the number of members.

The preachers in the South determined upon administration of the sacraments, and a committee was chosen whose members ordained themselves and others. The Northern preachers opposed this step and for several years the Connexion was on the verge of disruption. An agreement was finally made to suspend the administration until Wesley's desires and judgment could be ascertained. He perceived that the society would disintegrate unless effective measures were speedily taken, and, aided by two presbyters of the Church of England, early in 1784 he ordained Thomas Coke (1747-1814), already a presbyter of that Church, as superintendent. He likewise ordained two of his lay preachers as deacons and elders, to accompany Coke, whom Wesley sent to America as his commissioner to establish, for the Methodist Society, a system of Church government, which should include the administration of Baptism and of the Lord's Supper. Coke above. The 1908 returns are: Bulgaria, 546 members; Denmark, 3771; Finland and St Petersburg, 1367; France, 221; Italy, 3669; North Germany, 12,886; Norway, 6054; South Germany, 11,808; Sweden, 15,430; Switzerland, 9419.

1 Western Conference only.
was furnished by Wesley with a document setting forth the grounds on which he had taken this step. Wesley also appointed Thomas Coke and Francis Asbury "to be joint superintendents over our brethren in North America." Soon after Coke and his companions arrived they met Asbury and fifteen preachers, and a special conference was called, which opened on the 24th of December 1784, in the suburbs of Baltimore, Maryland. This convention organized itself into a Methodist Episcopal Church, in which the liturgy sent by Wesley should be read, and the sacraments should be administered by superintendents, elders and deacons, these elders and deacons to be ordained by a presbytery using the episcopal form. Coke and Asbury were unanimously elected superintendents, Coke, aided by his clerical companions from England, ordaining Asbury as deacon and elder and formally consecrating him a general superintendent. Several elders were ordained. This convention adopted the first Discipline of the Methodist Episcopal Church. It adopted the existing doctrinal standards, consisting chiefly of Wesley's Sermons and his Notes on the New Testament; also twenty-five of the Articles of Religion of the Church of England, modified so as to eradicate all trace of High Church ritualism, Anglican or Roman, and the distinctive doctrines of Calvinism.

The Church thus established began its ecclesiastical career with 18,000 members, 104 travelling preachers, about the same number of local preachers, and more than 200 licensed exhorters. There were 60 chapels and 800 regular preaching places.

The energy of Asbury, and the position of Coke in the Church of England, his wealth, culture, and preaching power, greatly reinvigorated the sinewed church and enabled the administration of the sacraments brought peace; and many who would not unite with the "Society" asked admission to the Church. Within five years the number of preachers swelled to 227, and the members to 45,049 (white) and 1,168 (coloured).

To bind the whole body the existing method required the concurrence of each Annual Conference with every proposition. This was inconvenient and occasioned much loss of time; therefore a General Conference was established to meet once in four years. The first was held in 1792, and therein arose a sharp conflict. James O'Kelly (1735-1826), a Presiding Elder in control of a large district, proposed that, when the list of appointments was read in the Conference, if any preacher was not pleased with his assignment he might appeal to the Conference. The motion being lost, O'Kelly and several other preachers seceded. The Conference in 1804 limited the power of the Bishops by forbidding them to appoint any pastor for more than two consecutive years in charge of the same church. As all "travelling preachers" were eligible, without election, to seats in General Conferences, widespread dissatisfaction prevailed among the distant Conferences. The era of the steamboat and the telegraph, the administration of the sacraments brought peace; and many who would not unite with the "Society" asked admission to the Church. Within five years the number of preachers swelled to 227, and the members to 45,049 (white) and 1,168 (coloured).

The General Conference has power to make rules and regulations for the Church, subject only to restrictions which protect the Standards of Doctrine, the General Rules, the disposition of the property of the Book Concern and its income, the income of the Chartered Fund, and the right of ministers to trial before a jury of their peers, an appeal, and similar rights of the laity. By a two-thirds vote of a General Conference, and two-thirds votes of the members of the Annual Conference, and of the members of the Lay Electoral Conferences, present and voting, what is said in these "Restrictive Rules" can be altered or repealed, except that which deals with the Articles of Religion and "the present existing and established Standards of Doctrine." In the Annual Conferences the Bishop is the sole interpreter of law, subject to appeal to the General Conference. When presiding in the General Conference, a Bishop has no authority to decide questions of law, but may decide questions of order subject to an appeal to the body. The district superintendent visits each charge several times annually, presiding in the Quarterly Conference, the highest local authority in the Church, and he is expected to conserve the unity of the denomination and a regard for laws enacted by the supreme body. In the absence of a Bishop the district superintendent represents him, and may transfer any ministers within the bounds of his district.

Connexional Institutions.—The Book Concern, established in 1759, publishes the necessary devotional books of the Church, such as hymnal, discipline, theological works, religious experience, and numerous magazines and papers. The Board of Foreign Missions carries on extensive operations in Korea, China, Japan, Japan, India and Ceylon, Africa, South America, and Mexico. It assists the Methodist Churches organized in Norway, Sweden, Denmark, Finland, Germany and Switzerland, and has recently established missions in Russia and France. The Board of Home Missions and Church Extension supplies the foreign peoples domiciled in the United States with ministers of their own tongue. It assists all English-speaking churches in need of help, and secures, by gifts and time loans, the erection of church buildings, and helps in the education of the deaf and dumb. The Board for Foreign Missions and the Women's Home Missions and Church Extension supplies the foreign peoples domiciled in the United States with ministers of their own tongue. It assists all English-speaking churches in need of help, and secures, by gifts and time loans, the erection of church buildings, and helps in the education of the deaf and dumb. The Board for Foreign Missions and the Women's Home Missionary Societies. The Board of Education, with the aid of a University Senate, assists the young people to obtain education, and raises the standard of seminaries, colleges and universities. The Church, in the United States, supports 54 colleges and universities and 10 theological seminaries. The Freedmen's Aid Society is devoted to the educational needs of the negro race in the United States, in which work it has been very successful. The Sunday School Union, Epworth League, Methodist Brotherhood, hospitals, homes for the aged, deaconess homes and children's institutions are maintained by an increasing army of workers. The whole number of ministers (exclusive of foreign missions) in 1907, was 17,694; churches, 27,695; communicants, 2,884,831.
The Methodist Episcopal Church South.—After the adjournment of the General Conference of 1844, the representatives of thirteen Conferences covering the states holding slaves appealed to their constituents to determine what should be done to prevent Methodism in the South from being deprived of its influence over the whites and of the privilege, till then fully accorded, of preaching the Gospel and teaching its precepts to slaves. In 1845 a representative Convention was called; this body, with the approbation and participation of Bishop Andrew, organized the Methodist Episcopal Church South. At its first General Conference, in 1846, the senior Bishop of the Methodist Episcopal Church, Joshua Soule (1785–1867), offered himself to the Church, which accepted him in his episcopal capacity. William Capers (1790–1853) and Robert Payne (1799–1882) were elected to the Episcopacy. The Church thus founded began with 460,000 members, of which 2972 were Indians, 124,691 coloured, and 1379 traveling ministers.

A difficulty arose on the division of the property of the Book Concerns, which the Methodist Episcopal Church maintained and involved a change in the Constitution. A vote to authorize the division failed, and the Methodist Episcopal Church South, hopeless of relief, brought two suits, one against the Book Concern in New York, and the other against the Book Concern in Cincinnati. The former was decided in favour of the Methodist Episcopal Church South, and the latter in favour of the Methodist Episcopal Church. In the latter case an appeal was taken by the Methodist Episcopal Church South to the Supreme Court of the United States, which held that the Methodist Episcopal Church South was an integral part of the Methodist Episcopal Church which owned the Book Concerns, and ordered that the Southern Church should receive a proportionate part of the property of both Book Concerns. The amount ordered by the Court was due in due time.

The membership of the Church in 1850 was more than three-quarters of a million; but the Church was doomed to feel the force of the destructive elements of the Civil War. In April 1862 New Orleans was in possession of the Federal Government, rendering it impossible to hold the General Conference due at that time and place.

At the close of the war the Missionary Society of the Church was $60,000 in debt, the Publishing House practically in ruins, and of the more than 200,000 coloured members in 1860 there remained fewer than 50,000. The Conference of 1866 convened in New Orleans. Radical changes in polity were effected. Attendance upon class meetings, which, from the origin of the Church had been obligatory, was made voluntary, and the rule was enacted which required a probation of six months before admission into full membership. The time limit on the continuation of pastorates was extended from two to four years. The most radical change was the introduction into the General Conference of a number of lay representatives equal to the number of clergymen, and the admission into each Annual Conference of four lay delegates for each Presiding Elder’s district.

The coloured people, with the consent of the Church, withdrew in 1866, and formed a new Church called the Coloured Methodist Episcopal Church.

The most striking denominational effort in its history was the maintenance of the solvency of the Publishing House, which was seized by the Federal Troops, and used as a United States printing office; with the damage done, and debts incurred in rebuilding, after a fire, interest, &c., the liabilities were $35,000, with debts $125,000 in excess of assets. The concern was declared insolvent; but the necessary funds were forthcoming, and the honour of the Church was maintained.

Education has received increasing attention. The necessary titles to 175 institutions are held by the Church, and the list of colleges and their character is a credit to the denomination. The most important is Vanderbilt University, at Nashville, Tennessee, founded in 1872, and largely endowed by members of the family whose name it bears. The chief foreign missions are in China, Mexico, Brazil, Japan, Korea and Cuba. Its mission in Japan and the mission of the Methodist Episcopal Church and the Methodist Church of Canada were united in 1907 in a new organization entitled the Methodist Church of Japan. It is a practical veto power possessed by the bishops, to be exercised when the conference adopts any measure which in their opinion is unconstitutional. They have the right to present objections and, if two-thirds vote adheres to its action, the proposal is sent down to the Annual Conference for ratification; otherwise it is void. Fraternal relations between the two great Episcopal Methodist Churches were restored in 1876, and have broadened in spirit and scope from that time.

The Methodist Episcopal Church South in 1897 had 6774 ministers, 235 churches and 681864 members; in 1907, 3632 ministers and 1641086 members. The Methodist Episcopal Church, the African Methodist Episcopal Church, and the Coloured Methodist Episcopal Church, in 1907 comprised 6190 ministers, 5321 churches, and 842023 communicants.

Methodist Episcopal, Zion Church.—Some of the coloured people in the city of New York, "feeling themselves oppressed by caste prejudice, and suffering the deprivation of Church privileges permitted to others," organized among themselves, in 1866, and in the year 1866, a church and named it Zion. For twenty years the Methodist Episcopal Church supplied this church with pastors. Then the members induced three white ministers to ordain as elders three of their brethren, already deacons. Since they had neither money nor influence, they were sent upon a mission field. These proceeded to ordain others, and established churches in Philadelphia and New Hampshire. The elders ordained one of their number a bishop. As late as 1863 the Church had only 92 ministers and 5000 members, but in twelve years it doubled its membership more than five times. In this Church the sexes are equally eligible to all positions. Its educational operations at first were failures, but gradually became successful. Its foreign missions were made a separate department in 1884. This Church had, in 1897, 3871 ministers, 3266 churches and 573,107 communicants.

Coloured Methodist Episcopal Church.—In 1866 the General Conference of the Methodists in the Southern States authorized the bishops to organize its coloured members into an independent ecclesiastical body, if it should appear that they desired it. The General Conference formed a new body, called the Coloured Methodist Episcopal Church, in 1870. This Church was organized in 1870 by appointed commission and has an Annual Conference. In 1907 it comprised 6190 ministers, 5321 churches, and 842023 communicants.

The Union American Methodist Episcopal Church agrees in doctrines and usages with other Methodist bodies. It is divided into Conferences and elects its Bishops for life. It had in 1907, 18500 members, 135 ministers and 255 churches.

B.—New-Episcopal Methodist Churches.

The Methodist Protestant Church.—In 1846, ministers and laymen of the Methodist Episcopal Church began to criticize its polity, and when their utterances became aggressive the adherents to the regular order replied with equal vigour. During the General Conference of 1824, held in Baltimore, a Convention of "Reformers" met, and established a periodical entitled The Mutual Rights of the Ministers and Members of the Methodist Episcopal Church, and made arrangements to organize Union Societies. Travelling and local ministers and laymen were expelled for schism and spreading incendiary publications. Prior to the 1854 Conference those expelled, and their sympathizers, formed themselves into a new body called the Methodist Reformer. These sent memorials to the General Conference of 1858, and issued addresses to the public. After a powerful and painful discussion, the appeals of the expelled members of
Conferences were rejected. The controversy centred upon lay representation, the episcopacy and the presiding eldership.

A General Convention was held on the 2nd of November 1830, a Constitution was adopted, and a new organization was established, styled the Methodist Protestant Church. Within eight years it had accumulated 30,000 members, the majority of whom were in the South and bordering states. The Methodist Protestant Church has a presbyterian form of government, the powers being in the Conference. There is no episcopal office or General Superintendent; each Annual Conference elects its own chairman. Its General Conference meets once in four years. Ministers and laymen equal in number are elected by the Annual Conferences, in a ratio of one delegate for 1000 members. The General Conference of the Methodist Protestant Church of 1856 sent delegates to the Conference of the Methodist Protestant Church, making overtures toward an organic union, but formal negotiations have not been instituted. This Church had, in 1897, 1551 ministers, 2442 churches and 183,894 communicants.

The Wesleyan Methodist Connection or Church of America.—In the Methodist Episcopal Church slavery was always a cause of contention. In 1842 certain Methodist abolitionists conferred as to the wisdom of seceding. Among the leaders were Orange Scott (1806–1847), Jotham Horton and Le Roy Sunderland (1818–1894), who advocated, in a pamphlet, entitled The True Wesleyan, they announced their withdrawal from the Church, and issued a call for a convention of all like-minded, which met on the 31st of May 1843, at Utica, New York, and founded the Wesleyan Methodist Connection or Church of America. The enterprise started with 6000 laymen and 22 travelling ministers of the Methodist Episcopal Church, and nearly as many more from the Methodist Protestant Church and other small bodies of Methodist antecedents. Its General Conference has an equal number of ministers and laymen. In less than eighteen months the number of the Laymen had been increased, but as the Methodist Episcopal Church had purged itself from slavery in 1844, and slavery itself was abolished in 1862, a large number of ministers and thousands of communicants, connected with this body, returned to the Methodist Episcopal Church. It had in 1897 539 ministers, 609 churches and 18,587 communicants.

The Congregational Methodists originated in 1822; but in policy they are not strictly Congregational. Appeals from the decisions of the Laymen may be taken by the Ministers to the General Conference, which acts as a Court of Revision or Appeal. The ordained ministry of the Church is presbytery-organized, but as the Church is non-episcopal, no synodical organization is maintained.

The New York Wesleyan Conference held in 1859 was the result of ten years of agitation. A number of ministers and members within the bounds of the Generose Conference had withdrawn from that body in 1850, and the Conference in 1859 resulted in the withdrawal of a few members of the same Conference. The Conference in 1860, and 1861, and the last Conference in 1866, resulted in the withdrawal of a few members of the same Conference.

Methodist New Connexion, a Protestant Nonconformist Church, formed in 1797 by secession from the Wesleyan Methodists, and merged in 1897 into the United Methodist Church (p.c.).

Minor Methodist Churches.—The Primitive Methodist Church, as it exists in the United States, came from England. In 1897 it reported 7013 communicants. The Independent Methodists are composed of congregations in Maryland, Tennessee and the District of Columbia. They had fewer than 3000 members in 1907. The Evangelical Missionary Church comprises members in Ohio, who in 1886 withdrew from the African Methodist Episcopal Church, and now have less than 1000 members. The Congregational Methodists in 1881 withdrew from the Methodist Episcopal Church South, in Georgia. They had 4922 members in 1897. The Methodist Church of New York, in 1897, reported 816, and differed from the African Methodist Episcopal Church in opposing itinerancy, "paid ministers," and episcopacy. In 1897 it had 3867 members in eight states. The Zion Union Association, in 1896, had 10,900 members. The English Church of New York reported in 1890 to have 2346 communicants, and shows no gain at the present time.

Methodist New Connexion, a Protestant Nonconformist Church, formed in 1797 by secession from the Wesleyan Methodists, and merged in 1897 into the United Methodist Church (p.c.). The secession was led by Alexander Kilham (q.v.), and resulted from a dispute regarding the position and rights of the laity. Kilham and his party desired more power for the members and more self-government for the churches. Kilham and his followers withdrew, and the newly-formed church was called the Methodist New Connexion. The two bodies merged in 1897 to form the United Methodist Church.

Methodists (c. 825–885), the apostle of the Slavs, was a native of Byzantium, probably by nationality a Graecized Slav. His father's name was Leo, and his family was socially distinguished. Methodius himself had already attained high official rank in the government of Macedonia before he determined to become a monk. His younger brother Constantine (better known as Cyril, the name he adopted at Rome shortly before his death) was a friend of Photius, and had earned the surname "the Philosopher" in Constantinople before he withdrew to monastic life. Constantine about 860 had been sent by the emperor Michael III. to the Khazars, a Tatar people living north-east of the Black Sea, in response to their request for a Christian teacher, but had not remained long among them; after this he returned to the imperial court, where he married the daughter of the emperor, his brother and he worked among the Bulgarians of Thrace and Moesia, baptizing their king Boris in 861. About 863, at the invitation of Rastislav, king of "Great Moravia," who desired the Christianization of his subjects, but
at the same time that they should be independent of the Germans, the two brothers went to his capital (its site is unknown), and, besides establishing a seminary for the education of priests, successfully occupied themselves in translating in the vernacular and in diffusing their translations of Scripture lessons and liturgical contents. Some conflict with the German priests, who used the Latin liturgy, led to their visiting Pope Nicholas I., who had just been engaged in his still extant correspondence with the newly converted Bulgarian king; his death (in 867) occurred before their arrival, but they were kindly received by his successor Hadrian II. Constantine died in Rome (in 869), but Methodius, after satisfying the pope of his orthodoxy and obedience, went back to his labours in "Moravia" as archbishop of the Slavonia (Sirmium) in Pannonia. His name appears to have been, rather speaking, co-extensive with the basins of the Raab, Drave and Save, and thus to have included parts of what had previously belonged to the provinces of Salzburg and Passau. In 871 complaints on this account were made at Rome, nominally on behalf of the archbishop of Salzburg, but really in the interests of the German king and his Germanizing ally Swatopluk, Rasti- slav's successor; they were not, however, immediately successful. In 879, however, Methodius was again summoned to Rome by Pope John VIII., after having declined to give up the fragment of celebrating mass in the Slavonic tongue; but, owing to the peculiar delicacy of the relations of Rome with Constantinople, and with the young church of Bulgaria, the pope, contrary to all expectation, ultimately decided in favour of a Slavonic liturgy, and sent Methodius (880) back to his diocese with a suffragan bishop of Neitra, and with a letter of recommendation to Swatopluk. This suffragan, a German named Wiching, unfortunately proved the reverse of helpful to his metropolitan, and through his agency, especially after the death of John VIII. In 892, the closing years of the life of Methodius were embittered by continual ecclesiastical disputes, the course of which he is said to have laid Swatopluk and his supporters under theban, and the realm under interdict. The most trustworthy tradition says that Methodius died at Hardisch on the March, on the 6th of April 885. He was buried at Welehrad (probably Steuhlweisenburg). The Greek Church commemorates St Cyril on February 14 and St Methodius on May 11; in the Roman Church both are commemorated on March 9. Their canonization (by Leo XIII. in 1881) is noteworthy, in view of the fact that Gregory VII. and some of his successors condemned them as Arians. After the death of Methodius much of his work was undone; his successor Gosrad, a Slav, was expelled, with all the Slav priests, and the Latin language and liturgy supplanted the vernacular. On the 5th of July 863 a millennial celebration of the two brother apostles was held by the people of Bohemia and Moravia.

Bonwetsch, Cyril und Methodius, die Lehrer der Slaven (Erlangen, 1885), and art. in Hauck-Hertzog's Realencyc. fur prot. Theol. iv. 384, where the literature is cited; G. F. Maclear, Conversion of the Slates (London, 1873).

METHUEN, BARONY OF. The English title of Baron Methuen of Corsham (Wilts) was created in 1838 for Paul Methuen (1770–1849), who had been a Tory member of parliament for Wilts from 1812 to 1819, and then sat as a Whig for North Wilts from 1833 to 1838. His father, Paul Methuen, was the cousin and heir of the wealthy Sir Paul Methuen (1672–1757), a well-known politician, courtier, diplomatist and patron of art and literature, who was the son of John Methuen (c. 1650–1700), Lord Chancellor of Ireland (1697–1702) and ambassador to Portugal. It was the last-named who in 1723 negotiated the famous "Methuen Treaty," which, in return for the admission of English woollens into Portugal, granted differential duties favouring the importation of Portuguese wines into England to the disadvantage of French, and thus displaced the drinking of Burgundy by that of port. He and his son were both buried in Westminster Abbey. The 1st baron was succeeded in the title by his son Frederick Henry Paul Methuen (1818–1891), and the latter by his son Paul, 3rd baron (b. 1845), a distinguished soldier, who became a major-general in 1890, and general officer commanding-in-chief in South Africa in 1907. The 3rd baron joined the Scots Guards in 1864, served in the Ashanti War of 1874 and the Egyptian War of 1882, and commanded Methuen's Horse in Bechuanaland in 1884–85, and the first division of the 1st Army Corps in the South African War of 1899–1902. (See TRANSVAAL.)

METHUSELAH, in the Old Testament, the seventh in descent from Adam, and father of Lamech. According to Genesis v. 21 he lived 969 years (see BIBLE: Old Testament, § 5, "Chronology"). The name itself has been much discussed. Hitzig interprets it as "man of the javelin." Hommel prefers "man of Selah," Schah being the Hebrew form of the Babylonian Sarrahu (i.e., "god Sin"), and identifies it with the Αμήσως of Berossus. The form Methuselah, used by the author of Gen. iv. 18 and by some commentators preferred for Gen. v. 21, is variously explained as meaning "man of El" (Baal), or as a transcription (Saye) of the Babylonian Mutu-ša-ili (possibly, "man of the goddess").

METHVEN, a village and parish of Perthshire, Scotland, 7½ m. W. by N. of Perth by the Caledonian Railway. Pop. of parish (1911), 1699. Only an aisle remains of the collegiate church founded in 1433 by Walter Stewart, earl of Atholl (d. 1437). Methven, a 3rd son of the village, Methven Castle, dating partly of 1680, occupies a fine situation in a park in which stands the Pepperwill oak, 18 ft. in circumference. At Dronach Haugh near the banks of the Almond, which bounds the parish on the N., the earl of Pembroke defeated Robert Bruce in 1306. At Lynedoch, his estate on the Almond, Thomas Graham (1748–1843), the Peninsular general, afterwards Lord Lynedoch, carried on many experiments in farming and stock-breeding. He formerly owned Balgowan House, about 3 m. south-west of Methven, where many years after his death the proprietor discovered, during certain alterations, the portrait of Lord Lynedoch's wife, the Hon. Mrs Graham (a daughter of the 7th Lord Cathcart), one of Gainsborough's masterpieces, now in the National Gallery in Edinburgh in 4½ m. north-west of Methven, occupying a beautiful position in Glenalmond, is Trinity College, a public school on the English model, the first of its kind in Scotland, founded in 1841 through the efforts of W. E. Gladstone, J. R. Hope-Scott, Dean Ramsay and others, and opened in 1847. In 1851 Charles Wordsworth, the first warden, afterwards bishop of St Andrews, added the chapel. At the southern end of the village, Methven, about 3 m. south-east of Methven, Montrose won the first of a series of battles over the Covenanters on the 1st of September 1644.

METHYL ALCOHOL (C₂H₅OH), the simplest aliphatic alcohol; an impure form is known in commerce as wood-spirit, being produced in the destructive distillation of wood. The name methyl, from Gr. μιθυ, wine, ἦγος, wood, explains its origin. Discovered by Boyle in 1661, it was first carefully studied by Dumas and Péligot in 1851; its synthesis from its elements (through methane and methyl chloride) was effected by Berzelius in 1858. It is manufactured by distilling wood in iron retorts at about 500° C., when an aqueous distillate, containing methyl alcohol, acetone, acetic acid and methyl acetate, is obtained. This is neutralized with lime and redistilled in order to remove the acetic acid. The distillate is treated with anhydrous calcium chloride, the crystalline compound formed with the alcohol being separated and decomposed by redistilling with water. The aqueous product is then dehydrated with potash or lime. To obtain it perfectly pure the crude alcohol is combined with oxalic, benzoic or acetic acid, and the resulting ester separated, purified, and finally decomposed with potash. Methyl alcohol is always contained in the dry distillation of mollases. The amount of methyl alcohol present in wood spirit is determined by converting it into methyl iodide by acting with phosphorus iodide; and the acetone by converting it into iodoform by boiling with an alkaline solution of iodine in potassium iodide; ethyl alcohol is detected by giving acetylene on heating with concentrated sulphuric acid, methyl alcohol, under the same circumstances, giving methyl ether.

Pure methyl alcohol is a colourless mobile liquid, boiling at
METICULOUS—METROCLES

66°–69°, and having a specific gravity of 0.8142 at 0°C. It has a burning taste, and generally a spirituous odor, but when absolutely pure it is said to be odourless. It mixes in all proportions with water, alcohol and ether. Its compound with calcium chloride has the formula CaCl₂·4CH₃OH, and with barium oxide BaO·2CH₃OH. Oxidation gives formaldehyde, formic acid and carbonic acid; chlorine and bromine react, but less readily than with ethyl alcohol. The chief industrial applications are for making denatured alcohol (g.r.), and as a solvent, e.g. in varnish manufacture; it is also used for a fixative; a pure product is extensively used in the colour and fine chemical industries.

Methyl chloride CH₃Cl, a gas, boiling at −23°C, obtained by chlorinating methane, or, better, from methyl alcohol; wood spirit is treated with salt and sulphuric acid, or hydrochloric acid gas condensed into the boiling spirit in the presence of the evolved gas being washed with potash and dried with sulphuric acid. It is also prepared by heating trimethylamine hydrochloride. Alcohol dissolves 35 volumes and water 4. Methyl bromide is a liquid, specific gravity 1.73, boiling point 43°C; methyl iodide has a specific gravity of 2.19, and boils at 43°C.

METICULOUS (through Fr. méticuleux, from Lat. meticulus), timid, cautious; metus, fear), a term meaning pedantically or excessively careful of details, over-scrupulous, laying too much stress on minutiae.

METONIC CYCLE, in chronology, a period of 19 years during which there are 235 lunations, so called because discovered by Meton. Computation from modern data shows that 235 lunations are 6939 days, 16:5 hours; and 19 solar years, 6939 days, 14:5 hours. The relation between integral numbers of months and years expressed by Meton’s rule therefore deviates only two hours from the truth. Since 19 Julian years are 6939 hours, the relation of 235 to 19, or by only 1 1/2 hour when the Julian year is taken. Meton was an Athenian astronomer (fl. 432 B.C.).

METONYMY (Gr. μετόνυμια, change of name, from μετά denoting change, and νυμα, name), a figure of speech, in which the name of one thing is changed for that of another, to which it is related by association of ideas, as having close relationship to one another. Thus “scepter,” “throne,” “crown,” are used for royal power or authority, “hearth and home” is used for “country,” &c.

Synecdoche (Gr. συνεκδοχή, from συνεκδέχασθαι, to join in at once), a rhetorical figure similar to metonymy, in which the part is used for the whole or vice versa, thus “hands” is used for the members of the crew of a vessel; a regiment of infantry is said to number so many “bayonets,” &c.

METOPE (Gr. μετόπη, a middle space), a term in architecture for the square recess between the triglyphs in a Doric frieze, which is sometimes filled with sculpture.

METRE (μέτρον, sc. τέχνη, from Gr. μέτρον, measure), in prosody, the harmonious and regulated disposition of syllables into verse. Metrical form is distinguished from prosody by the uniformity of corresponding lines in relation to the number of syllables and the similarity of final sound (rhyme or assonance), by the repetition of certain letters at regular intervals (in alliterative measure), or merely by the regular succession of ups and downs of intonation. In ancient classic poetry the measure which creates the metrical form consists only of this last quantitative element, which is rhythm.

For the rules and divisions of the various metrical systems, see Verses. For the restricted use of "metre" as a unit of measurement, see Metric System below.

METRIC SYSTEM (adapted from Gr. μέτρον, measure), that system of weights and measures of which the metre is the fundamental unit. The theory of the system is that the metre is a part of a quadrant of the earth through Paris; the litre or unit of volume is a cube of 1/1000 metre side; the gramme or unit of weight is (nominally) the weight of a litre of water at 4°C. The idea of adopting scientific measurements had been suggested as early as the 17th century, particularly by the astronomer Jean Picard (1620–1682), who proposed to take as a unit the length of a pendulum beating one second at sea-level, at a latitude of 45°. These suggestions took practical shape by a decree of the National Assembly in 1799 appointing a committee to consider the suitability of adopting either the length of the seconds pendulum, a fraction of the length of the equator or a fraction of the quadrant of the terrestrial meridian. The committee decided in favour of the latter and a commission was appointed to make the arc of the meridian between Dunkirk and Mont Jany, near Barcelona. Another commission was also appointed to draw up a system of weights and measures based on the length of the metre and to fix the nomenclature, which on the report of the commission was established in 1795. It was not until 1799 that the report on the length of the metre was made. This was followed by the law of the 10th of December 1799 fixing definitely the value of the metre and of the kilogramme, or weight of a litre of water, and the new system became compulsory in 1801. It was found necessary however to pass an act in 1837, forbidding as and from the 1st of January 1840, under severe penalties, the use of any other weights and measures than those established by the laws of 1795 and 1799. The metric system is now obligatory in Argentina, Austria-Hungary, Belgium, Brazil, Chile, France, Germany, Greece, Italy, Mexico, Netherlands, Norway, Peru, Portugal, Rumania, Servia, Spain, Swedt, Switzerland. Its use is legalized in Egypt, Great Britain, Japan, Russia, Turkey and the United States. In 1875 there was a conference at Paris between the International Bureau of Weights and Measures, which is managed by an international committee. The object of the Bureau is to make and provide prototypes of the metre and kilogramme, for the various subscribing countries.

In England action has frequently been taken both by individuals and by the association of commercial men for the purpose of endeavours to make the metric system compulsory. A Decimal Association was formed in 1854, but did not make very much headway. A bill was introduced into parliament in 1864 to make the metric system compulsory for certain purposes, but owing to government objections a permissive bill was substituted and subsequently became law as the Metric Act 1862. It was, however, repealed by the Weights and Measures Act 1897.

See also Decimal Coinage and Weights and Measures.

METROCLES, a Greek philosopher of the Cynic school, was a contemporary of Crates, under whose persuasion he deserted the views of Theophrastus. It was his sister, Hipparchia, whose romantic attachment to Crates is a fascinating sidelight on the almost turbulent asceticism of the Cynics. He was a man of peculiar strength of character, and esteemed the joys of life so low that he was deterred from an early suicide only by the examples, which were identical with those of Crates (q.v.), he expounded by precept and example with great success, and had among his pupils
Menippus of Sinope. Having weighed the probable pains and pleasures of approaching old age, he decided that life had nothing left for which he greatly cared, and drowned himself. He is said to have written several works, which he afterwards burnt.

Of one, entitled Νεόειρ, Diogenes preserves a single line (vi. 6).

**METKODORUS,** the name of five philosophers.

1. **METKODORUS** of Athens was a philosopher and painter who flourished in the 2nd century B.C. It chanced that Paullus Aeumilus, visiting Athens on his return from his victory over Perseus in 168 B.C., asked for a tutor for his children and a painter to glaze his house. The inhabitants suggested Metkodorus as capable of discharging both duties, and it is recorded that Aeumilus was entirely satisfied (see Pliny, *Nat. Hist.* xxv. 135).

2. **METKODORUS** of Chios was an important member of the Atomic school. A pupil of Nessus, or, as some accounts prefer, of Democritus himself, he was a complete sceptic. He accepted the Democritean theory of atoms and void and the plurality of worlds, but held a theory of his own that the stars are formed from day to day by the moisture in the air under the heat of the sun. His radical scepticism is seen in the first sentence of his Περὶ φύσεως, quoted by Cicero in the *Academices* ii. 23 § 73. He says, "We know nothing, no, not even whether we know or not!" and maintains that everything is to each person only what it appears to him to be. Metkodorus is especially interesting as the teacher of Anaxarchus, the friend of Pyrrho, and, therefore, as the connecting link between atomism proper and the later scepticism. It cannot be decided whether a work entitled the Περὶ Χρόνου quoted by Athenaeus (iv. 184 a) is by this, or another, Metkodorus. The same difficulty is found in the case of the Περὶ τῶν ἀποφθέγματων referred to by the scholast in Apollonius.

3. **METKODORUS** of Lampsacus was the disciple and intimate friend of Epicurus, and is described by Cicero (de Fin. ii. 28. 92) as "almost a second Epicurus." He died in 277 B.C. at the age of fifty-three, seven years before his master, who adopted his children and in his will commended them to the care of his pupils. The wife of Metkodorus was Leontion, herself, like many other women of the time, a member of the Epicurean society. Athenaeus (vii. 279 F) quotes from the words of Metkodorus showing that he was in entire agreement with Epicurus, and was, if possible, even more dogmatic in his doctrine of pleasure. He censures his brother, Timocrates, who, though professedly Epicurean, maintained the existence of pleasures other than those of the body.

4. Another **METKODORUS** of Lampsacus was a pupil of Anaxagoras, and one of the earliest to attempt to interpret Homer allegorically. He explained not only the gods but also the heroes Agamemnon, Achilles, Hector, as representing primary elements and natural phenomena.

5. **METKODORUS** of Stratonic was a pupil, first of Apollodorus, and later of Carneades. He flourished about 110 B.C., and is reputed to have been an orator of great power. His defection from the Epicurean school is almost unique. It is explained by Cicero as being due to his theory that the scepticism of Carneades was merely a means of attacking the Stoics on their own ground. Metkodorus held that Carneades was in reality a loyal follower of Plato.

**METRONOME** (Gr. μέτρον, measure, and πόμος, law), an instrument for denoting the speed at which a musical composition is to be performed. Its invention in general but not exclusively, is ascribed to Johann Nepomuck Maelzel, a native of Ratisbon (1772–1838). It consists of a pendulum swung on a pivot; below the pivot is a fixed weight, and above it is a sliding weight which regulates the velocity of the oscillations by the greater or less distance from the pivot to which it is adjusted. The silent metronome is impelled by the touch, and ceases to beat when this impulse dies; it has a scale of numbers marked on the pendulum, and the upper part of the sliding weight is placed under that number which is to indicate the quickness of a stated note, as M.M. (Maelzel's Metronome) p=60, or ≡ =72, or ≡^2 = 108, or the like. The number 60 implies a second of time for each single oscillation of the pendulum—numbers lower than this denoting slower, and higher numbers quicker beats. The scale at first extended from 30 to 160, but now ranges from 40 to 208. A more complicated metronome is impelled by clock-work, makes a ticking sound at each beat, and continues its action till the works run down; a still more intricate machine has also been invented which is struck at the first of any number of beats, willed by the person who regulates it, and so signifies the accent as well as the time.

The earliest instrument of the kind, a weighted pendulum of variable length, is described in a paper by Etienne Louiche (Paris, 1666; Amsterdam, 1668). Attempts were also made by Embray (1722) and Gabory (1771). Harrison, who gained the prize awarded by Maelzel for his chronometer, published a description of an instrument for the purpose in 1775. Davaux (1784), Pelletier, Abel Burja (1790) and Weiske (also 1790) described their experiments for measuring musical time. In 1813 Gottfried Weber, the composer, theorist and essayist, proposed a weighted ribbon graduated by inches or smaller divisions, which might be held or otherwise fixed at any desired length, and would infallibly oscillate at the same speed so long as the impulse lasted. Stöckel and Zmeskall produced each an instrument; and Maelzel made some slight modification of that by the former, about the end of 1812, which he exhibited in London, and again in 1813. He also submitted the instrument to the difference of distance, the pendulum rocking on both sides of a centre and balanced by a fixed and a variable weight. He spent three years in completing it, and it is described and commended in the *Report of the Netherlands Academy* (1815, Aug. 14 and 18). In 1817, however, he saw Winkel and Zmeskall produced each an instrument; and Maelzel saw Winkel and inked his invention, and, recognizing its great superiority to what he called his own, offered to buy all right and title to it. Winkel refused, and Maelzel then proceeded to the invention, to which he added nothing but the scale of numbers, took this copy to Paris, obtained a patent for it, and in 1816 established there, in his own name, a manufactory for metronomes. Winkel produced a metronome, with his instrument with the same scale of numbers, and in 1816 and 1817, made a metronome in England. In 1820 Maelzel, in Amsterdam, the inventor initiated proceedings against him for his piracy, and the Academy of Sciences decided in Winkel's favour, declaring that the graduated scale was the only point in which the instrument of Maelzel differed from his. Maelzel's scale was necessarily more arbitrarily complicated, proceeding by twos from 40 to 60, by threes from 60 to 72, by fours from 72 to 120, by sixes from 120 to 144 and by eights from 144 to 208. G. Crotch constructed a time measurer, and Henry Smart (the violinist, father of the composer of the same name) made another in 1821, both before that received as Maelzel's was known in England. In 1824 James Mitchell, a Scotsman, made an ingenious and delicate pendulum clock, the inventor invented a demonstration what formerly rested wholly on the feeling of the performer.

Although "Maelzel's metronome" has universal acceptance, the simple metronome and still more Weber's graduated ribbon are generally to be preferred, for the clock-work of the other is liable to be out of order, and needs a nicety of regulation which is almost beyond all human possibility: for instance, the pendulum, which is a most subtle and sensitive part of the clock, when not in a state of rest, tends to oscillate, and to produce the same end. The movements of the instrument may be described as follows: The base and the columns are fixed, and there is a pivot with a flat surface, which is the place where the pendulum rests. This pivot is divided into many parts, which are varying distances from each other, and the distance between them is the size of the numbers. The pendulum is a thin strip of metal, cut into a circle, and divided into sections, each section having a different number of points. The points are called "beats," and are arranged at regular intervals, the distance between each point being equal to the number of the beat. The pendulum is suspended by a thread, which is attached to a small weight, called the "counterpoise," and is adjusted to the proper length. The pendulum is set in motion by a small pin, called the "trigger," which is placed against the pendulum at a certain point, and is pressed down with a certain force, which is regulated by the metronome. The pendulum is set in motion by a small pin, called the "trigger," which is placed against the pendulum at a certain point, and is pressed down with a certain force, which is regulated by the metronome.
the metropolitan is practically the same as the archbishop (q.v.); in the Eastern church he ranks above the archbishop, but below the patriarch (q.v.). Metropolitans first appear in the East in the 4th century as presiding over a province (provincia or eparchia), and their see is fixed in the principal town (μητροπόλις) of the province, which remains the normal custom both in East and West. In Africa, however, the metropolitan jurisdiction was exercised by the senior bishop (primas, primae sedis episcopus, senece for the time being, a custom which prevailed for a time also in Spain. Thus, too, in the Scottish Episcopal Church and the Protestant Episcopal Church of America there are no metropolitans, the primas being the senior bishop.

METSU, GABRIEL (1636–1667), Dutch painter, was the son of Jacob Metsu, who lived most of his days at Leiden, where he was three times married. The last of these marriages was celebrated in 1625, and Jacomma Garnijers, himself the widow of a painter, gave birth to Gabriel in 1630. According to Houbraken Metsu was taught by Gerard Dow, though his early works do not lend colour to this assertion. It is certain, however, that he was influenced in turn by Jan Steen, Rembrandt, and Hals. Metsu was registered among the first members of the painters’ corporation at Leiden; and the books of the guild also tell us that he remained a member in 1649. In 1650 he ceased to subscribe, and works bearing his name and the date of 1653 give countenance to the belief that he had then settled at Amsterdam, where he probably continued his studies under Rembrandt. One of his earliest pictures is the "Lazarus" at the Strasbourg Museum, painted under the influence of Jan Steen. Under the influence of Rembrandt Metsu turned to smaller pictures, and the "Lazarus" was the large picture with the date of 1653 in the Louvre. To the same period belong the "Departure of Hagar," formerly in the Thoré collection, and the "Widow’s Mite" at the Schwerin Gallery. But he probably observed that sacred art was ill suited to his temper, or he found the field too strongly occupied, and turned to other subjects for which he was better fitted. That at one time he was deeply impressed by the vivacity and bold technique of Frans Hals can be gathered from Lord Lonsdale’s picture of "Women at a Fishmonger’s Shop." What Metsu undertook and carried out from the first with surprising success was the low life of the market and taverns, contrasted, with wonderful versatility, by incidents of high life and the drawing-room. In no single instance do the artistic lessons of Rembrandt appear to have been lost upon him. The same principles of light and shade which had marked his schoolwork in the "Woman taken in Adultery" were applied to subjects of quite a different kind. A group in a drawing-room, a series of groups in the marketplace, or a single figure in the gloom of a tavern or parlour, was treated with the utmost fidelity by fit concentration and gradation of light, a warm flush of tone pervading every part, and, with that, the study of texture in stuffs was carried as far as it had been by Ter Borch or Dow, if not with the finish or the brio of De Hooch.

Metsu went to Amsterdam before 1655, married in 1658, and became a citizen of that city in 1659. One of the best pictures of Metsu’s manhood is the "Market-place of Amsterdam," at the Louvre, respecting which it is difficult to distribute praise in fair proportions, so excellent are the various parts, the characteristic movement and action of the dramatis personae, the selection of faces, the expression and the gesture, and the texture of the things depicted. Equally fine, though not so characteristic, is the "Sleeping Sportsman," at the Hague Gallery. His two books, "The Tabby Cat," "The Sleeping Sportsman," which cost Lord Hertford £3000, is an admirable example technically considered. Among his finest representations of home life are the "Repast" at the Hermitage in St Petersburg; the "Mother nursing her Sick Child" of the Steenraacht Gallery at the Hague; the "Amateur Musicians" at the Hague Gallery; the "Duet" and the "Music Lesson" at the National Gallery, and many more examples at nearly all the leading European galleries.

METTERNICH-WINNEBURG, CLEMENS WENZEL LOTHAR, Prince (1773–1850), Austrian statesman and diplomatist, was born at Coblenz on the 15th of May 1773. His father, Count Franz Georg Karl von Metternich-Winneburg zu Beilstein (d. 1818), was a diplomatist who had passed from the service of the archbishop-lector of Trier to that of the court of Vienna; his mother was Countess Maria Beatrix Aloisia von Kagenegg. At the time of Clemens Metternich’s birth, and for some time subsequently, his father was Austrian ambassador to the courts of the three Rhenish electors, and the boy was thus from the first brought up under the influence of the tone and ideas which flourished in the small German courts that lay within the sphere of influence of the France of the ancien régime. In 1788 he went to the university of Strassburg, where he studied German constitutional law; but the outbreak of the French Revolution caused him to leave after two years. Metternich was a witness of the excesses of the mob in Strassburg, and he ascribed his life-long hatred of political innovation to these early experiences of the victory of liberal ideas. In 1790, by way of striking contrast, he was deputed by the Catholic bench of the Westphalian college of counts to act as their master of the ceremonies at the coronation of the Emperor Leopold II. at Frankfort, a function which he again performed at the coronation of Francis II. in 1792. The intervening time he spent at Mainz, attending the university and frequenting the court of the archbishop-lector, where his impressions of the Revolution were strengthened by his intercourse with the French émigrés who had made it their centre. The outbreak of the revolutionary war drove him from Mainz, and to Mannheim, where he found employment in the chancery of his father, at that time Austrian minister to the government of the Netherlands. Here, in August 1794, he issued his first publication, a pamphlet in which he denounced the "shallow pates" of the old diplomacy and argued that the only way to combat the French revolutionary armies was by a levée en masse of the populations on the frontier of France—singular views for the statesman who was destined to be the last great representative of the old diplomacy and the greater part of whose life was to be spent in combating the national enthusiasms by which the revolutionary power of France was ultimately overthrown.

After a long stay in England, where he made the acquaintance of the prince of Wales (afterwards George IV.), Metternich went to Vienna; and on the 27th of September 1795 he married at Austerlitz theCountess Eleonore von Kaunitz, a grand-daughter of that Austrian chancellor who in many respects was his prototype. This alliance not only brought him great estates in Austria, but introduced him into the most exalted circles of Viennese society. Here he was well qualified to hold his own. "He was tall, with his hair of the same colour and texture from head to address and a certain reputation for gallantry. He was far, however, from being a mere carpet diplomatist. His interests were many and varied, and he found time for the serious study of natural science and medicine. In December 1797 he was chosen by the Westphalian counts as their representative at the congress of Rastadt, where he remained till 1799. This was his first experience of the great world of practical politics and especially of those rough diplomatists of the Revolution of whom in his letters he has left so vivid a description. In January 1801 he was appointed Austrian envoy to the elector of Cologne, and in February 1802, when the court of Dresden was mainly useful to him by bringing him into touch with the many Russian and Polish families of importance; his serious diplomatic career did not begin till his appointment, in November 1803, as ambassador at Berlin. His instructions at the outset were to

1 The family of Metternich, originally established in the county of Julich, can trace its descent to the middle of the 14th century. In 1637 they received from the archbishop of Trier the countships of Winneburg and Beilstein. These were confiscated in 1803, and the lands of the suppressed abbey of Oberlahnstein, district of prince of the Empire, were granted by the edict as compensation. The new principality was "mediatized" in 1806 in favour of Württemberg; but in virtue of their short tenure of it the descendants of Prince Metternich enjoy the privileges of mediatised princes.
prevent Prussia from joining the alliance of Russia and Great Britain against the French Republic, and to make himself agreeable to the French representative of France; but shortly afterwards his task was exactly reversed, owing to the shifting of political forces which led to the war of the third coalition, and he laboured to secure the adhesion of Prussia to the alliance of Austria, Russia and Great Britain against Napoleon. His diplomacy was not successful; for though Prussia ultimately signed the treaty of the 5th of November 1805 with Austria and Russia, the influence of the emperor Alexander and the wound given to her pride by Napoleon's contemptuous violation of her territory, had more to do with Prussia's decision than Metternich's advice, which, as the result, was the grand cross of the order of St Stephen and the appointment of ambassador at St Petersburg: but his commission to make himself agreeable to the French ambassador at Berlin was carried out to such excellent effect that, as a result of M. Lafort's reports, Napoleon requested that he might be appointed to represent Austria at the Tulleries, and in August 1806 Metternich took up his residence as ambassador in Paris.

This was the beginning of his ever growing influence in European affairs. Established in the diplomatic character of an "honourable spy" in the very centre of Napoleon's power, he used his exceptional gifts of fascination not only to become a persona grata at the Tulleries, but to establish relations with those elements in the society of the empire which were already intriguing against Napoleon's power. His intimacy with Talleyrand and with Caroline Murat, Napoleon's sister, was destined to produce notable results later. Though on the look-out, however, for any chance of weakening the French emperor's power, Metternich was not at first sanguine of success, for he believed Napoleon to be invincible. For Austria the best policy seemed to him to be to temporize; he was willing, therefore, to co-operate with France in the agreement made between Napoleon and Alexander I. of Russia at Tilisf for the partition of the Ottoman Empire; failing the success of the efforts of Austrian diplomacy to break the Franco-Russian alliance, this would at least secure for the Habsburg monarchy a share of the spoils. With the postponement of Napoleon's Oriental schemes, however, the situation was once more changed. During the summer of 1808 Metternich had reason to suspect fresh designs of the French emperor against Austria, and his suspicions appeared to be confirmed when, during an interview on the 15th of August, Napoleon indulged in one of his violent tirades, denouncing Count Stadion's action in strengthening the Austrian armaments. In November Metternich was at Vienna, urging the Austrian government to an early declaration of war—for which the moment seemed to him opportune owing to the French losses in Spain, of which he had received exaggerated reports. On the 1st of January 1809 he was back in Paris, but no longer as a persona grata. At the outbreak of the war he was placed under arrest, in retaliation for the action of the Austrian government in interning two members of the French embassy in Hungary; and in June, on Napoleon's capture of Vienna, he was conducted there under military guard. In July he was exchanged at Kómrom for the French diplomatists, and he was present with the emperor Francis at the battle of Wagram. At a council held on the 7th of July it was decided, on Metternich's initiative, to open negotiations for peace; next day Stadion tendered his resignation, which was provisionally accepted. Stadion was sent as diplomatic adviser to the headquarters of the archduke Charles, while Metternich took his place at the emperor's side. On the 4th of August Metternich was named minister of state, and soon afterwards was sent with Count Nugent to the peace conference at Altenburg, where Chamagne attended as Napoleon's representative. The conference, however, dragged on without result, and the emperor Francis decided to open negotiations with Napoleon direct. Count Buona was accordingly sent to Schönbrunn; the result was the guarantee issued in the treaty of Schönbrunn (Vienna), signed by Prince Liechtenstein on behalf of the emperor Francis on the 14th of October 1809. With the negotiation and signature of this humiliating instrument Metternich therefore had nothing to do, though on the 8th of October he had been definitely appointed minister for foreign affairs, an office he was destined to hold for nearly forty years.

The position of the new minister was no easy one. By the treaty of Schönbrunn Austria was reduced to the position of a second-rate power, and by secret articles undertook during the continuance of the maritime war to limit her force of all arms to 150,000 men, and to dismiss from her service all officers or civil officers born in the territories of ancient France, Piedmont or the former Venetian republic. Weak as she had become, the menace of the future seemed even more disquieting. To the south she was divided from the French dominions by the Save; to the west and north the vassal states of France, traditionally her enemies, lay along the frontier; to the east was Russia, which as the reward for her alliance with Napoleon had received a portion of East Galicia as her share of the spoils, and to all appearance was firmly established in the Danubian principalities. Austria seemed hopelessly cut off by Napoleon from any chance of re-asserting her traditional preponderance in Germany, by Russia from any prospect of obtaining compensation at the expense of the Ottoman Empire. One false move on the part of those who guided its destinies, and the Habsburg monarchy might easily have ceased to exist altogether.

The saving factor in the situation was the improbability of the alliance between Napoleon and Alexander continuing, and the immediate task of Metternich was to hasten its dissolution, while securing Austria's safety in the East by bringing about the end of the Russo-Turkish War. It was a task of extreme delicacy: for, while it might be thought that Russia's intervention in the war had thrown the emperor Alexander into the arms of France and plunged Austria into an unequal struggle for life and death with Russia on the banks of the Danube. Metternich was helped by the rapid development of the causes of disagreement between the French and Russian emperors. Early in 1810 Europe was full of contradictory rumours of war between France and Russia, of a marriage of Napoleon with a Russian grand duchess. Then suddenly came Napoleon's formal request for the hand of the Austrian archduchess Marie Louise. A proposal so nicely calculated to forward Metternich's plans was suspected of being due to his inspiration; certainly it was his influence that decided the emperor Francis to agree to an alliance which could not but be distasteful to him and was resented as a crowning humiliation by the proud aristocrats of Vienna.

On the 13th of March 1810 Metternich left Vienna for Paris in company with the archduchess. His object was to use so favourable an occasion for obtaining the abrogation of some of the more onerous articles of the treaty of Schönbrunn, and for coming to some arrangement whereby the serious inconvenience caused in Austria by Napoleon's coercion of the pope might be alleviated. His diplomacy, however, met with but slight success. His efforts to persuade Pius VII. to purchase a measure of liberty of action by concessions to Napoleon broke down on the gentle old man's refusal to traffic with his principles. From Napoleon he extracted a lame apology for the execution of Andreas Hofer, the reversal of a few sequestrations and, as a crowning grace, the abrogation of the article of the Schönbrunn treaty limiting Austrian armaments. In the matter of restoring the access of Austria to the Adriatic, Napoleon would make no concession; his answer to Metternich's representations was only commercial treaties which led to obtain a rice monopoly at Vienna. Anything further, e.g. an exchange of the Illyrian provinces for Galicia, must depend on the attitude of Austria in the forthcoming Russian war which, in an interview of the 26th of September, Napoleon declared to be now inevitable.

On the 10th of October Metternich was back in Vienna, where his presence was urgently needed. The policy of a Franco-Austrian entente was popular with the public and the army, resentful of the treacherous attitude of Russia in the late war, and the only powerful circles of the court it had scarce an adherent. Prince Metternich himself, who had acted as foreign secretary during his son's absence, favoured an understanding with Russia,
and was even believed to be intriguing to retain the portfolio of foreign affairs, which would have meant the victory of the Russian party. On the other hand, the French party were clamouring for the speedy conclusion of a definite alliance with Napoleon. By an admirably clear expose of the situation Metternich came over the emperor Napoleon to mediation. Of course, the policy of armed abstinence, which was to be the basic principle of his diplomatic action during the crisis of the coming years. An alliance with Russia, he argued, would be worse than useless; Austria would at any time obtain better terms from the tsar’s growing needs. An alliance with France would be one with “a power whose exclusive object is the destruction of the old order of things, which has hitherto found its defence in Austria.” Alone of European Powers Austria still had the possibility of choice; let her work for the preservation of peace and at the same time remain free, should war break out, to make her own terms. It would little serve Austria’s interests to become the ally of Russia, merely to serve as a barrier behind which the emperor Alexander could carry out his designs on Turkey in safety. In an interview with Count Shuvalov, the Russian agent, Metternich roundly declared that the maintenance of the integrity of Turkey was for Austria the question of supreme interest.

With the approach of the Russo-French War the situation became increasingly difficult. The partisans of a Russian alliance remained powerful and clamorous; but Metternich did not share the doubts as to the outcome of Napoleon’s invasion of Russia, which he believed would leave Austria, if she remained neutral, isolated amid a huge European confederation. To him the only safe course seemed to be to offer the French emperor substantial assistance, stipulating for some quid pro quo in the settlement to follow the war. The emperor Francis shared this view; and on the 14th of March a treaty of alliance was signed by which Austria agreed to support the French army with an army corps of 30,000 men operating from Galicia. This treaty was ratified at Vienna on the 25th of March, the day of Napoleon’s passage of the Niemen. It was characteristic of Metternich’s diplomacy that the Austrian generals in Galicia were ordered to act only on the defensive, and that the court of St. Petersburg was informed that Austria would only take part in the war as a principal should Russia force her to do so.

This cautious attitude was soon justified by the astounding developments of the Moscow campaign. When the full extent of the catastrophe that had overwhelmed Napoleon’s army became known, Metternich realized the advantageous position in which Austria lay for exploiting the changed situation. His first step was that France should commission Austria to mediate in the peace of Russia, and in England (Despatch of Otto, November 10); but, as affairs developed, this was replaced by the policy of temporizing until Austria should be in a position to intervene with decisive effect. Napoleon’s demand that Austria should raise her contingent from 30,000 to 100,000 men was, indeed, from Metternich’s point of view doubly opportune: for it enabled him to assume that the treaty of the 14th of March, which stipulated only for an “alliance limitée,” had been abrogated by Napoleon’s own act; that Austria had reopened the question of neutrality; and that, should she take part in the war, it would no longer be in a subordinate character but as a principal. “Le passage de la neutralité à la guerre,” said Metternich to the emperor Francis, “ne sera possible que par la médiation armée”; which meant in effect that Austria required time to complete her armaments. To gain this time was, during the weeks that followed, the object of his diplomacy. For this purpose he encouraged Napoleon to believe that Austria was prepared for a settlement on terms very favourable to the French emperor; with the result that Napoleon, though he would not hear of a mediation, “only not consented to, but pressed for, Austrian ‘Intervention’ (interférence).” But Metternich had made up his mind that the only chance of an immediate restoration of the Habsburg influence in Europe lay in using this opportunity for destroying or limiting Napoleon’s power, and he had already opened negotiations with the allied courts, with a view to enforcing a common agreement as to a basis of peace, when the indecisive battle of Lützen (May 2) gave him the opportunity of making his policy of mediation effective. Count Stadion was now sent to the emperor Alexander to lay the terms of peace which Austria was prepared to mediate; he was also to “agree to the Russian neutrality in Eminen-
tation on our part, in the event of the non-success of our efforts on behalf of peace.” On the 25th of March Napoleon gained another indecisive victory at Bautzen, which still further strengthened Metternich’s position; for Napoleon allowed himself to be persuaded into signing the ill-omened armistice of Pleiswitz (Polischwitz), on the 4th of June, and to become entangled in the insincere negotiations of the congress of Prague. Austria thus had time to complete her armaments. Meanwhile, on the 14th and 15th, June, were signed at Reichenbach the treaties of alliance between Great Britain, Russia, and Prussia, by which the signatory Powers agreed neither to negotiate nor to conclude treaty or truce with Napoleon except by common consent. In an interview with the emperor Alexander, Metternich now presented the terms which he proposed to offer to Napoleon, and on this basis a treaty between Austria, Russia and Prussia was agreed to, Austria contracting to put 150,000 men into the field, should Napoleon reject the ultimatum, and not to make peace without the consent of Russia and Prussia—which in effect involved that of Great Britain also.

But before this second treaty of Reichenbach was signed (June 27), Metternich went on Maret’s invitation to Dresden, where on the 26th he had the famous interview with Napoleon. The whole scene was on his part a masterpiece of Machiavelian diplomacy. The terms he offered to the emperor were so favourable that he has been denounced by every Prussian historian since as the enemy of Germany; while French historians have enlarged on Napoleon’s infatuation in rejecting them. In spite of the fact that the draft of the treaty of Reichenbach was in his pocket, he posed as the impartial “mediator,” with a leaning in favour of Napoleon, assuring the emperor “on his honour as a German count” that Austria was still “free from all engagements,” which was true only in so far as the treaty was not signed till the next day. Metternich’s object was, in fact, only to gain an extension of the armistice till the 10th of August, on which date Schwarzenberg had declared that he would be ready to take the offensive. As for the terms offered to Napoleon his acceptance of them need not hamper the plans of the Allies; for the consent of Great Britain would have to be obtained, and, moreover, Napoleon was sure beyond long to provide an excuse for fresh aggression; his rejection of them, on the other hand, would be a blow to his credit. The interview was long and stormy; Napoleon struggled vainly in the toils; in his excitement he dropped his hat, which the imperturbable Metternich did not condescend to pick up; “Napoleon,” he records in his Mémoirs, “seemed to me small.” Metternich, however, gained his immediate point; the armistice was extended to the roth of August. At midnight on that date, Napoleon not having come to terms, Metternich gave orders for the lighting of the beacons that signalled to the Austrian army in Silesia the outbreak of the war.

(Napoieon’s interview at Reichenbach, June 27) for the moment brought discord into the councils of the Allies and threatened the ruin of Metternich and his plans; but the successive defeats of Vandamme at Kulm (Aug. 28), of Macdonald at Katzbach (Aug. 29) and Oudinot at Grossbeczen (Aug. 30) completely altered the aspect of affairs; and on the 9th of September Metternich signed at Töplitz a treaty with Russia which committed Austria yet more closely to the policy of the Allies. Then followed the battle of Leipzig (Oct. 16-19) and the advance of the Allies into France. The diplomatic situation throughout the campaign was, from the Austrian point of view, one of extreme delicacy. The necessity of curbing the power of Napoleon and retaining his interest ever incapable of again overshadowing the balance of Europe was practically the only object Austria had in common with her allies. She did not
share the implacable resentment with which Great Britain pursued Napoleon; she watched with alarm the development of the ambitions of Alexander I., which threatened to substitute a Russian for a French supremacy in Europe; she was far from sympathizing with the noisy enthusiasm of the patriots of the War of Liberation for a united Germany, in which the traditional influence of the Habsburgs would be balanced or overshadowed by that of Prussia. Metternich had no wish to see the reign of Marie Louise, ousted in favour of the Bourbons, who had little reason to be grateful to Austria; still less did he desire to see on the throne of France Alexander's protégé Bernadotte, whose name was being whispered in the Paris salons as the destined saviour of his native country. But if Napoleon was to remain sovereign of France, it must be not by his own force, but by grace of his father-in-law, and hedged round with limitations which would have made him little more than the lieutenant of the Habsburg monarchy. This was the secret of the moderate terms of accommodation ostentatiously offered by Metternich to Napoleon at various stages of the campaign. From Frankfort he sent, through General de Saint-Aignan, a diplomatist on whose indiscretion he could rely, an informal offer of peace on the basis of France's "natural frontier," the Rhine, the Alps and the Pyrenees. The famous manifesto of Frankfort, issued on behalf of the Allies (Dec. 4, 1813), contained no such offer of acceptable terms; but Metternich's object was attained; for Napoleon refused to be drawn into the trap, and the French people cursed the emperor's infatuation in refusing a settlement which the whole world recognized as that of Saint-Aignan's mission, they believed would have satisfied the legitimate ambitions of France. On the other hand, Metternich did his best to oppose a too rapid advance of the allied forces on Paris, which would have played into the hands of Russia and Prussia; and it was to his initiative that the conferences of Châtillon were due. Only when the breakdown of the negotiations made it clear that Napoleon had seen through his plans, and preferred the chances of war to the certainty of ruin or of surviving only as the puppet of Austria, did Metternich join with Castlereagh in pressing upon the tsar the necessity for restoring the Bourbons. On the 1st of March 1814, he set his hand to the treaty of Chaumont, of which the immediate object was the restoration and preservation of the old dynasty in France reduced to her "legitimate frontier." In other respects, however, the treaty was a triumph for Metternich; for it laid down that at the final settlement Germany was to be reconstituted as a confederation of sovereign states, and it also did much to temper the fear of a Russian dictatorship by consecrating the principle of that concerted action of the Great Powers whose aim was the balance of international interest, which after Napoleon's fall was to govern the European system. On the 10th of April Metternich arrived at Paris, ten days after its occupation by the Allies. He was now at the height of his reputation; on the 20th of October 1813, two days after Leipzig, he had been created an hereditary prince of the Austrian Empire; he now received from the emperor Francis a unique honour: the right to quarter the arms of the house of Austria-Lorraine with those of Metternich. At the same time (April 21) the countship of Daruvar was bestowed upon him. On the 30th of May Metternich set his signature to the treaty of Paris, and immediately afterwards accompanied the emperor Alexander and King Frederick William on a visit to England. On the 18th of July he was back in Vienna, where the great congress was to meet in the autumn. The dignity of a Hungarian magnate was bestowed upon him before it assembled.

At the congress Metternich's charm of manner and great social gifts made him much personal influence; the ease and versatility with which he handled intricate diplomatic situations, too, excited admiration; at the same time he was blamed for his leaning to intrigue and finesse and for a certain calculated disingenuousness which led to an open breach with the emperor Alexander, who roundly called him a liar. In the difficult questions of Poland and Saxony the honest and conciliatory attitude of Castlereagh was of more avail in reaching an acceptable settlement than all Metternich's cleverness. If in the Italian and German questions, however, Austria's views triumphed, this was due to the foresight displayed in Metternich's diplomacy during the campaigns and to the address with which he handled the questions at issue at the congress. The complicity of Hardenberg in the treaty of Chaumont and the partition of the states of the Confederation of the Rhine with a view to detaching them from Napoleon; and he had used this opportunity to render impossible the idea of a united Germany. On the 8th of October 1813 he had signed with Bavaria the treaty of Ried, which in the event of the liberation of Germany guaranteed to Bavaria a sovereign and independent status. This instrument, which was reinforced by a secret treaty signed at Paris on the 3rd of June 1814, served as a model for similar agreements with other courts; and the principle involved was, as mentioned above, NAPLES: the treaty of Chaumont. Thus all the unionist ideas, represented at the congress by Stein, were sterilized from the outset; and the Act of Confederation embodied in the Final Act of Vienna gave to Germany exactly the form desired by Metternich as best calculated to perpetuate Austrian preponderance (see GERMANY: History). The same was true of the settlement of Italy. The question here was complicated by the treaty of alliance signed by Metternich with Murat as the price of his treason to Napoleon. But Metternich from the first had known that the treaty was but a temporary expedient; that "great Britain would recognize the will of the government of Naples"; and that sooner or later Murat himself would afford excuse enough for tearing the treaty up. Not Murat's dream of an Italy united under his own rule, but the traditional Austrian policy of possession in the north and preponderance throughout the Peninsula was Metternich's goal, and this he secured at the congress. Murat, in view of Austria's engagements, was suffered to survive for the time being; he himself shattered the alliance during the Hundred Days; and the Bourbons returned to Naples, pledged by a secret agreement to attenuate their policy to that of Vienna (see NAPLES: History).

Metternich, then, emerged from the congress of Vienna confirmed in the confidence of his sovereign, and therefore supreme in Germany and in Italy. To him had been due the marvellous recovery of the Habsburg monarchy; in spite of Gentz's lament that in the latter stages of the campaign of 1814 "Europe" had been substituted for "Austria" in his diplomacy, Metternich had acted throughout first and foremost in the interests of Austria, as he was bound to do. This, too, gives the key to his policy after 1815, the policy of using the European system to perpetuate the existing international order and the restoration of great and small monarchs. It was the treaty of the 20th of November 1815, as an instrument for ensuring the "stability" of Europe by suppressing any "revolutionary" manifestations by which the settlement made at Vienna might be endangered.

After the campaign of Waterloo and Napoleon's second downfall Metternich was again in Paris, where he co-operated with the emperor Alexander and Castlereagh in securing tolerable terms of peace for France. A few days after the signing of the two treaties of the 20th of November 1815, he left Paris for Milan, where it was arranged that he should meet the Austrian Baron von Rechberg, with whom he came to terms on certain outstanding questions between Austria and Bavaria, terms embodied in the treaty of Munich of the 14th of April 1816. During his visit to Italy, which he repeated in 1816 and 1817, Metternich could not but be impressed with the general signs of discontent with Austrian rule. Neither was he blind to the true causes of this discontent: the atrophy of the administration owing to its rigid centralization at Vienna, and the policy of enforcing Germanism on the Italians by a ruthless police system. He made half-hearted proposals for removing something of both these grievances; but his terror of revolution from below made him fearful of reforms from above. While therefore in Prussia king and ministers were labouring hard to remodel and consolidate the monarchy, Metternich did next to nothing to reform the most obvious abuses of the Austrian Empire. Yet the fault
was not wholly, or mainly, his. Sir Robert Gordon, in a letter to Castlereagh (dated Florence, July 11, 1819), gives the true reason for this attitude: "How much is it to be desired that the superior talents of Prince Metternich were more occupied with the revision and improvement of the administration of affairs in his own country. He is too enlightened not to perceive its most palpable defect... He might have courage to sacrifice himself for the institution of effective remedies, but he fears that the confiding benignity of his Sovereign might afterwards be dissuaded from the just and vigorous application of them."

(F.O. Austria. Gordon. Jan.–Dec., 1819.) Metternich's power, after all, was limited by the goodwill of his master, the emperor Francis, and Francis trusted him precisely because he seemed to share his own fanatical hatred of all change. It is this fact that seems to explain Metternich's feverish anxiety to justify his obscurantist attitude to himself and to the world. It suited him to ascribe the general discontent, of which the causes were not obvious, to the wanton agitation of the "sects" and his agents all over Europe earned their pay by supplying him with plentiful proof of the correctness of his contention. The result was well summed up in another letter of Gordon to Castlereagh (ibid. No. 26, Florence, July 12, 1819). "Nothing," he writes, "can surpass Prince Metternich's activity in collecting facts and information upon the inward feelings of the people; with a habit of making these researches he has acquired a taste for them.... The secrecy with which this task is indulged leads him to attach too great importance to his discoveries. Phantoms are conjured up and magnified in the dark, which probably if exposed to light would be seen to be rather shadow than substance, and his informers naturally exaggerate their reports, aware that their profit is to be commensurate with the display of their phantasmagoria." The judgment is instructive, coming as it does from a diplomatist in intimate touch with Metternich and in general sympathy with his views.

There was, none the less, method in this madness. Behind the agitations of the "sects" loomed the figures of the emperor Alexander and of his confidant Capo d'Istria, "the Cypriaues of Liberalism," whose agents, official or unofficial, were intriguing in every country in Europe, and not least in Italy. The factor, then, that determined Metternich's attitude was not so much a dread of revolutions in themselves as of revolutions exploited by the "Jacobin" tsar to establish his own preponderance in Europe. Metternich's object, then, in respect of the revolutionary agitations, was twofold: he wished to impress Alexander with the peril of this imperial coquetting with democratic forces; he wished to convince the "sects" that they could not rely on the tsar's support. He succeeded in both these objects during the period from the congress of Aix-la-Chapelle in 1818 to the congress of Verona in 1822.

On his way to the congress of Aix, Metternich spent a few days at Frankfurt, where his presence was sufficient to settle the difficult question of the constitution of the federal forces. It was a signal triumph. "You can have no idea of the effect produced by my appearance at the diet," he wrote exultingly to his wife, "I have become a species of moral power in Germany and, perhaps, even in Europe" (Mem. iv. 64). This self-complacency was characteristic of the man; but, if we accept his view of "morality," the boast scarcely seems exaggerated. In the main questions debated at Aix, indeed, it was Castlereagh's influence rather than that of Metternich which prevailed; the abolition of the supervision of French affairs by the committee of ambassadors was, for instance, carried against his opinion. But it was at Aix that Metternich was not only reconciled with Alexander, but laid the foundations of that personal influence over the tsar that was to bear notable fruit later; from Aix, too, where he arrived at a complete understanding with King Frederick William III. of Prussia and the Russian ministers, dates his preponderant influence in German affairs.

The outlook in Europe at the beginning of 1819 seemed to Metternich particularly gloomy. In France the ministry of Decazes was, in his opinion, under the inspiration of the Russian ambassador Pozzo di Borgo, heading straight for a new revolution; in Italy Russian agents were openly carrying on a Liberal propaganda; Germany, and notably the Prussian bureaucracy, was honeycombed with revolutionary ideas. Then came the news of the murder of Kotzebue (March 23). Metternich was in Italy at the time; but he determined at once to take advantage of this senseless crime to carry his views in the matter of muzzling the Liberal agitation in Germany. In the summer he met King Frederick William and Prince Hardenberg at Töplitz; a conference that resulted in the indefinite postponement of the Prussian constitution and in a secret agreement (Aug. 1) on the proposals to be laid before a conference of German ministers to be held at Carlsbad in the same month. The result of this were the famous Carlsbad Decrees (q.v.), by which liberty of speech and of the press was abolished throughout Germany. The Vienna conferences that followed in November and issued in the Final Act of the 15th of May 1820, was not so complete a triumph for Metternich; but his diplomacy, none the less, had succeeded in riveting on Germany the yoke of the Austrian system, which it was to bear with but partial and temporary relaxations for nearly thirty years (see Germany: History).

The year 1820 was marked by critical events which drew Metternich's attention once more from the affairs of Germany to those of Europe at large. The revolution in Spain, with which Austria had no immediate concern, interested him little; but his attitude towards it is characteristic and illuminating. The revolt that followed in Naples, however, necessitated a different attitude. Strictly speaking, it concerned Austria alone; but Metternich was anxious to range Alexander openly against Italian Liberalism, and he therefore consented to the question being laid before a congress to be assembled at Troppau. The congresses of Troppau (1820) and Laibach (1821) are dealt with elsewhere (see Europe: History; Italy: History, and the articles s. v.). For Metternich they represented a signal triumph. Not only did he complete his ascendancy over the emperor Alexander; but he openly committed all the Powers to an approval of the Austrian system in Italy, a success that outweighed his failure to win over Great Britain to the general principle of intervention, as advocated by Lord Castlereagh; the idea of the continental Alliance to prevent Alexander from acting independently of the concert. But Metternich's hope that the Greek revolt would burn itself out "beyond the pale of civilization" was belied by events; and even before Castlereagh's death it was clear that Great Britain would have sooner or later to adopt a policy of intervention opposed to all Metternich's ideas. The breach was hastened by the accession to office of George Canning, who hated Metternich and all his ways. At Verona in 1822 the withdrawal of Great Britain from the system of the continental Allies was proclaimed to all the world; in March 1823 Canning recognized the Greek flag. This opened up the whole Eastern Question in the precise form that Metternich had sought to
METTERNICH

avoid; for the action of Great Britain involved a move on the part of Russia, jealous of her prestige in the Levant, and thus led ultimately to a rearrangement of the relations of the Powers which, so far as the affairs of the Ottoman empire were concerned, left Austria isolated. It is impossible here even to outline Metternich's diplomacy during the eleven years between the outbreak of the Greek revolt and the signature of the treaty of London (1832) by which the kingdom of Greece was established. The principles that guided it are, however, sufficiently simple. In common with Great Britain he desired to maintain the integrity of the Ottoman Empire as a barrier against Russian domination in the Balkan peninsula; he wished also to avert a Russo-Turkish war, not only for the above reason, but also because this would involve the breakdown of the system by which he hoped to curb the revolutionary forces in the West. He therefore attempted, and for a while successfully, to persuade the tsar that the Greeks were only "ordinary rebels against legitimate authority." But, when this expedient failed, he was the first to suggest the complete independence of Greece, which seemed to him less dangerous to Austrian interests than a tributary principality on the model of Moldavia and Wallachia. In the end his attitude was one of abstention and protest, since he rightly considered that the action of the Powers which culminated in the treaty of London was fatal to the doctrine of legitimacy, on which his system was based.

The Greek question was not finally settled when the outbreak of the revolutions of 1830 threatened the overthrow of the whole structure of 1815 in the West. Events which seemed to involve the complete ruin of Metternich's system gave it in effect, however, a new lease of life. Austria, isolated by the events in the East, was once more brought into touch with Russia by a crisis that concerned both Powers equally. On the receipt of the news of the July revolution in Paris Metternich hastened to meet Count Nasselродe at Carlshad; and, though the Russian statesman refused to commit himself to the idea of an immediate reconstitution of a league of the three autocratic Powers, a common basis of action was agreed upon, and the foundations were laid for that cordial understanding that ripened in the meeting of Münchgrätz three years later. Meanwhile, though his language was still "European," Metternich's attitude towards the revolutions was wholly Austrian. He preached the sacred duty of intervention, but he refused to intervene, save where the interests of the Habsburg monarchy were directly concerned. He was even the first to recognize the revolutionary government of Louis Philippe (Sept. 8); he answered the appeal of the king of Holland for help with an ironical reference to the geographical situation of Austria; he did not even interfere with the two elective courts in Germany and Poland. But when in Italy revolts broke out that threatened the Austrian monarchy, he acted with promptitude and decision, in spite of the threatening attitude of France in the spring of 1831 Austrian bayonets restored order in Parma, Modena and the Papal States. Yet even here Metternich showed an unwonted moderation: not only did he soon withdraw the Austrian troops from Ancona, but he took the initiative in impressing on the papal government the urgent necessity for drastic reform. This attitude was, indeed, mainly determined by the uncertainty as to the relations of the three autocratic courts on whose cooperation the effectiveness of a policy of repression ultimately depended; and Metternich's next work was to attempt to re-cement the broken alliance. With Russia he had little difficulty; the timidity of King Frederick William III. had increased with years and the events of 1830, and the Russian and Austrian governments came to complete understanding on a common policy in Germany. Its first fruits were the additional articles appended by the Federal Diet (June 28, 1832) to the Vienna Final Act, by which the control of the censorship over the state legislatures was increased. As for Russia, Count Nasselродe at first maintained the reticent attitude he had adopted at Carlshad; but finally, in 1833, Metternich met the emperor Nicholas I. himself at Münchgrätz and by adroit flattery won him over to his views. The Berlin convention of the 15th of October 1833, which re-affirmed the divine right of intervention, was a fresh triumph for Metternich's diplomacy. This had been rendered possible by the change in Russia's attitude towards the Turkish question after 1829, which made a co-operation of Austria and Russia possible in the East (see MEHEMET ATI); and in its turn it made possible the maintenance for a while longer of the Austrian system in Germany.

The convention of Berlin marked the last conspicuous intervention of Metternich in the general affairs of Europe. "The Holy Alliance of the East," as Palmerston called it, served the immediate purpose of securing "stability" in the countries immediately subject to the Powers composing it; it made no attempt at more "moral" intervention in questions, e.g. that of Spain, that lay beyond its own sphere of influence; and the development of the Eastern Question, leading to the rapprochement between Russia and Great Britain, though Austria joined the Quadruple Alliance of 1840, tended to loosen the cordial ties between the courts of Vienna and St. Petersburg. The Straits Convention of 1841, by which France was formally readmitted to the concert, was due largely to Metternich's initiative; so, too, was the ill-judged effort of the continental Powers in 1842 to interfere in favour of the Sonderbund in Switzerland. But, on the whole, the growing crisis within the Habsburg monarchy itself was sufficient to deter Metternich from foreign adventures. So long as the emperor Francis lived all question of reform was impossible, and when he died, in 1835, the rusty machinery of the Austrian administration was too completely out of gear to be set right by anything short of revolution. The crown prince, who succeeded him, was too old to set his hand, even had he had the inclination to do so. He was too experienced not to realize the sickness of the state, but he was content to veil it from himself and to attempt to veil it from others. The world was not deceived; but it was not until the Vienna mob, in 1848, was thundering at the door of his cabinet that Metternich himself realized the truth to which he had tried to blind himself. With his fall his system also fell; and his flight from Vienna was the signal for the revolutions by which in 1848 all the countries under Habsburg influence were convulsed.

The resignation of Prince Metternich, handed in on the 13th of March 1848, was accepted by the emperor on the 18th, and the prince and his family at once left for England. Here he lived in great retirement, at Brighton and London, until October 1849, when he went to Brussels. In May 1851 he went to his estate of Johannesberg, where he was visited by King Frederick William IV. and Bismarck; in September he returned to Vienna. The events of 1848 had not shaken his self-complacency; they seemed to him rather to confirm the soundness of his own political principles, which would have scoffed the evil betimes had not the weakness of the Austrian crown prince rendered it impossible to gather strength. But though, in his own opinion, triumphantly vindicated, he did not again take office; he maintained, none the less, as a critic and adviser no mean influence on the counsels of the Austrian court, though it was contrary to his advice that Austria signed the treaty of the end of December 1854 with France and Great Britain. He lived to see the beginning of the struggle of France and Italy against Austria, dying on the 11th of June 1859.

Probably no statesman of all time has, in his own day, been more basely slandered with praise and bespattered with abuse than Metternich. By one side he was reverenced as the infallible oracle of diplomatic inspiration, by the other he was loathed and despised as the very incarnation of the spirit of obscurantism and oppression. The victories of democracy brought the latter view into fashion, and to the Liberal historians of the latter part of the 19th century the name of Metternich was synonymous with that of a system in which they could recognize nothing but a senseless opposition to the forces of enlightenment. A juster estimate of the man and his work has, however, become possible as the age has moved farther away from the smoke of controversy. On the whole, history has tended to endorse the same judgment on Metternich pronounced by Castlereagh when
he was first brought into diplomatic contact with him. Writing from Chaumont to Lord Liverpool, on the 26th of February 1814, he said: "Austria both in army and government is a timid Power. Her minister is constitutionally temporizing—he is charged with more faults than belong to him, but he has his full share, mixed up, however, with considerable means for carrying forward the machine; more than any other person I have met with at Head Quarters" (F. O. 2 France, From Lord Castlereagh). This gives the key to Metternich's character and policy: Austria was a timid Power, and Metternich was an Austrian minister. His policy of "stability," so necessary for the Habsburg monarchy, at least secured a long period of peace for Europe at large. Europe, her strength renewed, passed a severe judgment on the statesman who acted on the assumption that what the generality of people wanted was peace, not liberty; and justly, in so far as his pessimism led him to convert what might have been legitimate as a temporary counsel of expedience into an immutable principle. But, as Demelitsch points out, it will be time for Austrians to condemn him when Austria shall have survived half a century of constitutional experiment under the dual monarchy.

Of the technique of diplomacy Metternich was a master. His despachets are models of diplomatic style. If they have any fault, it is that they are often over-elaborate, the work of a man who evidently loves diplomacy for its own sake and glory in the fine turn of a phrase. In this respect they are comparable to those of Canning, who modelled himself upon Chateaubriand; the Foreign Office, as the House of Commons used to call it, on Castlereagh. Metternich almost invariably begins his despachets and his reports with a broad discussion of the principles involved in the case in point, and argues from these down to the facts. In this again he is in sharp contrast with Castlereagh, who, with characteristic British practical sense, boldly sweeps the principles aside and prefers to argue upward from the facts. Yet Metternich's phrase-making was often the result of astute calculation. His diplomatic genius was never so well displayed as in disguising perilous issues in phrases that soothed even when they did not deceive. In a despatch, if the occasion demanded it, he was master of the art of appearing to say much when in fact he said nothing. When he wished to make his meaning plain, no one could do so more clearly; when he wished to be reticent, no reticence could have been more pleasingly eloquent.

In private life Metternich was a kind, if not always faithful, husband and a good father, devoted to his children, of whom he had the misfortune to lose several before his death. He was three times married. His second wife, Baronesse Antonie von Leykam, Countess von Bellstein, died in 1829; his third wife, Marie, Countess Jozef Ferraris, died on the 3rd of March 1854, of Castlereagh. Metternich almost invariably begins his despachets and his reports with a broad discussion of the principles involved in the case in point, and argues from these down to the facts. In this again he is in sharp contrast with Castlereagh, who, with characteristic British practical sense, boldly sweeps the principles aside and prefers to argue upward from the facts. Yet Metternich's phrase-making was often the result of astute calculation. His diplomatic genius was never so well displayed as in disguising perilous issues in phrases that soothed even when they did not deceive. In a despatch, if the occasion demanded it, he was master of the art of appearing to say much when in fact he said nothing. When he wished to make his meaning plain, no one could do so more clearly; when he wished to be reticent, no reticence could have been more pleasingly eloquent.

BIBLIOGRAPHY.—A vast mass of unpublished material for the life of Metternich exists, both in public and private archives; to some of those in the F.O. Records references are given in the bibliog. to chap. I. of vol. XII. of the Cambridge Mod. Hist. Of published documents, the most important are in the collections Aus Metternichs nachgelassenen Papieren (6 vols., 1859-1884), edited by his son, Prince Richard Metternich. There is a complete French translation issued contemporaneously, and an English version, of which the first volumes, devoted to the most important are in the collection Aus Metternichs nachgelassenen Papieren (6 vols., 1859-1884). These Memoirs, especially the autobiographical parts, must be read with considerable reserve; even the official letters and documents, which are their most valuable contents, have been to a certain extent "edited. See also Count Anton Prokesh-Osten (the younger) Aus dem Nachlass von Prokesh-Osten (2 vols., Vienna, 1881); the writings and correspondence of Friederike von Goe (5 vols., 1876-1884), which provide fresh and illuminating material, especially into the life of the Empress Theophania von Bayern, as well as into the lives of the chief participants in the Napoleonic Wars; Wilhelm Oncken, Österreich und Preussen im Befreiungskriege (1875-1879); A. Beer, Zehn Jahre österreichischer Politik, 1801-1810 (1877); Die Finanzen Österreichs (1883); Die österreichische Politik

METZ, a town, first-class fortress and episcopal see of Germany, in the imperial province of Alsace-Lorraine, capital of (German) Lorraine, on the Moselle, 99 m. N.W. of Strassburg by rail, and at the radiation of lines to Luxembourg, Coblenz and Nancy, on the French frontier (103 m. W.). Pop. (1905), 60,936. The general appearance of the town is quaint and irregular, but there are several handsom e modern streets. The Moselle, which is here joined by the Seille, flows through it in several arms, and is crossed by fourteen bridges. In the south-west corner of the town is the esplanade, with an equestrian statue of the emperor William I., and monuments to Prince Frederick Charles and Marshal Ney, commanding a fine view of the "pays mersin," a fertile plain lying to the south. Of the ten city gates the most interesting are the Porte d'Allemagne, or Deutsche Tor, on the east, a castellated structure erected in 1445 and still bearing traces of the siege by Charles V.; the Porte de Serpenoise, or Römer Tor, on the south, and the Porte Francaise, or Französische Tor, on the west. Among its ecclesiastical edifices (nine Roman Catholic and four Protestant churches) the most noteworthy is the Roman Catholic cathedral, with huge pointed windows, slender columns and numerous flying buttresses, which, begun in the 13th century and consecrated in 1546, belongs to the period of the decadence of the Gothic style. The Gothic churches of St Vincent and St Eucharius, and the handsome Protestant garrison church, completed in 1881, also deserve mention. Among secular buildings the most important are the town-hall, the palace of justice, the theatre, the governor's house, and the various buildings for military purposes. The public library contains 40,000 volumes, including an extensive collection of works relating to the history of Lorraine. In the same building is the museum, which contains a picture gallery, a numismatic cabinet, and a collection of specimens of natural history. Metz also possesses several learned societies, charitable institutions and schools, and a military academy. The cemetery of Chambière contains the graves of 7200 French soldiers who died here in 1870. The chief industries are tanning and the manufacture of leather and other leather goods, and artificial flowers. There is a trade in wine, beer, wood and minerals.

As a fortress, Metz has always been of the highest importance, and throughout history down to 1870 it had never succumbed to an enemy, thus earning for itself the name of La pucelle. It now ranks with Strassburg as one of the two great bulwarks of the west frontier of Germany. The original town walls were replaced by ramparts in 1530, and the citadel was built a few years later. By 1674 the works had been reconstructed by Vauban. Under Napoleon III. the fortress was strengthened by a circle of detached forts, which, although surmounted and completely captured by the Germans in 1870, treated the fortress as the principal pivot of offensive operations against France. The plans in FORTIFICATION and SHEEPCRAFT (fig. 43) show Metz as it was about 1900; in the years following a new outer chain of defences was constructed, which extends as far as Thionville on the north side and has its centre in front of Metz on the Gravelotte battleground. The old enceinte (which includes Cormontaigne's forts—Moselle and Belleville) is doomed to demolition, and has in part been already removed. The garrison, chiefly composed of the XVI. Army Corps, numbers about 25,000. (See La pucelle.)

History.—Metz, the Roman Divodurum, was the chief town of the Mediomatrici, and was also called by the Romans Österreic...
METZ

Mediomatrica, a name from which the present form has been derived by contraction. Caesar describes it as one of the oldest and most important towns in Gaul. The Romans, recognizing its strategical importance, fortified it, and supplied it with water by an imposing aqueduct, the remains of which still exist. Under the Roman emperors Metz was connected by military roads with Toul, Langres, Lyons, Strasbourg, Verdun, Reims and Trier. Christianity was introduced in the 3rd century of our era. In the middle of the 5th century the town was plundered by the Huns under Attila; subsequently it came into possession of the Franks, and was made the capital of Austrasia.

On the partition of the Carolingian realms in 843 Metz fell to the share of the emperor Lothair I. as the capital of Lorraine. Its bishopric, whose creation reaches back to the 4th century, now began to be very powerful. Metz acquired the privileges of a free imperial town in the 13th century, and soon attained great commercial prosperity. Having adopted the reformed doctrines in 1552 and 1553, it fell into the hands of the French through treachery, and was heretically and successfully defended against Charles V. by Francis duke of Guise. It now sank to the level of a French provincial town, and its population dwindled from 56,000 to about 22,000. At the peace of Westphalia in 1648 Metz, with Toul and Verdun, was formally ceded to France, in whose possession it remained for upwards of two centuries. The battles of August 1870, and the investment and capture of the army of Metz which followed, are described below. By the peace of Frankfurt on the 10th of May 1871 Metz was again united to the German Empire.

See Westphal, Geschichte der Stadt Metz (1875–1877); Georg Lang, Metz und seine Umgliederungen (1883), the Statistik-geographisches Handbuch für Lothringen; Albers, Geschichte der Stadt Metz (Metz, 1902); G. A. Proost, Études sur l'histoire de Metz (1897); and Tauber, Die Schlachfelder von Metz (Berlin, 1902). (See also FRANCO-GERMAN WAR: Bibliography.)

Battles around Metz, in the Franco-German War, 1870

1. Colombey-Borny (August 14).—The French army under Marshal Bazaine was in and about Metz. The German I. and II. armies, on the march from the Saar, were heading for the Moselle between Metz and Pont-à-Mousson, and on the morning of the 14th of August the German I. Army (I., VII. and VIII. Corps, under General v. Steinmetz) lay on and east of the French, with outposts well to the front, watching the French camps east of Metz, which were now some 8 m. to the front. Steinmetz had received from headquarters overnight instructions that on the 14th of August the I. Army would maintain the positions occupied during the 13th, and merely pass these orders on to his corps commanders. In Metz, meanwhile, Bazaine had decided to retreat, and during the morning orders to that effect reached his corps commanders, who commenced preparations for their execution. The 2nd Corps (Bazaine), 4th (Canrobert) began to retire about midday, the 3rd (Leboeuf), 4th (Ladmirault) and Imperial Guard (Bourbaki) were to follow.

These preparations being observed, the German outposts got under arms. General von der Goltz, in command of the VII. Corps (7 battalions, 4 squadrons, 2 batteries) hearing from a passing officer that the I. Corps on his right was preparing to attack, and noting personally signs of retreat in the enemy’s lines, determined at 3 p.m. to advance his whole command to the ridge between Colombey and Borny (which was still occupied by French outposts), in order to clear up the situation. The ridge was captured with little resistance, but the sound of the firing once set all the neighbouring troops in motion, and fortunately so, for the French had immediately retaliated on von der Goltz’s audacious attack. Between 4 and 6 p.m. there was continuous heavy fighting on the front from Borny to Méry, as both sides brought fresh troops into the field. The convex slopes falling from the Prussian position towards Metz gave plenty of cover to the French, and the setting sun shone full in the faces of the Prussians. Thus the Prussian infantry encountered unusually obstinate resistance, and the French troops engaged rapidly slipped from all superior control. The above front was held by the French 3rd Corps. Shortly before 6.30 the 4th Corps (Ladmirault) suddenly began to deploy on the high ground to the north-west beyond Méry, thus threatening the right flank of the Prussian I. Corps (General v. Manteuffel). To meet this danger Manteuffel was compelled to direct his corps artillery and reserves, which were now rapidly coming up, away from the hard-pressed centre towards the oncoming infantry masses of Ladmirault. These, with the sun now almost at their backs, were shooting better than usual, and Manteuffel was compelled to call on the VIII. Corps for assistance, which its commander, under positive orders from Steinmetz, refused to give. Meanwhile Steinmetz had been sending peremptory orders to the battlefield to stop the battle, but neither of the corps commanders was able to enforce them. Fortunately for the Prussians, Bazaine had issued similar orders to his subordinates, who, having their men better in hand, were able to obey; and as night began to close in the French broke off the action and retired under the guns of the Metz forts, convinced that at last they had “broken the spell” of German success.

Finding that in spite of his orders, the firing at the front continued increasing in intensity, Steinmetz at length rode to the front himself. Meeting Manteuffel near the Brasserie de Noiselle, he overconvinced him with reproaches, and at the crisis of this scene the bands struck up “Heil dir im Siegesschrank!” In this action the Germans brought 30,500 rifles and 150 guns on to the battlefield only out of more than 100,000 with 300 guns which could have been engaged before darkness. Bazaine actually deployed 50,700 rifles and 266 guns to oppose them. He might, however, had he been so minded, have struck with his whole army at least three times this force, and, judging from the events actually took place, we can have little doubt that to the result of such a blow. The losses on either side were in killed and wounded—French about 3600, Germans about 4800. The chain of causation in this action is particularly worthy of attention: A young reserve officer, seeing some troops of the I. Corps standing to arms, reported to von der Goltz that the corps was standing to arms and about to attack. Von der Goltz thereupon decided to go forward and discover what was actually going on, and this action unchained the whole battle power of all the troops within call. When, on the following morning, Steinmetz reported von der Goltz and the commander of the I. Corps for disobedience, the king thanked Manteuffel warmly for the part he had played, and then turned to the young brigadier who had disobeyed orders and congratulated him on having twice distinguished himself in the first fortnight of the war.

2. The Battle of Vionville—Mars-la-Tour (August 16).—On the following day (15th) the II. German Army approached the Moselle above and below Pont-à-Mousson, with a view to overtaking and heading off Bazaine in his presumed retreat to the Meuse (see FRANCO-GERMAN WAR). So far, however, from being ahead of the Germans on the road to Verdun, the French were actually, late in the afternoon of the 15th of August, bivouacked on the plateau of Rezonville, and there their outposts were placed, not where they could see the surrounding country, but at the regulation distances of 600 to 1000 paces from the bivouacs. Friendly inhabitants kept Bazaine well informed as to the magnitude of the danger threatening him from the south, and a special telegram from Paris, the true origin of which has never been traced, led him to believe that the I. German Army was crossing the Moselle near Thionville and about to descend on him. From the north, in the meantime, the enemy had been exercising the most prejudicial influence on the course of the battle had not Ladmirault (4th Corps), nearer to the seat of the imaginary danger, taken upon himself to disregard the warning transmitted to him by headquarters. At daybreak on the 16th, no Prussians being reported in sight by the outposts, the troops began nonchalantly to prepare for the resumption of the march.

On the Prussian side, von Alvensleben’s Corps (III.) shortly after daybreak was moving north-westward from the Moselle in two columns, on the right the 5th division, via Gorze and Flévy to Vionville, on the left the 6th division with corps artillery by Arnaville on Mars-la-Tour, von Alvensleben himself riding
a little in advance between the two. The 6th cavalry division was ordered to precede the right column and scout towards Rezonville. No one was aware of the dangerous proximity of the French army.

About 9 a.m. the 5th cavalry division, reinforced by two horse artillery batteries (flank guard of the X. Corps from Thioncourt), and accompanied by von Caprivi (chief of staff, X. Corps, and afterwards chancellor of the German Empire), were trotting up the western slopes of the ridge which runs between Tronville and Vionville. Reaching its summit they from Gorze towards Vionville, whence he could overlook the whole country to the north and west, had met von Rheinbaben (commanding the 5th cavalry division) and had seen the surprise of the French camps. The sound of the heavy firing coming from the eastward convinced him of what had been gradually dawning on him—that with barely 30,000 men he was in the presence of the whole French army, whose attitude at this moment sufficiently indicated their determination to fight.

In a few moments his decision was taken. Calling on the X. Corps, away to the south-westward, for support, he determined

Scale, 1:60,000

English, Miles

suddenly found themselves in face of at least 40,000 French troops, which were not under arms, but busied with miscellaneous camp duties. The temptation proved too great for the artillery, who promptly fired into the midst of the cavalry camp (Forton's division) which lay nearest to them. The momentary result was a wild panic, especially among the horses; but this panic gave the alarm to the infantry all along the road, and these (Frossard's 2nd Corps) at once stood to arms and moved forward, deployed for attack—one division to the west, another division, from Rezonville, to the south. The latter almost at once encountered the heads of the 6th cavalry division, at that moment just clearing the defile leading up to the Rezonville plateau from Gorze. The Prussian cavalry promptly bore away to cover to the westward, and reported what they had seen to superior authority, but not to the advance guard of the 5th infantry division, which, emerging in its turn from the defile, ran right against the deployed French infantry moving to meet them. So sudden was the collision that the Prussian advanced guard battery had to fire case to clear its own front. Meanwhile von Alvensleben himself, riding on the field track to screen his own weakness by a vigorous attack. By universal consent this is approved as the boldest resolution arrived at by an independent commander throughout the war. Orders were forthwith despatched to the 6th infantry division, at that moment between Puxieux and Tronville, to wheel in to their right and attack, and, their movement being still hidden from the enemy, these troops were formally drawn up for action and sent forward as a whole. The French meanwhile had occupied Vionville and Flavigny, and other troops were moving down the slopes from Rezonville to their support, but the united onset of this whole German division overrode all resistance, and the French began to retire eastward, suffering terribly from the shell fire of the Prussian batteries.

Marshal Bazaine had meanwhile arrived on the scene, and ordering forward fresh troops to relieve (not to reinforce) those already engaged, he rode forward with a horse artillery battery to watch the operations. The retreating French troops belonged to Frossard's command, and as they were in considerable confusion Frossard called on du Preuß's brigade of the imperial guard cavalry to charge. He gave no objective, and when the
brigadier pointed out that the enemy was still beyond the striking radius of his horses, Frossard reiterated the order, which was obeyed to the letter.

The result was disastrous. The Prussians, having seen the cavalry whilst yet at a distance, ceased firing, formed their skirmishers into groups, and the closed supports standing in deployed lines, two deep, shattered the cavalry with volleys and file-firing, as with blown and exhausted horses they endeavoured to close with their adversaries. When in addition two hussar regiments struck them in flank they were driven back in wild disorder upon Rezonville. In the dust and confusion of the charge a group of the hussars approached Bazaine and his horse artillery battery, and almost carried off the marshal.

Alvensleben, mistaking the withdrawal of the French for the beginning of a retreat, had meanwhile sent orders to the 6th cavalry division to charge in pursuit towards Rezonville; but before it could reach the field the French relieving troops had forced their way through the stragglers and showed such a bold front to the Prussian horsemen that an attack held no promise of success, more especially since they had lost their intervals in their advance and had no room for a proper deployment. To steady the young soldiers, the cavalry commander (Carl von Schmidt) halted his men, made them correct their intervals and dressing as in peace, though under a heavy fire from the French infantry, and then withdrew them behind the cover of the nearest hill at a walk.

The threat of the charge had, however, induced caution on the French side, and for about two hours there was a lull in the fighting, which the Prussians utilized on their right in bringing up reinforcements through the Bois des Ongons. On their left, however, no fresh troops were as yet available, and when being informed, about 2.30 p.m., that French cavalry seemed to be about to charge the exhausted 6th division, Alvensleben ordered Bredow’s cavalry brigade to charge, and if necessary to sacrifice itself, to save the infantry. Bredow’s command (six squadrons of the 16th Ulan and 7th Cuirassiers) was at that moment drawn up under cover about half a mile west of Vionville, and from its position could see nothing of the events in progress on the battlefield. Notified by the form in which the order was conveyed to him, Bredow drew his sword and ordered his trumpeter to sound the “trot,” the brigade moving off in line of squadron columns at close interval in the direction in which they happened at the moment to be facing. Near Vionville they took ground to their left, opening to full intervals as they did so, and then ascended the gentle incline which still hid them from their enemy.

Arrived at the summit, Bredow sounded “line to the front,” but at that moment a storm of French bullets swept down on them, and the men, no longer to be restrained, dashed forward, before the line could be completed, almost due east against long lines of infantry and artillery which they now saw for the first time about 1200 yards in front of them.

This distance was covered at the fullest extended speed of the horses, and reaching the infantry they swept over them “like hounds over a fence”—in the words of an eyewitness. So sudden had been their onset that very few were hit until the infantry had been passed; then the latter, recovering from the shock, turned and fired into the cavalry from behind, whilst a whole fresh division of French horsemen charged them in flank. After a desperate mêlée of some minutes, the rally was sounded, and the survivors of the charge, breaking their way, passed through the French infantry, eventually reached the shelter of their own lines, having lost rather more than half their numbers, but having saved the situation momentarily for their own army. Again there was a lull in the operations.

Meanwhile, unknown to Alvensleben, a fresh storm was brewing on his left rear.

Ladmirault, commanding the French 41st Corps, had seen, during the afternoon of the 15th, the terrible crowd and confusion prevailing in the débris leading to Gravelotte, and resolved to disobey his orders and to move his brigades by the road from Vionville to St Privat, disregarding altogether the alleged danger from the Prussians supposed to be advancing from Thionville. Thus, about noon on the 16th he reached the high ground between St Privat and Amanvillers, and, still without instructions he determined to direct his corps on Bruville and Doncourt, whence he could judge from the drift of the smoke-clouds whether he could fall on the Prussian left.

Much time was lost owing to the heat of the day and the fatigue of the troops, but shortly after 3 p.m. he reached a position north of the 15th, the terrible crowd and confusion prevailing in the débris leading to Gravelotte, and resolved to disobey his orders and to move his brigades by the road from Vionville to St Privat, disregarding altogether the alleged danger from the Prussians supposed to be advancing from Thionville. Thus, about noon on the 16th he reached the high ground between St Privat and Amanvillers, and, still without instructions he determined to direct his corps on Bruville and Doncourt, whence he could judge from the drift of the smoke-clouds whether he could fall on the Prussian left.

Ladmirault, commanding the French 41st Corps, had seen, during the afternoon of the 15th, the terrible crowd and confusion prevailing in the débris leading to Gravelotte, and resolved to disobey his orders and to move his brigades by the road from Vionville to St Privat, disregarding altogether the alleged danger from the Prussians supposed to be advancing from Thionville. Thus, about noon on the 16th he reached the high ground between St Privat and Amanvillers, and, still without instructions he determined to direct his corps on Bruville and Doncourt, whence he could judge from the drift of the smoke-clouds whether he could fall on the Prussian left.

Maj-Gen. Bredow, with the 6th cavalry division, was at this time on the right of the French army, engaged in operations on the right flank, which were not at all successful. His horse was shot from under him, but he endeavoured to escape by the road leading to Vionville, but being pursued, endeavoured to reach the road between Amanvillers and Thionville, but was captured by the French cavalry and his staff.

This division was brought about by the arrival of the corps artillery of the X. Corps and of the 40th brigade, which latter had been at once ordered into the Tronville copse to check portions of Tixier’s division of the French 3rd Corps, which under cover of these copse had gradually worked round the Prussian flank. Seeing then that the troops before him could hold their own, Ladmirault continued his preparations for his counter-stroke, and Cissey’s division had begun to move into its prescribed alignment, facing towards Vionville, when the sudden appearance of a closed mass of Prussian troops detachment itself from the low dust-cloud of a slow-moving infantry column, and forming to the south of Mars-la-Tour, again arrested his attention. Unanimously he and his staff agreed that this fresh enemy could only be the advanced guard of a large Prussian corps. Possibly, it was suggested, of the crown prince’s army, from Alsace and Nancy, and a fresh delay arose whilst the situation was investigated. Actually this body consisted only of the 38th brigade (von Wedell), forming part of the X. Corps. It had no knowledge of the state of affairs on the battlefield, or in the direction of Bruville, though Prussian cavalry had been observing the approach of Ladmirault’s corps for some hours. It was now ordered to deploy and to co-operate with the 40th brigade in an attack on the Tronville copse. This meanwhile had been delivered, and had more or less failed.

The deployment completed, about 4 p.m. the 38th brigade began its advance on the north-west corner of the Tronville copse, this direction taking them diagonally across the front
The Prince of Prussia endeavoured to change front half-left whilst still on the move. Without pausing to fire, the men raced onward, but the French striking their outer wing rolled up the whole line in succession, the actual collision occurring in and near the Bruvill ne, a deep-cut natural trench which, starting from the Trouville copses, here intersects the plateau from west to east. Against the weight of French numbers, nearly three to one, the Prussians were unable to stand, and presently they broke and drifted backwards, completely routed. Then the 1st Guard Dragoons (since known as Queen Victoria's regiment), after a brilliant manœuvre under heavy fire, to get into the best position for delivering a charge, rode down the whole French line of pursuers from left to right, and by their heroic self-sacrifice relieved the remnants of the infantry from further pursuit.

This was the scene which for the moment held the attention of Prince Frederick Charles when at length he reached the battlefield from Pont-à-Mousson. All along the rest of the line the Prussians were still holding their own, and on the extreme right fresh troops from the IX. Corps were streaming up through the woods against the French left wing. But on the left there was a most serious disaster—two battalions of the Guard being cut off by the cavalry, which was there, sending, therefore, hasty orders to the 5th and 6th cavalry divisions to concentrate to the west of Mars-la-Tour, the prince ordered them from there to sweep round on the right rear of the French army. The same idea had, however, occurred to Ladmiraull, and he had called on the two nearest French cavalry divisions to put it into execution, and as the Prussians began to reach the plateau west of Mars-la-Tour and the Yron brook from the south, the French were deploying across it some two thousand yards to the north.

Thus the one great cavalry duel of the war—between upwards of two thousand horsemen a side. But it was delivered by both sides in a series of regimental charges, and in result was singularly indecisive. For about half an hour the French were superior to the enemy's cavalry and eventually charged to within a few hundred yards of the French army. The engagement gradually ceased.

It was now about 7 p.m. and night was coming on. Seeing the French infantry advancing northward, and noting the lethargy which seemed to have settled over the whole French line, Prince Frederick Charles decided to assert his own independent will to conquer by a final assault along his whole front. Guns, cavalry, infantry, everything that could still stand were to take part in it. Weary as they all were, his indomitable will push fresh life into the whole army. With drums beating and colours flying, every unit within call went forward for the final effort. It was almost dark when the French began to retreat towards Rezonville and the woods to the northward, and the troops soon lost sight of the smoke and became involved in the direct confusion; the fire again blazed out for a few moments, only to die away as utter exhaustion at length put an end to the Prussian advance. Then the wearied troops, for the most part, lay down and slept in the positions they had reached.

Thus closed the hardest fought battle of the Franco-German War. From 3 a.m. to 3 p.m. only 23,700 rifles, 8,000 sabres and 126 guns had been brought into action by the Germans against 59,100 rifles, 6,700 sabres, and 350 guns on the French side, and even at the close of the day the former had only deployed 47,100 rifles, 8,300 sabres and 222 guns against 83,900 rifles, 8,000 sabres and 432 guns including 24 mitrailleuses. The chief characteristic of the day's fighting was the terrible effectiveness of the Prussian artillery, which was handled in masses and not, as on the French side, by battalions. The manouevring powers of the latter attracted the admiration of the Germans, but arriving singly on the field they were generally reduced to silence in a few minutes. Deprived of their support, not all the gallantry of the French infantry could avail anything. Again and again, particularly on their left wing, they charged the German infantry before them, but the moment the retreat of the latter downhill began the pursuing French to the Prussian guns, a tornado of shells shattered their order and compelled them to retreat. Though the cavalry were freely engaged, the training of both was so far beneath the standard of the present day that the most that can be credited to them in respect of results is that they from time to time averted imminent disaster, but failed altogether to achieve such a decision as was well within their potential capacities.

3. Gravelotte—St Privat (August 18).—The position on which the French army fell back from the field of Vionville is formed by a ridge some six miles long running from Rozieries almost due north to Roncourt, a little village overhanging the steep and wooded banks of the Orne, and connected with the general plateau between the Meuse and Moselle by a gentle saddle running from about Amanvilliers nearly due west through the Bois de la Cuasse towards Doncourt. North of this saddle the slopes show a slight concavity, but are passable by troops of all arms in close order. To the south the rivulet of the Mance soon forms a formidable obstacle as its bed cuts its way through the sandstone. Scrub and woods with dense undergrowth line both sides of the road. The French had established a strong, except by the great caissons from Metz to Verdun, access to the French side becomes impossible to troops in ordered bodies.

It does not appear that the position had been systematically examined, or apportioned to the several corps in accordance with any predetermined plan. The army merely swung backwards, pivoting on its left wing, the corps preserving their relative order as it had been at the 10th, with the exception that the Imperial Guard was withdrawn to the spur on which Fort Plappeville stands, and the 6th Corps (Marshal Canrobert) formed the line of march of the 3rd and 4th Corps in order to gain St Privat la Montagne. No lines of road corresponding to the several units, consequently the confusion became so great that though the distance to be traversed in no case exceeded six miles, only the right wing and centre reached their destinations as night was falling. Many of them had so little idea of the general situation that they actually placed outposts to the north and east, whilst the whole of the enemy's army lay to the south and west. No attempt was made to entrench the position systematically, but on the left the 3rd and 3rd Corps made some shallow shelter trenches and gun-pits, while the 4th Corps in the centre began to improve available cover about an hour before the battle began, and the 6th corps on the right, not yet having received any entrenching tools, could do no more than improvise a few loopholes in the walls of the villages of St Privat and Roncourt with such tools as the sappers could obtain from the inhabitants.

Fortunately for the French the Germans were too exhausted by the battle of the 10th to attempt to interfere with these movements. At daylight on the morning of the 18th the royal headquarters (which now for the first time arrived at the front) still had no certain knowledge as to whether the French main army was in retreat—covered by the force which they could see on the high ground north of the Metz road—or whether they had taken up a position in order to fight.

Hence the orders issued overnight on the presumption that the main force of the French was retreating to the north and west were allowed to stand, and the whole II. Army (Prince Frederick Charles) moved off in echelon from left to right, the I. Army under Steinmetz, consisting for the day of the I., II. and VII. Corps, being left in observation of the troops visible on their front and of the garrison of Metz itself. The I. Corps was kept back beyond the Moselle on the east side of Metz, the II. was not due to arrive at Rezonville before 4 p.m., hence the VII. only was immediately available if the enemy counter-attacked. But Steinmetz had not ordered, nor had von Zastrow, the corps commander, undertaken, any preparations to meet an emergency.

About 10 a.m. the army had reached the following positions:
VIII. Corps, Rezonville; XI. near St Marcel; Guard approaching Doncourt; XII. towards Jarny; the III. and X., which had been so heavily engaged on the 16th, still in their bivouacs preparing to move. The cavalry of the Saxons had established the fact that the French had not retreated northward, but though scouts from the Guard had already seen the enemy on the heights of St Privat, this information had not yet reached headquarters, nor had it been transmitted to the IX. Corps, which it most closely concerned.

Shortly after 10 a.m. Moltke, still under the impression that the French right extended no farther than La Folic (2 m. north of the Metz road), determined to attack with the IX. and VIII. Corps whilst the Guard executed a turning movement via Habonville against the French right. The IX. Corps was to engage, but not to push its attack home until the Guard could co-operate. The XII. Corps was left to its own devices, but fortunately the crown prince of Saxony, who commanded it, had ridden forward and, seeing the French in force towards Roncourt, had issued orders which in the event proved decisive.

In pursuance of his instructions von Manstein, commanding the IX. Corps, set his two divisions in motion towards La Folic and the Bois de la Casse, and advanced to reconnoit the French position. From the eastern edge of the above-named copse he suddenly descried the camp of a whole French Corps (the 4th), evidently ignorant of their danger, on the slopes trending westward from Amanvillers. Unmindful of the experience of the 16th, he decided to execute an artillery surprise on a grand scale, and sent orders to his corps artillery to come into action on the long spur overlooking the French camps from the westward. At noon, just as the French infantry were falling in for midday roll-call, sufficient guns were in position, and suddenly opened fire. But the effect was disappointing. The French infantry ran to their arms, piled along the front of their positions, and moved forward to attack, covering their advance by a hail of bullets. Simultaneously the French artillery also took up the challenge, and from the heights near St Privat the 6th Corps, whose presence had been unsuspected by the Prussians, joined in the fight.

In a few minutes the batteries on the extreme Prussian left were completely overwhelmed, and suddenly dense lines of French skirmishers emerged from a fold in the ground upon their flank and front, and the gunners were compelled to resort to case-shot, so imminent was their danger. But at this critical moment the leading companies of the Hessian infantry arrived, re-established the equilibrium (though not before four Prussian battalions had temporarily overrun by the enemy), and a most obstinate fight ensued.

Prince Frederick Charles now rode forward to a point north-east of Vernéville, whence the southern boundary of St Privat could be seen. But the northern side of the village and the country towards Roncourt was hidden from his view by the high poplars bordering the Metz-Briey road. Seeing the Hessians hard pressed, he now brought forward the 2nd division of the Guard to their assistance, sending in the 3rd brigade immediately, and holding the 4th brigade in reserve. The 1st division, warned by their own scouts that French troops were in St Marie, deployed to attack this village, and were assisted in their endeavour by a brigade of Saxons detached by the crown prince of Saxony, who from his position could see behind the poplar screen that limited the view of the commander-in-chief. Hence he was already aware that the French position extended to Roncourt at least, and had despatched a whole division down the valley of the Orne to outflank them. No news of this movement, however, appears to have reached Prince Frederick Charles.

In St Marie were only an outpost of the 6th corps, and seeing themselves outnumbered, they withdrew about 9.30, the Prussians rushing the village immediately afterwards. Considerable confusion arose from the convergence of these three brigades upon one village, and more than an hour passed before the troops could be disentangled and massed for further operations. The leaders of the two Guard brigades, still ignorant of the extent of the French position, rallied their men on the main bodies of their commands (which had not been engaged) and then lay down facing exactly as they had done when brought forward to the attack. Thus the 1st brigade lay, facing about east-south-east, south of the chaussee and some five hundred yards west of the village. The 2nd brigade lay south-west of the village about three hundred yards away from them, facing nearly north-east.

The Saxons were on the left rear of the 1st brigade, but took longer to recover themselves than the Guards. With the Hessians and the IX. Corps the action still dragged; the 3rd brigade of the Guards had become involved in the fight, and notwithstanding the arrival of the corps artillery of the III. Corps in the centre the situation was still critical. From the south also came the thunder of guns and no encouraging news from that quarter had as yet reached the prince's headquarters.

About 4.30 p.m. the prince therefore had to consider how long it would take to obtain a decision. To push one more time would the morrow seemed undesirable: to achieve it before nightfall was only possible at the cost of immediate effort.

He therefore decided to assault St Privat, with all the Guards available, and called up the III. X. and Saxons to assist them. The 4th brigade of the Guards now received their orders to attack Jérusalem (a hamlet a little south of St Privat), and the 1st division was ordered to assault St Privat itself.

Von Pape, commanding the latter division, pointed out that no artillery force adequate to prepare the way for him on the 5th instant, and that the arrangement of the 4th brigade was such as to allow of the 4th corps in its extension for attack to overlap the front assigned to the 2nd, hence a further (half-left) wheel, still in mass, had to be undertaken before room for deployment could be obtained. Almost as the commands were given, the French suddenly opened an overwhelming long-range fire and their bullets swept like hail through the crowded mass of the German troops. Nevertheless the wheel was effected, the fresh direction taken, the troops extended for attack, and then the whole brigade dashed towards the houses assigned as the objective. Meanwhile the 1st brigade had moved round the north of the village and carried out its extension, without serious hindrance. But emerging from the hollow running north from St Marie, they came under a heavy fire not only from St Privat but also from Roncourt, which latter village they now saw for the first time. Instinctively a portion of their line worked to the left to face this new menace, and the front thus became dangerously extended. They were, however, now abreast of the 2nd brigade, and the whole line raced forward to reach the effective range of their very infernial weapons, which were about equal at 200 yds. To the French rifle at 600 yds, the 2nd brigade, particularly in officers, had been too heavy, and the rush died out whilst still 500 yds from the two villages.

It was now about 6 p.m. and a long pause ensued, while the 230 guns, which by degrees had unlimbered behind them, brought St Privat and Roncourt under fire. About 7 p.m. the Saxon turning-movement took effect; their infantry from the Orne valley attacked Roncourt from the north, and about 7-15 the village was carried.

Neither Prince Frederick Charles nor the troops in the fighting-line could see what had taken place; but the former seeing other Saxons moving towards Montois and the masses of the III. and X. Corps approaching, whilst the rain of shells into St Privat exceeded anything hitherto seen on any battlefield, decided to call on the whole of his force to attack. He was in
the act of issuing his orders when a psychological wave swept through the fighting-line, and the men rose and rushed the village at the point of the bayonet. It was now about eight o'clock, and the light was rapidly failing.

The French artillery had already preceded the coming blow, and the heavy guns of the "right back," to cover the flank of the rest of the army, and the Prussian and Saxon artillery trotting forward conformed to this new front, their shells sweeping the ground for 2000 yds. to the south of Amanvillers. The confusion in and around St Privat, where troops from four several corps were all intermingled, became so extreme that no further infantry-advance could be attempted; so under cover of the fierce artillery duel the remnants of the unfortunate 6th corps drifted away towards Metz down the many ravines leading into the river valley. The "annihilation of the Guard at St Privat has become historic. Yet, heavy as were the losses of the 1st Guard division they were not excessive compared to those previously endured. In round numbers one-third of their effective had fallen—most of them in the first great rush forward at 5.30 p.m.; but actually they had been more or less under fire since about 2 p.m., and many were hit by French shells plunging into the turmoil about St Privat from 8 to 10 p.m. But the legend cannot be justified when the facts are compared with the slaughter of the Seven Years' War, of Napoleon's battles, the Crimea, and the American Civil War.

It is now time to return to the southern theatre of the battlefield, where an entirely independent engagement had been raging all the afternoon. Von Goeben with the VIII. Corps was standing massed about Rezonville when von Steinmetz's guns opposite Amanvillers suddenly made themselves heard. Wheeling his corps to face the French to the eastward he immediately sent forward his artillery and prepared to support his comrade. Von Zastrow with the VII. Corps followed his example. Both corps being as their primary object to protect the left of the Hubertus and Point du Jour, standing just above the defile made by the Verdun-Metz road where it climbs out of the Mance ravine towards the French position. About 3.30 to p.m. St Hubert was carried by a confused mass of some 40 companies, and von Steinmetz, believing the main French position to have been pierced, ordered the 4th cavalry division to cross the ravine by the chaussée and pursue. Simultaneously von Zastrow, under the same impression, had ordered his corps artillery to advance by the same road, and von Goeben, thinking his troops in front required support, had sent forward an infantry brigade and a portion of the heavy cavalry.

Presently all these columns converged upon the defile and a hopeless entanglement ensued. Three batteries succeeded in struggling through the mass, and, in coming into action, their left resting on St Hubert. But the remainder of the troops had to be withdrawn, and confusion breaking out in their rear, exposed to all the random bullets and shells of the French, a panic ensued, thousands of men breaking away and flying in wildest confusion through Gravelotte towards the west. Hardly had they melted away when the French made a most brilliant counter-attack from their main positions between the Hubertus and Point du Jour, massed on the extreme left of the corps. This was stopped almost entirely by the Prussian artillery fire; but the news of its coming spread through the stragglers in the ravine south of the great road, and a wave of panic again swept through the mass, many thousands bolting right upon the front of their own batteries, thus masking their fire at the most critical moment, and something like a crisis in the battle arose. Fortunately the II. Corps was just rapidly approaching (about 6 p.m.), and the king, against Moltke's advice, now ordered von Steinmetz (to whom the II. Corps had been allotted for the day) to attack again with all his forces. Meanwhile a third panic broke out which delayed the preliminary movements and it was now growing dark in the ravine. At length the II. Corps, together with all of the VII. that could be collected, moved down into the valley. Just as the leading German troops were approaching

St Hubert the French again began to fire, their bullets plunging down among the fresh arrivals, who knowing nothing of what had taken place about St Hubert (where the remnant of their own infantry were still offering a desperate resistance) opened fire into the backs of their own men, and a Fourth panic began as the march to the stragglers crowding the Mance ravine. Fortunately, by the superb gallantry of some of the company officers and men, the new arrivals were induced to recognize their mistake, and by degrees about 10 p.m. the whole of the II. Corps succeeded in reaching the plateau between St Hubert and Point du Jour, where the debris of the VII. and VIII. Corps had gathered. But in the darkness and confusion no forward movement against the French (only 400 yds. to their front) could be initiated, therefore the whole mass passed the night where they stood until daylight disclosed that the French had retreated.

Meanwhile the king, Moltke, and Bismarck, had ridden back behind Gravelotte where they passed two hours of intense anxiety. From the flash of the rifles, it was clear that the French main position was still intact, and as every body of troops within thirty-six hours' call had been engaged there seemed little prospect of renewing the struggle next morning. No news too had come in from Prince Frederick Charles. Ultimately about midnight the welcome tidings of the capture of St Privat arrived, and all anxiety was at an end.

CA. The Investment of Metz (Aug. 19-15, 14). During the night following the battle of Gravelotte the French army withdrew within the line of the forts round Metz. The 6th Corps only was severely shaken, the 4th (the best in the whole army), though it had fought hard twice within forty-eight hours, losing nearly 30% of its strength, was still well in hand, and the 3rd, 2nd and Imperial Guards were almost intact. A fresh issue of ammunition and food was all the men needed to make them a thoroughly efficient fighting force comprising some 100,000 troops capable, with a resolute leader and sufficient staff, of crossing over to the right bank of the Moselle, overrunning the I. German Corps, the only one in their direct path, and then fighting their way across the communications of the II. and III. German Armies until they regained touch with the French railways to the south-west about Troyes.

The mere fact of the effort being made would have given the battle of Gravelotte the moral effect of a victory, and the reaction in the German ranks from the feeling of over-confidence, which had mastered them after the early successes of Spichern and Woerth, must have had most far-reaching consequences.

On the 15th of August the German forces began the investment of Metz, however, under cover of the forts, and set about the reorganization of his troops in the most leisurely manner. The Metz forts, though neither sufficiently armed nor even completely finished in some cases, were nevertheless, with their deep ditches and self-protecting bastion trace, far too formidable for any field army to attempt without the aid of a siege train of some 200 guns, which for the moment were not available. Of this fact the Germans were well aware, and hence they decided from the first to reduce the place by hunger, calculating that with the extra 150,000 men thrown back upon the fortress, its food supply could last them many years. On the morning of the 15th the German army was far too exhausted for further efforts. Except the I. Corps, which had been summoned overnight from its position about Courcelles towards the battlefield of Gravelotte and had almost reached the Moselle before this move could be counterordered, the remainder kept their places of the previous night, only following the French retreat with a screen of outposts. They were sufficiently occupied in collecting the wounded and clearing up the confusion resulting from an accumulation of trains and transport in the defiles of Gorze and about Novoâeau. No further movement could have taken place that day. In the course of the afternoon of the 15th the royal headquarters, creating a new army under the crown prince of Saxony (Guard, IV. and XII. (Saxons) Corps) for field operations towards the Meuse, assigned the remainder of the II. Army, and the whole
of the I, to Prince Frederick Charles as commander-in-chief of the army of investment. This brought the strength of his command up to eight corps, numbering some 220,000 men; an enormous mass to be handed over; and a vast sweep of supplies by the operations of the preceding week, and with only one railway line, terminating at Courcelles, to depend upon.

For the moment the chief care of the Prince was to guard against an attempt of the French army to break out to the westward. The I. Army Corps with Kummer's Landwehr division (which arrived during the night of the 19th-20th of August) were to occupy a position to cover the rail head at Courcelles-Rémilly, and the remainder were disposed in the following order: The X. Corps was on the north, with a bridge head at Haucourt-sur-Moselle, the II., VIII., and VII. along the eastern slopes overlooking the Moselle valley, the latter having also a fortified bridge head at Ars-sur-Moselle. The III. and IX. were cantoned almost on the battlefield of the 18th, between Caulre Farm and Ronceux, ready to move off to the left and support the X. Corps in the event of an attempt on the part of the French to break out towards Thienville.

The positions were fortified with a light outpost line, behind which was drawn a main position on which every art of the engineer was expended. Ample arrangements were made for obtaining and circulating intelligence, and all lateral communications were improved and supplemented to the utmost. A light field-railway from Rémilly to Pont à Mousson (14 m.) was also put in hand, but progress on this was very slow. The water-supply of the town was promptly interrupted, but the river water was quite drinkable.

Meanwhile, the French in Metz had been diligently at work. There was no real deficiency of ammunition and stores in the fortress, and provisions for forty days were reported in hand. Bazaine was still in communication with the outside world, though return messages came in sparingly. On the afternoon of the 25th he decided to break out to the northward by the right bank of the river, and orders to this effect were duly issued. Many delays arose in their execution, and it was not till 2 p.m. on the 26th that the troops were formed up ready for action. But at the last moment the marshal wavered. Calling a council of war on the heights of Fort St Julien, he asked the opinion of his subordinates, who were unanimously against the proposed sortie, principally because the artillery "had only ammunition enough for a single battle". Besides, the Germans had long since become aware of the movement in progress, and all chance of surprise was past. It was also raining very heavily. Accordingly the scheme was abandoned.

On the 29th of August Bazaine received a despatch, dated the 27th, from MacMahon, according to which his army should have been at Stenay on the Meuse and farther to the south by the 30th. The marshal accordingly determined to renew the attempt of the 26th, and orders—a repetition of the orders of the previous occasion—were issued.

At this moment (Aug. 31) the positions of von Manteuffel's command (I. Corps and 3rd Landwehr division) were most dangerously extended, and a surprise at daybreak might have had far-reaching results. But the habit of excessive bugling and hand-playing betrayed the French design even before daybreak. Not until 1:30 p.m. was the concentration completed, and Bazaine again assembled his commanding officers to give them their final instructions. This time he adhered to his decision, and about 4 p.m. the attack opened (battle of Servigny or Noisseville); but his opportunity had been allowed to slip, and though his first onset overwhelmed the German outposts, their main line held good, and masses of guns unliming over a front of some 4 m. rendered all further attempts to break the German cordon abortive. Firing only ceased as darkness fell, and next morning the fighting was again renewed. But while the French army was disheartened, it was obvious that what they had failed to do by surprise was hopeless now that twenty-four hours had been given in which the Germans could make counter-preparations. Therefore about noon a general retirement under the guns of the forts took place, and the last serious hope of the French army had vanished. Some 120,000 men with 528 guns had been engaged against 60,000 Germans with 222 guns, and had been beaten off with a loss of 3500 men. The Germans had lost about 3000.

The investment now resumed its regular course. The Germans, secure in the strength of their position on the left bank of the Moselle, drew more troops over to the right, and added to their defences and communications. The idea was even mooted of damming up the river near Haucourt, and thus flooding the whole of the civil population of Metz; but it was opposed by civil engineers, who were sent from Germany, reported against the proposal.

As time wore on the conditions in Metz and the surrounding camps became deplorable. The hospitals and private houses had been crowded with wounded from the first, and now, owing to the persistent wet weather, smallpox and dysentery became epidemic. Towards the close of September rations had to be reduced, and the troops began slaughtering the cavalry horses for food. Probably to cheer the men by a semblance of activity, Marshal Bazaine adopted a sortie of diversionary march on the 1st of October in the direction of Ladorchamps, and fighting continued into the 2nd, but without prospect of success, and the profound depression following on defeat sent up the sick list rapidly. One other sortie towards Neisseville followed on the 7th, the alleged reason for which was the hope of obtaining provisions in the neighbouring villages. But it was beaten off with the utmost ease by the investing troops, who were well fed and cared for; and as by this time even the gun-teams had followed the cavalry horses to the slaughter-house, the French army as an army—i.e. a combination of the three arms—had ceased to exist. On the recognition of this fact negotiations for the capitulation of Metz were begun on the 13th of October, and on the 14th the Army of the Rhine surrendered. Had it held out even forty-eight hours longer events before Paris and Orleans might have taken a different turn.

The investment of Metz had lasted 54 days, and the death-roll of the civil population had risen to 3587 against 1200 in the corresponding period of a normal year. The army itself had only lost from sickness 2600 men, or barely 2 1/2% of its full effective.

Meulens being a town of northern France, in the department of Seine-et-Oise, 6 m. E. of Versailles by rail and about 4 m. S.W. of Paris. Pop. (1906), 6979. The remains of a castle (17th century) burned during the siege of Paris in 1871 have since been adapted as an observatory. Its terrace commands a fine view of Paris. The handsome Galliera Institutions, on the hill of Fleury, were founded by the duchess of Galliera for the reception of aged persons and orphans. The buildings were completed in 1885, at a cost of £360,000. The town has a monument of Rabalais, who was cure there in 1555, and manufactured munitions of war for the artillery, and in the neighbouring park of Chalis is the Government military ballooning establishment. In the 16th century the cardinal, Charles of Lorraine, built at Meudon a magnificent chateau, which was destroyed in 1803. The present remains belong to a building erected by the dauphin, son of Louis XIV. The wood of Meudon lies for the most part to the west of the town.

Meulen, Antony Francis van der (1634-1693), Flemish painter, born in Brussels, was called to Paris about 1666 by Colbert, at the instance of Le Brun, to fill the post of battle painter to Louis XIV. His paintings during the circulating Flanders (1667) so delighted Louis that from that date Van der Meulen was ordered to accompany him in all his expeditions. In 1673 he was received into the French Academy, attained the grade of councillor in 1681, and died full of honours in Paris in 1690. He is best represented by the series of twenty-three paintings, mostly executed for Louis XIV., now in the Louvre. The show that he always retained his Flemish predilections in point of colour, although his style was modified by that of the French school.
MEUNIER—MEUSE

MEUNIER, CONSTANTIN (1831-1905), Belgian painter and sculptor, was born at Etterbeek, Brussels. His first exhibit was a plaster sketch, "The Garland," at the Brussels Salon in 1851. Soon afterwards, on the advice of the painter Charles de Groux, he abandoned the chisel for the brush. His first important painting, "The Salve Deo Rex" (1857), was followed by a series of paintings including "A Trappist Funeral" (1866), "Trappists Floughing" (1863), in collaboration with Alfred Vervée, "Divine Service at the Monastery of La Trappe" (1871) and episodes of the Peasants' War (1878). About 1880 he was commissioned to illustrate those parts of Camille Lemoine's description of Belgium in Le Tour du monde which referred to miners and factory-workers, and produced "In the Factory," "Smithery at Cockeir's," "Melting Steel at the Factory at Seraing" (1882), "Returning from the Pit," and "The Broken Crucible" (1884). In 1882 he was employed by the government to copy Pedro Campana's "Descent from the Cross" at Seville, and in Spain he painted such characteristic pictures as "The Café Concert," "Procession on Good Friday," and "The Tobacco Factory at Seville" (Brussels Gallery). On his return to Belgium he was appointed professor at the Louvain Academy of Fine Arts. In 1885 he returned to stationary and produced "The Puddler," "The Hammerer" (1886), "Firedamp" (1889, Brussels Gallery), "Ecce Homo" (1891), "The Old Mine-Horse" (1891), "The Mower" (1892), "The Glébe" (1892), the monument to Father Damien at Louvain (1893), "Puddler at the Furnace" (1893), the scheme of decoration for the Botanic Garden at Brussels in collaboration with the sculptor Charles van der Stappen (1893), "The Horse at the Pond," in the square in the north-east quarter of Brussels, and two unfinished works, the "Monument to Labour" and the Zola monument, in collaboration with the French sculptor Charpentier. The "Monument to Labour," which was acquired by the State for the Brussels Gallery, comprises four stone las-reliefs, "Industry," "The Mine," "Harvest," and the "Labourer"; four bronze statues, the "Sower," the "Smith," the "Miner," and the "Architect"; and bronze plaques of Maternity, Meunier died a Bruxellite in the 4th of April 1905.

MEURICE, FRANÇOIS PAUL (1818-1903), French dramatist, was born in Paris on the 7th of February 1818. In 1848 he became the editor of the Événement, founded by Victor Hugo, and in 1886 he was one of the promoters of the Rappel, a journal on similar lines. He was the literary executor of Victor Hugo, and edited his works (1880-1883). In collaboration with Auguste Vacquerie and Théophile Gautier, he produced Rabelais (1842), a play in imitation of Shakespeare, and in 1843 an imitation of the Antigone; and with Alexandre Dumas a Hamlet (1854), Puddler at the Furnace (1856), the scheme of decoration for the Botanic Garden at Brussels in collaboration with the sculptor Charles van der Stappen (1893), The Horse at the Pond, in the square in the north-east quarter of Brussels, and two unfinished works, the Monument to Labour and the Zola monument Commissioned by the State for the Brussels Gallery, comprises four stone las-reliefs, Industry, The Mine, Harvest, and the Labourer; four bronze statues, the Sower, the Smith, the Miner, and the Architect; and bronze plaques of Maternity, Meunier died a Bruxellite in the 4th of April 1905.

MEURISIUS [JOHANNES VAN MEURS] (1579-1639), Dutch classical scholar and antiquary, was born at Loosduinen, near the Hague. He was extremely precocious, and at the age of sixteen produced a commentary on the Cassandra of Lyco-phron. In 1610 he was appointed professor of Greek and history at Leiden, and in the following year historiographer to the states-general, and governor of the city of Gorinchem of his country, who welcomed the offer (1625) of Christian IV of Denmark to become professor of history and politics at Sorø, in Zealand, combined with the office of historiographer royal. He died at Sorø on the 20th of September 1639. Meurisius was the author of classical editions and treatises, many of which are printed in J. F. Gronovius's Thesaurus antiquitatum graecarum. Their lack of arrangement detracts from their value, but they are a storehouse of information, and Meurisius does not deserve the epithets of "pedant" and "ignoramus" which Scaliger applied to him. Meurisius also wrote on the troubles in the Netherlands and the history of Denmark.

MEURTHE-ET-MOSELLE, a department of north-eastern France, formed in 1871 out of those parts of the old departments of Meurthe and Moselle which continued French. Before 1790 it belonged to Lorraine, or to one or other of the bishoprics of Toul, Metz and Verdun. Pop. (1906), 717,520. Area 2,256 sq. m. It is bounded E. by Lorraine, N. by Belgium and the Meuse, W. by the department of Luxembourg, W. by the department of Meuse, and S. by that of Vosges. Meurthe-et-Moselle is of a hilly character, the highest elevation, the Grand Rougimont (2,041 ft.), being in the Vosges. The valley of the Moselle runs through it from south to north. Extensive forests, the chief of which is the Forest of Haye, are found in the south-western region. Only a small part of the drainage of Meurthe-et-Moselle flows into the Meuse, by far the greater part reaching the Rhine by way of the Moselle. The principal affluents of the Moselle are the Madon and the Orne on the left, and on the right, besides the Meurthe, the Selle, which in one part of its course forms the boundary of Alsace-Lorraine. The principal tributary of the Meuse within the department is the Chiers. Climatically Meurthe-et-Moselle belongs to the Vogisan region, and has hot summers and severe winters. Its mean annual temperature is between 48° and 49° F., being 2° lower than that of Paris (which has the same latitude). The annual rainfall averages between 28 and 32 in. The department possesses much fertile land, the chief crops being cereals and potatoes, together with clover, mangel-wurzels, tobacco, hops and beetroot. The vine is also cultivated, its best products being those of the Toul district. The most important products of the department are the apple, the walnut, the cherry and the plum. Of forest trees the oak and the yew-elm are most frequent in the west of the department, the beech and the fir in the Vosges. The French school of forestry has its seat at Nancy. The saltworkings (the chief of which lie between Nancy and St. Nicolas), and the iron-mines (round Nancy and Longwy) of Meurthe-et-Moselle are the most productive in France. Other important industries are the manufacture of boots and shoes, straw and felt hats, pottery, and tanning and brewing (at Tantonville). Cotton and wool spinning, and the manufacture of cotton goods, hosiery, embroidery, chemicals (at Dombasle, close to Nancy), soap, tobacco matches, crystal (at Baccarat, which has a population of 3,617), mirrors (Cirey), glass, army clothing and paper may also be mentioned. The department is served by the Eastern railway, the chief line being that from Paris to Strasbourg through Nancy. The main waterway is formed by the canal between the Marne and the Rhine. The canal communicates with the Moselle, which is navigable from Frouard downwards, and with the Eastern canal, which unites the Meuse and the Moselle with the Saône and the Rhone. The department constitutes the diocese of Nancy, has its court of appeal at Nancy, and forms a part of the district of the VI. army corps (Châlons-sur-Marne), and of the académie (educational division) of Nancy. There are 4 arrondissements (Nancy, Bricy, Lunéville and Toul), 29 cantons and 598 communes. The principal towns of the department are Nancy, the capital, Lunéville, Toul, Longwy, Pont-a-Mousson and St. Nicolas. Other places of interest are Prény, with ruins of an important stronghold (12th and 13th centuries) of the dukes of Lorraine; and Vaudémont, site of a famous monastery, with ruins of a stronghold of the 12th and 14th centuries.

MEUSE (Flem. Moes, Du. Maas), a river rising at Pouilly, in the department of Haute Marne, France. After passing through a great part of Belgium and Holland it flows into the Waal channel of the Rhine at Fort Loevenstein. A few miles below Gorinchem the Meuse, or Waal as it is then called, divides into two branches. The northern flows almost due west, and joins the Lek (Rhine) above Rotterdam, and enters the North Sea at the Hook of Holland. Ocean-going steamers for Rotterdam use, however, the New Waterway (Nieuwe Waterweg), a little north of the Meuse. The southern branch turns south, crosses the marsh of Biesbosch by the canalized channel of New Merwede, enters the Hollandsch Diep, and reaches the sea by the arms called Haringvliet and Krammen

Complete edition of his works by J. Lamé (1741-1763). See Van der Aa's Biographisch Woordenboek der Nederlanden (1869), and J. sundry, Hist. of Class. Scholarship (1908), ii. 311.
The length of the Meuse is nearly 560 m., of which 360 are navigable, and probably its traffic is only exceeded by that of the Rhine. Near Bazelaire it disappears under ground for a distance of over 3 m. The Chiers, the Semois, the Lesse, the Sambre, the Ourthe and the Roer are its most important tributaries. In Belgium it is canalized between Liège and Vise, and the Dutch are engaged on the same operation below Maestricht. The principal towns on the Meuse are: in France, Verdun, Sédan, Mézières and Givet; in Belgium, Dinant, Namur, Huy, Liège and Maastricht; in Holland, Maestricht, Roermond, Venlo, Dordrecht and Rotterdam.

**MEUSE**, a department of north-eastern France, formed out of a part of Lorraine (portions of the Three Bishoprics, and the Barois and Clermontois) and Champagne. Pop. (1906), 1,262,220. Area, 2,409 sq. m. It is bounded N. by Belgium and the department of Ardennes, E. by that of Meurthe-et-Moselle, S. by those of Vosges and Haute-Marne, and W. by those of Marne and Ardennes. About one-half belongs to the basin of the river Meuse, which is enclosed on the west by the wooded region of Argonne, on the east by the hills known as the Côtes de Meuse. On the north-east it is watered by the Orne, a tributary of the Moselle, and the Chiers, which runs by Montmédy to join the Meuse. The other half sends its waters to the Seine by the Aire, a tributary of the Aisne, both of which take their rise here, and by the Ornain, an affluent of the Saulx, the two last being tributary to the Marne. The highest elevation (1,388 ft.) occurs to the south-west, on the line of the ridge which separates the basin of the Meuse from that of the Seine. The heights gradually sink from south to north, but seldom fall below 1,000 ft. The hills of the Argonne similarly sink rapidly down to the valley of the Saulx, where the lowest level of the department (377 ft.) is reached. Its winters are less severe than those of the Vosges, but it is not so temperate as the Seine region. The average annual rainfall is about 30 in.

The chief crops of the department are wheat, oats, rye, barley, clover, potatoes and mangels-wurzels. The vine is cultivated to some extent, the best growths being those of Bar. The forests, occupying more than a quarter of the area, are principally of oak, and are rich in game, as are the rivers in fish. Basket-making is prosecuted in the Argonne. The mineral wealth of the department includes good freestone (Eeville, Lécourville). It has iron and steel works, wire-works, and manufactories of files, hardware and edge tools. Ligny-en-Barrois (pop. 4,870) manufactures scientific instruments. There are cotton-spinning, wool-weaving, and hemp, flax and jute factories, saw-mills, carriage works, leather manufactures, glassworks, paper-mills, distilleries and flour-mills. The department is served by the Eastern railway, the principal lines being that from Paris to Strasbourg through Bar-le-Duc and Commercy, that from Paris to Metz through Verdun, and the branch line of the Meuse valley. The chief waterways are the canal connecting the Marne with the Rhine and the Eastern canal along the Meuse valley; the two together have a length of 145 miles. Ecclesiastically the department forms the diocese of Verdun; it has its court of appeal at Nancy, and constitutes part of the district of the army corps of Châlons-sur-Marne, and of the educational division of Nancy. There are 4 arrondissements—Bar-le-Duc, Commercy, Montmédy and Verdun—28 cantons and 868 communes. The principal places in the department are Bar-le-Duc, the capital, Commercy, Verdun and St. Mihiel, which receive separate treatment. Other places of interest are Avioth, which has a church of the 14th and 15th centuries with a beautiful chapel of the 15th century adjoining it, and Rembercourt-aux-Pots with a fine church of the 15th century.

**MEUSE-LINE**, the chain of French forts along the passages of the Meuse between Verdun and Toul. The total length of the line is 31 m., and the forts d'arrêt are disposed along the fresh-water points between Verdun and St. Mihiel, Génicourt and Troyon; near St. Mihiel, Les Paroques (left bank) and Camp des Romains; and near Commercy—Louvigny, St. Aignant, Girouville and Jouy-sous-les-Côtes. Above the circle of the Toul defences there are barrier forts on the Upper Meuse at Pagny (la-Blanche-Côte) and near Neufchâtel; but these last are practically in second line, and between Toul and Epinal the frontier districts are designately left open. At Epinal the "Moselle-Line" begins. These lines form part of the defensive scheme adopted by France in 1873-1875. Their general design is that of the French fort illustrated in Fortification and Siegecraft, fig. 43, though they are varied in accordance with the site. **MEVANIA** (mod. Bevaux), an ancient town of Umbria, on the river Clitumnus and on the Via Flaminia, 8 m. W.S.W. of Forum Flaminii, 5 m. W. of Fulginium (Foligno), 738 ft. above sea-level. There are remains of a temple near the north gate, and of an amphitheatre built into the modern houses.

The wails, which have disappeared, were, according to Pliny (Hist. Nat. xxxv. 173), built of unbaked bricks. In 310 B.C. the consul Fabius broke the Umbrian forces here; but otherwise it is not mentioned until the 1st century A.D. In 69 the army of Vitellius awaited here the advance of Vespasian. Its position near the river and its white oxen are mentioned by Propertius, whose family belonged to Assium (mod. Assil) and after him by Silius Italicus, Lucan and Statius. The town was a **municipium**. The churches of S. Michele Arcangelo and S. Nicolò are Romanesque buildings of the 12th century.

**MEW.** (1) An imitative word, also spelled *miao*, representing the cry of a cat or of sea-birds. The name mew, usually sea-mew, as applied to the *Larus canus*, or common sea-gull, is, according to Skeat, also imitative. As the name of the sea-bird it appears in Du. *meeuw*, Ger. *Möwe*, and other languages.

**MEWANIA** (mod. Bevaux), an ancient town of Umbria, on the river Clitumnus and on the Via Flaminia, 8 m. W.S.W. of Forum Flaminii, 5 m. W. of Fulginium (Foligno), 738 ft. above sea-level. There are remains of a temple near the north gate, and of an amphitheatre built into the modern houses. The wails, which have disappeared, were, according to Pliny (Hist. Nat. xxxv. 173), built of unbaked bricks. In 310 B.C. the consul Fabius broke the Umbrian forces here; but otherwise it is not mentioned until the 1st century A.D. In 69 the army of Vitellius awaited here the advance of Vespasian. Its position near the river and its white oxen are mentioned by Propertius, whose family belonged to Assium (mod. Assil) and after him by Silius Italicus, Lucan and Statius. The town was a **municipium**. The churches of S. Michele Arcangelo and S. Nicolò are Romanesque buildings of the 12th century.

**MEWS.** (1610-1706), English royalist and divine, was born at Caundle Purse in Dorset on the 23rd of March 1610, and was educated at the Merchant Taylors' school, and at St John's College, Oxford, of which he was scholar and fellow. When the Civil War broke out in 1642 he joined the Royalist army, and, having been made a captain, was taken prisoner at Naseby; but he was soon released and in 1648 sought refuge in Holland. He became friendly with Charles I.'s secretary, Sir Edward Nicholas, and being skilful at disguising himself was very useful to the Royalists during the rule of Oliver Cromwell, undertaking two journeys to Scotland in 1653. Before this Mews had been made a fellow of King's College, and regaining his fellowship at Oxford after the Restoration, he became archdeacon of Huntingdon, vicar of St Mary's, Reading, and chaplain to the king; then, having obtained two other livings, he was made canon of Windsor, canon of St David's, and archdeacon of Berkshire. In 1667, when at Breda arranging peace between England and Holland, he was chosen president of St John's College, Oxford, in succession to his father-in-law, Dr Richard Baylie, afterwards becoming vice-chancellor of the university and dean of Rochester. Appointed bishop of Oxford and Wells in 1671, Mews resigned his presidency in 1673, and in 1684 he was elected bishop of Winchester, a position which this "old, honest cavalier," as Thomas Hearne calls him, filled until his death on the 9th of November 1706. The bishop is buried in Winchester cathedral. Mews lent his carriage horses to pull the cannon at a critical moment during the battle of Sedgemoor, where he was wounded whilst accompanying the royal army. He was, however, in sympathy with the seven bishops, and was only prevented by illness from attending their meeting; and as visitor of Magdalen College, Oxford, he supported the fellows in their resistance to James II., admitted their nominee, John Hough, to the presidency, and restored the ejected fellows in October 1688.
He took the oaths to William and Mary in 1689. In the absence of Compton, bishop of London, Mews took the chief part at the consecration of Tillotson as archbishop of Canterbury in 1691.

MEXBOROUGH is a market town, in the West Riding of Yorkshire, England, on the Don, r n. M. of Sheffield on the Great Central and Midland railways. Pop. (1891), 7734; (1901), 10,430. The Don affords water communication with the Humber. The church of St John the Baptist has Early English portions. The large industrial population is mainly employed in glass, pottery and iron works, and in the neighbouring stone-quarries. The Castle Hill is crowned with some fine earthworks of uncertain date.

MEXICO (Span. México, or Mexico) officially styled Estados Unidos Mexicanos and Repúblicas Mexicanas, a federal republic of North America extending from the United States of America southward to Guatemala and British Honduras, and lying between the Pacific Ocean on the west and the Gulf of Mexico and Caribbean Sea on the east. Its northern boundary was fixed by the Guadalupe-Hidalgo treaty of 1848 and the Gadsden treaty of 1853; it follows the Rio Grande del Norte from its mouth north-westward to lat. 31° 47' N., thence on that parallel W. 100 m., thence S. to lat. 31° 20' N., thence due W. to the 111th meridian, thence in a straight line (nearly W N W) to a point on the Colorado river 20 m. below the mouth of the Gila river, and thence, nearly due W., along the old line between Upper and Lower California to a point on the Pacific coast one marine league S. of the southernmost point of San Diego Bay; this line has a total length of 1810 m., of which the Rio Grande comprises 1136 and the land route 674 m. The boundary line with Guatemala, for a long time in dispute, was fixed by the treaties of 1882 and 1895. It is an arbitrary line and follows only two natural lines of demarcation—the Suchiate river from the Pacific coast to its source, and the Chixoy and Usama-cinta rivers from near the 16th parallel N.W. to a point on the latter 25 kilometres, S. of Tenosique (Tubosco). Between these rivers the boundary line is determined by the peaks of Tocancán, Buenavista and 1x2ul, and from the Usumacinta eastward it follows two parallels of latitude, one on the point of departure from that river, and the other, the longer, on that of 17° 49' to the British Honduras frontier. The boundary with British Honduras was determined by a treaty of 1893 and is formed in great part by the Hondo river down to the head of Chetumal Bay, and thence through that bay to the Boca Bacalar Chico—the channel separating Yucatán from Ambergris Cay. Geographically, Mexico extends from 4° 36' 42" N. (the mouth of the Gila river) to 32° 42' N. lat., and from 86° 46' 08" to 117° 07' 31" W. long. Approximately its greatest length from N.W. to S.E. is 1900 m., its greatest width 750 m., and its least width a little short of 140 m. In outline it is sometimes compared to a huge cornucopia with its small end curving S.E. and N. The interior curve formed by the Gulf of Mexico is comparatively regular and has a coast-line of about 1400 m. The Caribbean coast-line is about 327 m. long, exclusive of indentations. The outer curve facing the Pacific is less regular, is deeply broken by the Gulf of California, and stretches to about 4754 m., including that of the Gulf. The peninsula of Lower California (g.v.) lies parallel with the mainland coast and extends southward to about 22° 5' N. lat., a distance of nearly 760 m. The area of Mexico is commonly given by English authorities as 767,005 sq. m., by German statisticians as 1,987,201 sq. kilometers. (767,290 sq. m.), and by H. M. Bancroft, who quotes official figures, as 1,962,809 sq. kilometers. (757,607 sq. m.).

Physiography.—The surface features consist of an immense elevated plateau with a chain of mountains on its eastern and western margins, which extends from the United States frontier southward to the mountains of Tehuantepec and Santa Maria of the Gila (terras calientes) between the plateau and coast on either side; a detached, roughly mountainous section in the south-east, which belongs to the Central American Plateau, and a low sandy plain covering the greater part of the Isthmus of Yucatán. The peninsula of Lower California is traversed from north to south by a chain of high mountains, known as the Sierra Sur or the Sierra Madre Occidental. The slopes are precipitous on the east coast, but on the west they break down in hills and terraces to the Pacific. This range may be considered to represent a southward continuation of the Californian Sierra Nevada. The great chain of the Mexican Plateau is of Cretaceous origin. Its superstructure consists of igneous rocks of all descriptions with which the original valleys between its marginal ranges have been filled by alluvial deposits. The eastern and western, and other ranges are to be seen in the isolated ridges and peaks which rise above the level of the table-land, in some cases forming mountain peaks; otherwise the surface is singularly uniform in character and not very hilly. In the northern part of the country, the Valley of Mexico and Bolsón de Mapimí, once contained large bodies of water, of which only small lakes and marshy lagoons now remain. The highest point of the great plateau is to be found in the states of Mexico and Puebla, where the elevation is about 8000 m. Southward the slope is broken into small basins and terraces by transverse ranges, and is comparatively abrupt. Northward the slope is gentle, and is broken by several transverse ridges. At Ciudad Juarez (adjacently El Paso, Texas), on the northern frontier, the elevation is 3600 ft., which shows a slope of only 400 feet per mile. The Sierra Madre Occidental is a range of mountains on the north of the Isthmus of Tehuantepec, and the Sierra Madre Oriental is another range on the east of the Isthmus, with parallel mountain ranges both of them extending from the Sierra Nevada de Santa Marta on the western coast of Colombia, to the Sierra Nevada de Santa Cruz in the western coast of California, a distance of 1900 miles. They are separated by the Isthmus of Tehuantepec, which is a range of hills of 3000 ft. elevation. The Sierra Madre Occidental has still more lofty elevations, its culminating points being the Nevado de Colima (14,363 ft.) and Volcán de Colima (12,750 ft.) in the state of Jalisco. In the Sierra de Nayarit the Cerro Pinal rises to an elevation of 11,539 ft., and in the extreme south the Cerro del Leon, at 10,920 feet.

The sierras lying near the coast have an imposing appearance from the lowlands, but when seen from the plateau their general elevation is so dwarfed as to render them comparatively insignificant. The Sierra Madre Oriental consists of a prolongation of ranges to the south of the Isthmus of Tehuantepec, the Sierra Madre del Sur, with the fertile valley of Tehuantepec, to about 1000 feet above sea-level, and the Sierra Madre del Norte,战盟 one of many branches of the Sierra Madre Occidental, which branches stretch eastward to the coast of California. eastward to the coast of California. The eastern ranges are abrupt and difficult, and are a serious impediment to communication with the coast. Rising from the open plateau half way between this range and the city of Mexico is the isolated cone of Malinche, or Malintzin (14,636 ft.). Crossing the highest part of the Mexican Plateau is a broken series of ranges, which form the water-parting between its northern and southern slopes. To a part of these ranges has been given the name of Cordillera de Ahuacue, but there is no true cordillera across this part of Mexico. In a general sense these ranges may be considered part of the eastern branch of the Sierra Madre Occidental, which runs northward on the Gila branch of the U.S. boundary, or on the Gulf of California, and thence south by east direction. Southward the plateau is traversed by many low ranges and breaks down in terraces, forming one of the most fertile and attractive parts of the republic. Close to the capes of the Sierra Madre Occidental, the highest point is 13,078 ft. above sea-level, the Nevado de Tolulca (15,168 ft.) in a range which separates the valleys of Mexico and Tolulca, the Montes de las Cruces, that volute to the point of its base. This point, which is formed on the right angles to the axis of the other ranges, whose culminating points, some 20 m. south-east of the city, are the gigantic, snow-capped volcanoes of Popocatepetl (Smoking Mountain) and Ixtaccihuatl (beautiful woman). These mountains are now extinct, and no longer smokers. Their elevations, according to the Comisión Geográfica Exploradora, are 17,888 and 17,343 ft., respectively, that of Ixtaccihuatl being the higher by nearly 500 ft. In the characteristic, the transverse ridge just described having a large number of extinct volcanoes and at least three (Colina, Jorullo and Ceboruco) that are either active or semi-active. Colima was in a state of eruption as late as 1909.
Jorullo (1262 ft.) is said to date from 1759, when its cone was formed, and Celobreco (3700 ft.) in the territory of Tepic, shows occasional signs of activity. Near the coast in the state of Vera Cruz is San Martin, or Tuxte (7078 ft.), which has been quiescent since its violent explosion on the 2nd of March 1793. Orizaba is sometimes included among the semi-active volcanoes, but this is a mistake. It has been quiescent since 1856, and is now completely extinct. Earthquakes are common throughout the greater part of the republic, especially on the western coast. They are most violent from San Blas southward to the Guatemala frontier, and some of the Spanish towns on or near this coast have suffered severely. Chilpancingo, in Guerrero, was badly shattered in 1902, and in 1907, and in 1909 was reduced to a mass of ruins. The earthquake shocks of the 30th and 31st of July 1909 were unusually severe throughout southern Mexico, reducing Acapulco and Chilpancingo to ruins and shaking the city of Mexico severely. In Acapulco a tid wave followed the shock. Slight shocks, or temblores, are of almost daily occurrence. According to Humboldt's theory there is a deep fault in the earth's crust, just north of the 14th parallel through which at different periods the underground fires have broken at various points between the Gulf of Mexico and the Revillagigedo Islands. "On the supposition that these volcanoes, which are on the surface connected by a skeleton of volcanic rocks, are also united under the surface by a chain of volcanic elements in continual activity, may we account for the earthquakes which in the direction mentioned cause the American continent, from the Gulf of Mexico to the Pacific Ocean, to oscillate at the same time."

The lowland or tierra caliente region, which lies between the sierras and coast on both sides of Mexico, consists of a sandy zone of varying width along the shore-line, which is practically a tide water plain broken by inland channels and lagoons, and a higher belt of land rising to an elevation of about 3000 ft. and formed in great part by the debris of the neighbouring mountain slopes. On the Pacific coast there are places where the mountain spurs extend down to the coast, but in general this lowland region ranges from 30 to 40 m. in width, except in southern Vera Cruz, Tabasco, Campeche, and Yucatan, where it extends farther into the interior. The talus zone of this region, especially at elevations of 1000 to 3000 ft., is noted for its great fertility and the luxuriance of its vegetation.

The most important rivers in Mexico are the Rio Grande del Norte, the Rio Bravo, the Grijalva, the Usumacinta, and the Motagua. These rivers form the boundary between Mexico and the United States, and they flow into the Gulf of Mexico. The Rio Grande del Norte is the longest river in Mexico, and it flows through the states of Chihuahua and Durango. The Rio Bravo is the second longest river in Mexico, and it flows through the states of Tamaulipas and Veracruz. The Grijalva is the third longest river in Mexico, and it flows through the states of Tabasco and Campeche. The Usumacinta is the fourth longest river in Mexico, and it flows through the states of Chiapas and Guatemala. The Motagua is the fifth longest river in Mexico, and it flows through the states of Chiapas and Guatemala.

The Gulf of California is a large embayment of the Pacific Ocean, located on the west coast of Mexico. It is bounded on the north by the Baja California Peninsula, on the south by the mainland of Mexico, on the east by the Colorado River delta, and on the west by the Southern California coast. The gulf is separated from the Pacific Ocean by the Baja California land bridge, which is now in the process of forming a new land bridge between the two continents.

The Rio Colorado is a river that flows through the states of Baja California and Sonora, and it is the main source of water for the city of Mexicali. The river is about 300 miles long and it has a discharge of about 1500 cubic feet per second. It is an important source of water for agriculture and irrigation in the surrounding area.

The Gulf of California is a large embayment of the Pacific Ocean, located on the west coast of Mexico. The river is about 300 miles long and it has a discharge of about 1500 cubic feet per second. It is an important source of water for agriculture and irrigation in the surrounding area.
Tepic to the Pacific coast, with a total length of 540 m., celebrated for its deep canyons and waterfalls; the Rio de las Balsas, cr Mexicali, which flows south-west to the Gulf of California, with a course of 426 m.; the Yaqui, which rises in western Chihuahua and, after breaking through the northern ranges of the Sierra Madre Occidental, flows south-westerly across Sonora to the Gulf of California, with a course of 523 m. The islands of the Gulf archipelago are of no practical importance, but the islands of the Chiapas, within its course of 415 m., is the backbone of the Gulf of California, with a course of 340 m.; the Usuacurita, which is formed by the confluence of the rivers of the same name, are the best known of the lagoons on Chihuahua, with a course of 270 m. The country about the Laguna de Términos is low and flat, and is traversed in all directions by deep, sluggish streams. Many of the rivers crossing the lowlands bordering the Gulf have short navigable channels, the most important of which is the Pánuco and its tributaries. The Rio Grande is navigable for small vessels up to Matamoros (31 m.), and for smaller craft 65 m. farther. The Gulf coast rivers, however, are obstructed by bars over 200 ft. wide, from the mouths of the rivers, and their lagoons are the best known of the Gulf of Mexico—Texasco, Chalco, Xochimilco, Zumpango, Xaltocan and San Cristobal—which are probably the remains of a lake once occupying the site of modern Mexico City. Their surficial connections are all obliterated, and the several lagoons are slowly diminishing in area. Some of them, like Xochimilco, will eventually disappear. The largest, Texcoco, has an area of about 111 sq. m. (50 sq. km.), but it contains no water; it is a large enclosed basin that was a lagoon. Its surroundings are bleak and sterile, and its water brackish and polluted with the drainage of the neighbouring city for nearly four centuries. The other lakes are wholly different in character and situation, but they are all of the same lagoon type. A breakwater was built up by the Gulf current from 5 to 7 m. from the shore-line. Inside the present sandymound is a peculiar tide-water channel called the Rio Lagartos, which follows almost the whole northern shore of the island. The lake is famous for its white ibises, and discharges into the Pacific through the Santiago. On the lower terraces of Michoacan are Patzcuaro and Cuatitlan lakes, and elsewhere among the sierras are numerous other small bodies of water. Among the tide-water lagoons, of which there are many along the Gulf coast, the best known are the Laguna de Términos in Campeche, Tamahua in Vera Cruz, Madre (130 m. long), Pesqueria (21 m. long) and Chalcol (near Tampico) in Tamaulipas. All these lagoons are navigable by those of northern Vera Cruz and Tamaulipas, when connected and improved, will afford a safe inland route for some hundreds of miles along the coast. The northern lagoons, except for the lake near Tampico, are reached by the Gulf current, which penetrates their mouths. The southern lagoons, such as the Laguna de Términos, are not penetrated by the current, but they are usually shallow, sometimes swampy, and have no value for commerce.

The marked difference between the Gulf and Pacific coastlines of Mexico in regard to their minor indentations and harbours. The south-west part of the Gulf of Mexico is called the Gulf of Campeche (Campechay), but no distinction is necessary. This contains the ports of Tampico, Tuxpan, Coatzacoalcos, and Frontera on the rivers, and the ports of Campeche and Coatzacoalcos, however, have no particular watering places or breakwaters. The entrance of the Gulf of California, across the bars, is on the Gulf coast opens into a series of reefs, but the entrance for vessels of 30 ft. draught from the breakwater to the entrance for vessels of 9 ft. draught from the breakwater has remedied this defect and Vera Cruz is no longer considered a dangerous port. Campeche has a small artificial harbour, which is so silted up that vessels drawing 9 ft. must anchor half a mile off, and the town, although it looks like a large naval station, has only an open roadstead, and large vessels cannot approach its landing-place nearer than 6 m. On the east coast of Yucatan the shipping is protected from the inconstant winds by the breakwaters which have been constructed at Espiritu Santo, which afford good anchorages, and at the north end of the island of Cozumel the bay of Santa Maria offers an excellent harbour. The Pacific coast has several deep and well-protected harbours, but most of them are very small and difficult ranges of the Sierra Madre Occidental. There are two large indentations of the coast—the Gulf of Tehuantepec and California. The former is opposite the Gulf of Campeche, and possesses no distinguishing characteristics. The Gulf of California, on the other hand, penetrates the continent for a distance of 739 m., from south-east to north-west, with a maximum breadth of 190 m. Its area is usually restricted to the waters north of the latitude of Cape San Lucas, but it should be extended to the outer waters enclosed by a line from Cape San Lucas to Cape Corrientes. Its upper waters are not much navigated because of the aridity of its shores, but there are some small islands, and its northern entrance is south. The Gulf has a considerable number of islands, most of them near the northern coast, and several deep, well-protected harbours, of which the most important is the port of Mazatlan, in Sonora. It is connected with the inner Gulf by the harbours of Mazatlan, San Blas, Bandera, Manzanillo, Acapulco, Salina Cruz and Tonalá. Several of these are being improved.

The Mesozoic beds are of greater importance. The Triassic and Jurassic rocks, which are only in thin layers in most of the regions, have not been extensively explored. The Triassic consists of sandstones and clays, and the fossils found in them are chiefly plants, including Ganganopterus and Macrogeniaster, two characteristic genera of the Indian system; and limestones, which contain marine fossils. The Cretaceous rocks are a large surface layer in the formation of the country. They form the greater part of the Sierra Madre, and also constitute the great basement of the plateau. They contain many fossils, including Hippuritites and Ammonites. The sedimentary deposits of the Tertiary era do not occupy a very wide area. They occur, however, along the coasts, where they are marine, and also on the central plateau, where they are of lacustrine origin. But by far the most important of the Tertiary rocks are the volcanic lavas, agglomerates and ashes, which cover so much of the country. It is in the western half of the country that they were most fully developed, but towards the southern extremity of the plateau they spread nearly to the eastern coast. The eruptions are said to have begun with the ejection of syenites, which were successively followed by basalt and trachyte rocks, and finally by the basaltic agglomerates, which continued until the Cretaceous or the beginning of the Eocene period. In the Miocene period andesites of various kinds were erupted, while at the close of the Pliocene the great eruptions of basaltic lava penetrated Quaternary times and continue to the present day.1

deeply into the tropical half of the country, carry with them temperate and sub-tropical phenomena over much the greater part of the region. Above the plateau rise the marginal sierras, a few isolated peaks in the region of perpetual snow give to Mexico a considerable area of cold temperature. The Peninsulas of Yucatan and Campeche, on the eastern and southern sides of the Yucatan peninsula, respectively, are at high elevations. The plateau, rising steadily until the upper limit of the tropical region, called tierras calientes, is reached, where the climate is hot, unhealthy, as elsewhere in the forested coastal plains of tropical America.

The tierras calientes (hot lands) of Mexico include the two coastal zones, the Isthmus of Tehuantepec, the states of Tabasco, Campeche, Oaxaca. The mean temperature ranges from 77 to 82° F., seldom falling below 60°, but often rising to 105°, and the heat is oppressive. Above the plateau and in the valley of Mexico to and even above 10,000 ft. The rainfall is heavy in the south, except Yucatan, but diminishes gradually toward the north, until on the Pacific and Gulf of California coasts it almost vanishes. The rainfall is greatest on the south, except Yucatan, and large areas are covered with streams, swamps and lagoons, the abode of noxious insects, pestiferous feeders and dysentery. On the coast yellow fever epidemics appear at frequent intervals. The great fertility of these regions and the marvellous wealth of their forests are irresistible attractions to industrial and commercial enterprise, but their unhealthy and pestiferous character restricts their permanent occupation by man. The heavy rainfall on the Gulf coast, however, which reaches a maximum of 90 to 100 in. in the Huatusco district of Vera Cruz, causes the flooding of large marshes, which will make the plain very valuable for cultivation. The peninsula of Yucatan, whose general level does not rise above 130 to 200 ft. above the sea, consists almost wholly of an open, dry, calcareous plain. The temperature ranges from 82° to 88° F., with a very dry season here the arid belt between the mountains and the sea. The maximum temperatures in this region are 95° at Hermosillo and 110° at Guaymas. To a large extent the climate of Mexico is determined by vertical zones. According to H. H. Bancroft (Resources of Mexico, pp. 3-4), the tierras calientes, which include a coastal zone 30 to 40 m. wide, and the low-laying states already mentioned, rise from sea-level to an elevation of 1000 ft., or less, and have an annual rainfall of 5577 ft., and comprises the greater part of Coahuila, Nuevo Leon, San Luis Potosi, nearly half of Tamaulipas, a small part of the states of Tucuman, Chihuahua, and the Guaymas district of Lower California, a large portion of Guerrero, Jalisco, Sinaloa and Sonora, together with small parts of the inland states of Puebla, Mexico, Morelos and Michoacan. The mean annual temperature is about 75° F., and the annual rainfall from 55 to 60 in. It includes the upper mountains of the Mexican plateau, and which corresponds to the temperate regions of Central United States where frosts are very rarely experienced. Even here the high mountain temperatures are somewhat sub-tropical to the character in the country. In the sierras, above the tierras frias, which are not "cold lands" at all, are the colder climates of the temperate zone, suitable for cereals, grazing and forest industries, and, farther up, the isolated peaks which rise into the regions of snow and ice.

Speaking generally, the four seasons are clearly marked north of lat. 25° N. only. South of that parallel they merge in the estacion de estia in June, or rainy season, or estacion seca, or dry season, which prevails for the rest of the year. The rains generally begin on the east coast and gradually move north, the western coast of Mexico first receiving the greater part of the rainfall, and the winds, deprived of moisture, pass over the northern plateau without further precipitation. On the Pacific coast the belt of calm, known as the northern border, latitudes, crosses the northern parts of Lower California and Sonora, which accounts for their extreme aridity. The southern terraces of the plateau have no high mountain barriers between, but moist winds from the other side of the plateau have received an abundant rainfall in the wet season, especially during the prevalence of heavy "northerns" on the Gulf coast. The precipitation varies widely, that of the western side of the northern plateau (Coahuila) being 5 ft. in. on the other side of the same plateau, Mexico about 25 in., and that of the whole republic 59 in. Long droughts are common in many parts of the country, and on the hilly borders of the plateau the rains drain away rapidly, leaving but slight beneficial results.

Flora and Fauna.—The types of animal and vegetable life found in Mexico belong, in a general sense, to those of the northern temperate region, and those of the tropical regions of Central and South America. The great central plateau and its bordering lowlands form an intermediate territory, for which reason the tropical species extending northward along the coast to the United States, while the northern species have found their way to the southern limits of the plateau. The jaguar and puma have found their way to the food of birds in the mountains, bear and beaver have gone far southward on the plateau, and the buffalo was once found in large numbers on its more favoured northern plains. This intermingling of types does not apply to southern Mexico, where many of the genera and species found in the forested lowlands of the great Amazon basin.

Aside from its origin, the fauna of Mexico includes at least five species of monkeys, the jaguar, puma, ocelot (Felis pardalis), wolf, coyote, lynx, badger, otter (Lutra lutra), beaver, muskrat, bear, raccoon (Procyon), coati (Nasua), tapir, two species of peccary (Dicerotoalos), and the white-tailed deer (Odocoileus leucoryx), marten, several species of opossum (including a pigmy species of the Tres Marias islands), sloth, two species of ant bear (Myrmecophaga tridactylus and Cyclopes didactylus), armadillo (Dasypus novemcinctus), a small arboreal porcupine (Symendes mexicanus), the kinkajou (Cercoleptes caudivovulus), three species of deer—the white-tailed Cervus canadensis, the black-faced brocket (Odocoileus hemionus), and the white-tailed hog-deer (Axis minutus)—the Mexican black bear (Ursus americanus), the opossum, and several species of the raccoon-like family. Many species, ranging from the comparatively harmless boa-constrictor to the deadly "palaica" or "fer de lance" (Lachesis montezumae) and rattlesnake (Crotalus), of which there are several varieties. In addition to these many well known species, the government has introduced carp, brook trout and salmon trout.

The avifauna of Mexico includes most of the species of the tropical and subtropical areas. The most characteristic is the yellow-headed Chrysotis, parakeets (Conura canaria), macaws (ara macao and A. militaris), toucans, trogons, herons, egrets, ibis, spoonbills, boat-bills (Ciconia), ducks, pelicans, cormorants, several species of stilt, sandpipers, curlews, great egrets, Grallina, "Chachalacas" (Ortalis palpebrosa), woodpeckers, jays, cuckoos, "garapaneros" (Crotaphaga subcriophora), the ingenious weaver-bird (Icterus), and another species (Cassiodora), whose curious woven nests are sometimes seen from telegraph-wires, Scarlett-crowned flycatchers (Musciora mexicana), tanagers, mocking birds (called "zenzontal"), many other species. Mexico, however, is also one of the great bird-migratory areas, and perhaps, are the humming-birds, of which there are more genera and species, each one distinct in form and colour. They are called "hؤlitas" (spikelet) by the Aztecs, and "colibri," "chupan- pinos," and "chupapinos," and "moscas" (fly-bird) by the Spanish-speaking Mexicans. These descriptive names are highly poetic, as also that of the Portuguese, "mucury," some of which are long-lived, like the "aurora" of North America, and others are "colibri" and "pollo," "aurora" and "pollo," respectively, and thrusts his long bill into flowers in search of insects instead of honey. Mexico is credited with a great variety of song-birds, but these are to be found chiefly in the partly forested country of the northern states. Mexico is also admirably rich in birds of varied and gorgeous feathering. The wonders of plumage of the "quetzal" (Trogon resplendens) was, it is said, reserved for the gods. The great plume of the "quetzal" (Trogon resplendens) was, it is said, reserved for the gods.
by the Aztec rulers for their own exclusive use. Of the indigenous 
birds, the turkey has been fully domesticated, and the musk-duck 
and the asar are among the many species that have been 
learned on the coasts of Lower California, where certain islands in the 
arid belt are frequented at night by countless numbers of them. It 
should be added that many of the migrating birds of North America 
pass through this region.

The insect fauna of Mexico covers a very wide range of genera 
and species which, like the other forms of animal life, is largely 
modified by the climatic and geographical conditions. About 
321 species of fleas are recorded from the flora of this region, 
and of these about 200 are native species. Of the various kinds of 
mosquitoes, 45 species are known to occur in Mexico, and 8 are 
found in the higher mountainous regions. A number of these, 
which are also found in the United States, are the most 
important pests of the region. Among these the commonly 
found yellow fever mosquito, Anopheles quadrimaculatus, 
and the African species, A. gambiae, are the best known.

The climate of Mexico is one of the most interesting of any country.

The climate of Mexico is one of the most interesting of any country.

The Mediterranean climate is found along the coast of the Gulf of 
Mexico, and of the Pacific coast, and the climate of the high 
plateau, which is characterized by very cold winters and 
summer air masses, is one of the most interesting of any country.

Mexico has long experienced destruction of its forests, not only for industrial purposes but through the careless burning of grassy areas. The denuded mountain slopes and plateaus of southern Mexico are due to the clearance of the native inhabitants and the subsequent erosion of the tropical forest for their Indian corn fields, and then left to the erosive action of the tropical rains and subsequent occupation by coarse grasses. Fire was generally used in clearing the land, and the result that these cleared vegetation was ultimately killed and their fertility destroyed. In the valleys of some of these denuded slopes oak and pine are succeeding the tropical species where fires have given them a chance to get a good foothold.

Population.—According to the census of 1900 the population of Mexico numbered 13,627,259, of which less than one-fifth (19%) were classed as whites, 38% as Indians, and 43% as mixed bloods. There were 57,597 foreign residents, including a few Chinese and Filipinos. Since then the Japanese have acquired an industrial footing in Mexico. Under the constitution of 1824 all race distinctions are abolished, and these diverse human elements are nominally free and equal. For many years, however, the Indians remained in subjection and were subject to the same labor activities as their native country. Since about 1866, spurred on by the consciousness that one of their own race, Benito Juárez, had risen to the highest positions in the gift of the country, they have taken greater interest in public affairs and are already making their influence felt. In southern Mexico the Zapotecas furnish schoolmasters for the village schools. Peonage, however, is still prevalent on many of the larger estates, and serious cruelties are sometimes reported.

The government itself must be held partly responsible, as for the transportation of the mountain-bred Yaquis to the low tropical plains of Yucatán (see Herman Whitaker's The Plautier, 1903), but the influence of three and a half centuries of slavery and peonage cannot be shaken off in a generation.

According to Humboldt, the census of 1820 gave a total population of 6,122,554, of which the whites had 18%, the mestizos 22% and the Indians 60%. The census of 1895 increased the whites to 22%, which was apparently an error, the mixed bloods to 47%, and reduced the Indians to 31%. It is probable that the returns have never been accurate in regard to the mixed bloods and Indians, but it is the general conclusion that the Indians have been decreasing in number, while the mixed bloods have been increasing. Neglect of their children, insanitary habits and surroundings, tribal intermarriage and peonage are the principal causes of the decreasing Indian population. Recent observers, however, deny the assertion that the Indians are now decreasing in number except where local conditions are exceptionally unfavourable. The death rate among their children is estimated at an average of not less than 50%, which in families of five and six children, on an average, permits only a very small natural increase. The larger part of the population is to be found in the southern half of the republic, owing to the arid conditions prevailing in the north. The unhealthfulness of the coastal plains prevents their being thickly populated, although Vera Cruz and some other states return a large population. The most favourable regions are those of the tierras templadas, especially on the southern slopes of the great central plateau which were thickly populated in prehistoric times.

The dissimilar races that compose the population of Mexico have not been sufficiently fused to give a representative type of which, it may be assumed, will ultimately be that of the mestizos. Mexico was conquered by a small body of Spanish adventurers, whose success in despoiling the natives attracted theider a large number of their own people. The discovery of rich deposits of gold and silver, together with the coveted commercial products of the country, created an urgent demand for labourers and led to the enslavement of the natives. To protect these adventurers for itself the largest possible share in these new sources of wealth, the Spanish crown forbade the admission of foreigners into these colonies, and then harassed them with commercial and industrial restrictions, burdened them with taxes, strangled them with monopolies and even refused to permit the free emigration thither of Spaniards. Out of such adverse conditions has developed the present population of Mexico. It was not till after the middle of the 19th century that a long and desperate resistance to foreign intervention under the leadership of Benito Juárez infused new life into the masses and initiated the creation of a new nationality. Then came the long, firm rule of Porfirio Diaz, who first broke up the organo, which infested the land, and then sought to raise Mexico from the state of discredit and disorganization into which it had fallen. Suspicion and jealousy of the foreigner is disappearing, and habits of industry are displacing the indolence and lawlessness that were once universally prevalent.

The white race is of Spanish descent and has the characteristics common to other Spanish-American creoles. Their political record previous to the presidency of Porfirio Diaz was one of incessant revolutionary strife, in which the idle, unsettled half-breeds took no unwilling part. The Indian elements in the population is made up of several distinct tribes, the Aztec or Mexican, Mixteca-Zapotoca, Maya or Yucateco, Otomi or Othomi, and in smaller number the Tonotac, Tarasco, Apache, Matlânzingo, Chontal, Mixe, Zoque, Guaicuá, Opata-Pima, Tapijulapa, Seri and Huavi. As the tendency among separated tribes of the same race is to develop dialects and as habitat and customs tend still further to differentiate them, it may be that some of these smaller families are branches of the others. In 1863 Don Manuel Orozco y Berra found no fewer than 51 distinct languages and 69 dialects among the Indian inhabitants of Mexico; of these he noted 62 extinct idioms—making a total of 152 idioms, each representing a distinct tribe. Thirty-five of these languages, with 69 dialects, he succeeded in classifying under 11 linguistic families. A later investigator, Don Francisco Belmar (Lenguas indígenas de Mexico, Mexico, 1903), has been able to reduce these numerous idioms to a very few groups. None of them were written except through the use of ideographs, in the making of which the Aztecs used colours with much skill, while the Mayas used an abbreviated form, or symbols.

The Aztecs, who called themselves Mejica or Mexicans after the old state of Mexico City, which once formed the great table-land of Mexico, belong to a very large family or group of tribes speaking a common idiom called Nahua or Nahoa. These Nahua-speaking tribes were called the Nahuahtlaca, and compose a little more than one-fourth of the present Indian population. They inhabit the western Sierra Madre region from Sinaloa southward to Chiapas, the higher plateau states, which region was the centre of their empire when Cortés conquered them, and parts of Vera Cruz, Tabasco, Oaxaca, Morelos, Aguascalientes and San Luis Potosí. They were energetic and warlike and evidently had not reached the zenith of their power when Cortés came. They had been oppressed on the same plateau by the Chichimecas, possibly of the same race, who were conquered by the Aztecs sometime in the 15th century after a supposed occupation of the territory about 400 years. The characteristic civilization of prehistoric Mexico, however, antedates both of these periods.

An Abinglong race called the Toltecs is said to have occupied Vera Cruz and Tabasco and to have extended its empire westward on the plateau to and perhaps beyond the present capital. They were the builders of the pyramids of Cholula and Teotihuacan, near the city of Mexico, and of Papantla, Huatusco and Tuxpan, in Vera Cruz. One of their towns was Tula (now Tula) 50 m. north of the national capital, and it is not improbable that the people of Cholula, Texcoco and Tlacaxtla at the time of the Spanish invasion were occupying the sites of older Toltec towns. There has been much discussion in regard to the origin of the Toltecs, some assuming that they were a distinct race, and others that they belonged to the Nahuahtlaca. Another and perhaps a better supposition is that they belonged to the Maya group, and represented a much earlier civilization than that of the builders of Palenque, Quirigua and Copan. Confirmatory.
MEXICO

POLITICAL DIVISIONS

Evidence of this is to be found, not only in the character of its constructions, but in the circumstance that a tribe closely akin to the Mayas (the Huastecos) still occupies a retired mountain valley of Vera Cruz, entirely separated from their kinsmen of the south, and that a dialect of the Maya language is still spoken in northern Vera Cruz. There is evidence to show that the Aztecs adopted the civilization of the Toltecs, including their religion (Quetzalcoatl being the god of the Toltecs and Mayas), calendar and architecture. Perhaps the most remarkable of the Mexican races are the Mayas, or Maya-Quiché group, which inhabit the Yucatán peninsula, Campeche and parts of Tabasco, Chiapas, and the neighboring states of Central America (q.v.). The remarkable ruins of Palenque, Uxmal, Chichenitza, Lorillard, Ixincé, Tikal, Copan and Quirigua, with their carved stonework and astonishing architectural conceptions, show that they had attained a high degree of civilization. They were agriculturists, lived in large, well-built towns, cultivated the mountain sides by means of terraces, and had developed what must have been an efficient form of government.

The Mixteca, or Mixtecs, and Zapotecas, who occupy the southern slopes of the central plateau, especially Puebla, Morelos, Oaxaca and Guerrero, form another distinct race, whose traditional history goes back to the period when the structures now known as Mitla, Monte Alban, Xochicalco and Zaachila were built. Their prehistoric civilization appears to have been not inferior to that of the Mayas. They were an energetic people, the natives of the Aztecs, and are now reverting from their long subjection to Spanish enslavement more rapidly than any other indigenous race. The Otomis comprise a large number of tribes occupying the plateau north of the Anahuac sierras. They are a hardy people, and are the least civilized of the four principal native races.

The Totones inhabit northern Vera Cruz and speak a language related to that of the Mayas; the Taracos form a small group living in Michoacán; the Matlantzingos, or Matlatzincas, live near the Taracos, the savage Apaches, a nomadic group, of tribes ranging from Durango northward into the United States; the Opatza-Pima group, inhabiting the western plateau region from Sonora and Chihuahua south to Guadalajara, is sometimes classed as a branch of the Nahua group; the Seris, a very small family of savages, occupy Tiburon Island and the adjacent mainland of Sonora; and the Guiacuros, or Yumas, are to be found in the northern part of the peninsula of Lower California. In southern Mexico, the Chontales, Tajipulapas, Mixes and Zoques inhabit small districts among and near the Zapotecas, the first being considered by Belmar a branch of that family. The Huativas inhabit four small villages by the mountain of the Tepanatepe, and have been classed by Belmar as belonging to the Maya stock. The census of 1895 gave these Indian races an aggregate population of nearly 4,000,000, of which nearly 3,450,000 belonged to the first four groups. These of the four had made important progress toward civilization. Some of the others had likewise notable progress, among which were the Taracos, Totones and Zoques.

The builders of Casas Grandes (q.v.), in Chihuahua, evidently belonged to this small tribe of Arizona and New Mexico. As for the builders of Quemada, in Zacatecas, nothing positive is known. The ruins apparently are of an earlier period than those of Mitla and Xochicalco, and have no inscriptions or architectural decorations, but the use of dressed stone in the walls, rather than adobe, warrants the conclusion that they belonged to the civilization of southern Mexico.

From the records made at the time of the Spanish conquest, and from the descriptions given by the conquerors in the histories of Mexico, it is certain that the Indians lived in substantial houses, sometimes using dressed stone, inscriptions and ornamental carvings on the more pretentious edifices; they cultivated the soil, raised crops, perhaps, and produced enough to make it possible to live in large towns, they made woven fabrics for dress and hangings, using colours in their manufacture; they were skilful in making and ornamenting pottery, in making gold and silver ornaments, and in featherwork; they used the fibers that Nature lavishly provided in weaving basketwork, hangings, mats, screens and various household utensils. Copper was known to them, and it is possible that they knew how to make cutting instruments from it, but they generally used stone axes, hammers and picks, and their most dangerous weapon was a war-club into which chips of volcanic glass were set. Many of these primitive arts are still to be found in the more secluded districts, and perhaps the best work in pottery moulding in Mexico to-day is that of uneducated Indian artists.

Of the half-breed element which has become so important a part of the Mexican population, no safe estimate can be made. Education, industrial occupation, commercial training and political responsibility are apparently working a transformation that was once known chiefly for its debasing and crime-instincts, and many of the leaders of modern Mexico have sprung from this race. Settled government, settled habits, remunerative employment and opportunities for the improvement of their condition are developing in them the virtues of the two parent races. Brigandage was formerly so common that travel without an armed escort was extremely dangerous; under President Diaz, however, not only has such lawlessness been repressed but the brigands themselves have been given regular employment as rural guards under the government. This class is also furnishing the small traders of the towns, overseers on the plantations and public works, petty officials, and to some extent the teachers and professional men of the provincial towns.

Political Divisions.—The Republic of Mexico is politically divided into 27 states, one federal district, and three territories. The states are generally subdivided into districts (districts) or partidos, and these into municipios (municipalities) which correspond to the townships of the American system. The state of Nuevo Leon, however, is divided into municipios only, while some other states use entirely different titles for the divisions, the larger being described as departamentos, cantons and municipios, and the smaller as partidos, directorias and vecindarios rurales. The Federal District consists of thirteen municipalities. The territory of Lower California is divided into two large districts, northern and southern, and the latter into partidos and municipios—the larger divisions practically forming two distinct territories.

The states and territories, with their areas, capitals and populations, are as follows:

</table>

In the islands of the Mexican empire, the population was estimated at 278,000 in 1890.
The area and population of Yucatán include those of the territory of Quintana Roo, which formed part of that state at the time of the census.

Baja, or Lower California, is divided into two districts for administrative convenience. The Distrito del Norte is credited with a population of 7583 and has its capital at Ensenada (pop. 1026); the Distrito del Sur has a population of 49,041 and has its capital at La Paz.

Tepic was detached from the north-west part of Jalisco and organized as a territory in 1889.

Quintana Roo was detached from the state of Yucatán in 1902 and is now the federal district of the government.

The principal cities of Mexico, other than the capitals above mentioned, are as follows, the populations being those of 1900 except when otherwise stated:

1. Tampico, on the Gulf of California, has a population of 19,792.
2. Mazatlan, which was wrecked by the earthquake of 1900; Carmen, or Laguna de Términos (about 6000), a thriving commercial town and port on the Gulf of Campeche; Celaya (27,192), a little port on the Gulf of California.
3. Ciudad Guzman, or Zapotlán (about 17,500), an interesting old town of Jalisco; Cholula (about 9000), an ancient native town of Puebla, widely known for its great pyramid, Comitán (9376), the commercial centre of Chiapas; Cordoba (7974 in 1895), a picturesque Spanish town in the sierras of Vera Cruz; Cuautla (6269), the centre of a rich sugar-producing district of Morelos; Guaymas (8636), a flourishing port on the Gulf of California.

The capital of Mexico is the Federal District of Mexico City, which contains the centre of the capital (9316), which extends to the Pacific at Coatzacoalcos (officially Puerto Mexico) on the Gulf coast to Salina Cruz on the Pacific coast, and has been under construction many years. The railway was first completed in 1894, but light and defective construction, together with lack of maintenance, etc., has delayed and impeded its usefulness. To correct these defects the line was completely rebuilt and terminal ports constructed. In 1900 the ports were ready to receive large ocean steamships, and the coast traffic had increased to over 250,000 tons of sugar for New York. The highest point on the line (Chivela Pass) is 735 ft. above sea-level. The railway has been built by the Mexican government as a transcontinental route for international commerce. Its final construction together with that of its two ports were executed by S. Pearson & Sons Ltd., of London, who also undertook the working of the line when open. It was estimated in 1899 that the total cost of the railway and ports when completed would amount to 85,000,000. The total length of the Mexican lines is 7924 ft. Since the railway from Santa Luceria (109 m. from Salina Cruz) with the Vera Cruz and Pacific railway which gives an all-rail connection with Vera Cruz and the Mexican Pacific coast, where the line joins the Gulf being 250 m. According to the President's Message of April 1909, there were 14,857 m. of railway in operation, of which 11,831 m. belonged to or were controlled by the government. It is the evident policy of the government to transfer the line to Mexico by the national railways by private monopolies, and this is effected by state ownership of a controlling share in most of the trunk lines.

Mexico is well provided with a railway network, which is larger than that of any other country.

A British consul report for 1904 stated that Mexico City and Torecon only were using electric traction, but that Guadalajara, Monterrey, Aguascalientes, Lagos, Colima, Vera Cruz and San Luis Potosi were using horse trams.

The first transcontinental line was opened in 1879 between the Gulf of California at Coatzacoalcos and the Pacific Ocean at Salina Cruz, with a length of 1485 m.

The Mexican government is taking steps to construct a railway of more than 1000 m. across the Gulf of California, from the coast of Sonora to the coast of Veracruz, and it is expected that this project will be completed within a few years.

The Mexican government has also decided to construct a railway from Mazatlan to the Pacific Ocean, which will be about 300 m. in length. This railway is expected to be completed within the next five years.

The Mexican government is also planning to construct a railway from the Gulf of California to the Pacific Ocean, which will be about 400 m. in length. This railway is expected to be completed within the next ten years.

The Mexican government is also planning to construct a railway from the Gulf of California to the Pacific Ocean, which will be about 500 m. in length. This railway is expected to be completed within the next fifteen years.
cotton, woolen and linen textiles and yarns for national factories, hardware, furniture, building material, mining supplies, drugs and chemicals, wines and spirits, wheat, Indian corn, paper and military supplies. The cultivation of coffee, banana, sisal, ixtle and other fibers, cabinet woods, chicle, rubber and other forest products, hides and skins, chickepas, tobacco and sugar.

Although the agricultural resources of Mexico are large and unusually varied, as they comprise some of the cereals and other food products of the temperate zone, and most of the leading products of the tropics. Agriculture, however, received slight attention until the last thirty years. An indirect result of the industrial development of Mexico, which began during the last quarter of the 19th century, has been an increased interest in agriculture. There has been a large investment of capital, such as coffee, sugar and rubber plantations. A large part of the country is too arid for agriculture, and even with irrigation the water supply is sufficient for only a small part of the plateau, and for the same reason, a staple food with the poorer classes, the deficiency is made up through imports. This drawback tends to restrict agriculture on the plateau to comparatively limited areas, and the country people are, in consequence, comparatively small. A new product in this region is that of canaige, which is grown for the tannin found in its root. It is a native of the arid regions and is now cultivated for its large and delicious roots. Coahuila, produces grapes, which are principally used in the manufacture of wine and brandy. An important product of the plateau and of the open districts of the tierras calientes, growing in the most arid places, is the "nopali" or prickly pear cactus (Opuntia ficus indica). Its fruit, called "tuna" by the natives, is refreshing and wholesome and is a staple food of its spiny covering. In the interior of the country, particularly where the soils are more available, the tobacco, indigo, cacao, rice, sweet potatoes, alfalfa, beans and cassava are produced, and Indian corn yields two and three crops a year. Fruits also are plentiful, both wild and cultivated. Among them are the widely grown plantain, tuna, chili pepper, olive, coco-nut, orange, lemon, mango, pomegranate, "piña" or "pineapple" (wild and cultivated), fig, ahuacatl (Persea gratissima), chirimoya (Annona chirimilla), papaya, gourd, melon, guava, ciruela (plum), and the several "zapote" fruits, including "chico zapote" from the Achras sapota, which produces the "chicle" or "chicle-gum of commerce," "zapote blanco" from the Casimiroa edulis, "zapote bartoli" (or "guaje") from the Chrysophyllum bartolii, "zapote prieto" (or "negro") from the Dipsopyros obscura, and "zapote maneyo." The production of rubber is becoming an important industry, large plantations having been set up with both Hevea and Cochliopelta plants. Mexico is one of the better lands in the sub-tropical belt where coffee of an excellent quality is produced, and where coton is cultivated. Coffee has become an important article of export, but it is not cultivated. The "ixtle" or fibres shipped from Tampico and Chiapas are all obtained from the agaves and yuccas found growing wild.

The natural and forest products of Mexico include the agave and yucca (ixtle) fibers already mentioned; the "ceibon" fibre derived from the silk-cotton tree (Bombax pendantia); rubber and vanilla in the states to the cultivated products; palm oil; castor beans; ginger; chicle, the cultivated products of the gum of the white chicle tree (Achras sapota); logwood and other dye-woods; mahogany, rosewood, ebony, cedar and other valuable woods; "cascabel" or prickly pear; jalap root (Peumus); sarsaparilla (Smilax); nuts and fruits.

Stock-raising dates from the earliest Spanish settlements in Mexico, and received no slight encouragement from the mother country. For the most part in Mexico, the cattle are raised on carloads of forage and hay, and the stock-raising industry and stock-raising of some sort is to be found in every state of the republic, though not always to a great extent. The Spanish conquerors found no domestic animals except the horse, and introduced their own horses, cattle, sheep and swine. From these are descended the herds and flocks of to-day, with no admixture of new blood until toward the end of the 19th century. The horsebreed of the cattle are of Spanish origin, and are usually mixed with the local breed. The horse is chiefly used for saddle purposes and is not reared in large numbers. The mule is more generally used in every part of the country, being harder, more intelligent and better adapted for service as a draft and pack animal. The transport of merchandise and produce was wholly by means of pack animals before the advent of railways, and is still considerably in common use. For this purpose the sure-footed mule is invaluable. In some districts, however, oxen and ox-carts are employed, especially in the southern states, and always in the open, level country. The varying climate of Mexico, and the high altitude, is such that the local breed have not only departed from the original Spanish type, but likewise present strikingly different characteristics among themselves. The cattle are raised on grass, being bred on extensive ranges in a cooler atmosphere, and accustomed to long journeys in search of water and pasture. In the south they are larger and better nourished, owing to the permanent character of the pasture, but are less vigorous because of the heat and insect plagues. In Yucatan the open plains, rich pasture, and comparative freedom from heat, insects, and vampire bats, have been partly favourable to cattle-raising, and the cattle are generally rated among the best in Mexico. Notwithstanding the frequency of long, destructive droughts, cattle-raising is a preferred industry among the landowners of the northern states, and particularly in the beachlands. As these lands have frequently experienced, but the profits of a favourable year are so great that losses seldom deter ranchers from trying again. In the Sierra regions of western Chihuahua and Durango, Nuevo Leon, Coahuila, Agualascalientes, San Luis Potosi, and the plateau states farther south, the rainfall is more abundant and the conditions more favourable. The largest herds are to be found in Chihuahua and Durango. Above 5000 ft., the wild pasture is short, tender, and reproduces itself annually. It is exceptionally nutritious, but it disappears altogether in the dry season because of its short roots. The lowland pasture, from 2000 to 5000 ft., is composed of more vigorous and nutritious, with a growth of an equal value and a more permanent character. The stock-raiser on the border pastures his herds on the uplands during the rainy season, and on the lower pastures during the remainder of the year. New and important industries of sheep raising is largely in the hands of the government. They are commonly of the Spanish merino breed, and suffer in many localities on account of insufficient pasture. Some attention is given to the breeding of the merino sheep, and it is produced for the home market and to meet the demand for skins, but the industry is apparently stationary. The raising of swine, however, is increasing. In the last decade of the 19th century the capital invested in these stock industries was estimated (by Bancroft) to exceed $700,000,000, but an official return of the year 1902 gives aggregate valuation of only $120,523,158 (Mexican), or about $2,052,316. According to this return, which is not strictly trustworthy, there were in the country 5,442,457 swine, 5,955,000 head of cattle, 33,443,000 head of sheep, 4,206,011 goats and 616,139 swine. Two years later home consumption returns noted the slaughter of 958,056 cattle (129,938 in the Federal Territories), 50,601 cows, 992,675 goats, and 63,847 sheep. The last item being larger than the census return of 1902. The greater part is consumed in the country, but there is a considerable export of cattle to the United States, Cuba and Central America, and a considerable trade in hides and skins. A large part of pelts and mules are sent to Central America, but the home demand usually exceeds the supply.

Fishing industry.—There are no fisheries of importance except the pearl fisheries on the eastern coast of Lower California, and the tortoise fisheries on the coasts of Campeche, Yucatan, and some of the states facing the Pacific. The pearl fisheries have been worked since the arrival of the Spaniards, and the method of catching them is as old and as primitive as the methods of the aborigines who found it. They are of the type found in Greece, with the exception that the peas are not frozen after being brought up. The British company under a concession from the government. Mother of pearl or abalone and other shells are also found, and, with sponges, are exported. Fishing for the tortoiseshell turtle gives employment
MEXICO

CONSTITUTION

...to a large number of natives in the season, and considerable quantities of the shell are exported. Other industries of a domestic character include the collection of archil, or Spanish moss, on the western side of the Californian peninsula, hunting herons for their plumes (for the manufacture of very expensive feathers for the wild honey), and the gathering of cochineal and ni-in insects. The cochineal insect was once an important commercial product, but the industry has fallen into decay.

Mining.—The best-known and most productive of the industries of Mexico is that of mining. It was the chief object of Spanish policy to attract European immigrants to the New World and to establish a European capital during three centuries of Spanish rule. Agricultural and pastoral industries gradually gained footholds here and there, and in the late 18th century were becoming important in the new country. Only in the last half of the 19th century have the mineral industries been developed. Mines of some description are to be found in 57 of the 31 states and territories, and of these great majority yield silver. According to the official records, there were registered in September 1896, 23,191 mining properties, of which nearly five-sixths were described as producing silver, either by itself or in combination with other metals. The properties were classified as follows: 166,519, silver; 24,381, iron; 9,411, lead; 86, sulphur; 52, antimony; 49, zinc; 21, tin; 61, silver; 6, manganese; 6, "sal gema," 5, tourmalines, 1, bismuth and 1, turquoise—these minerals being various combinations of these. The above figures, however, do not include the many mines at that time considered as private property and were not registered under the general mining laws. A comparison with 1846, when 85,237 properties were described, would show that the mining industry is not only expanding rapidly the number of mines have been developed during that period. Besides the above, the mineral resources of Mexico include coal, petroleum, asphalt, platinum, graphite, varnish and asphalt. In 1896 the productive mines numbered 1,786, of which 491 were in Sonora, 282 in Chihuahua, 211 in Durango, 113 in Oaxaca and 105 in Nuevo Leon. Gold is found in Chihuahua, Durango, Guanajuato, Guerro, Jalisco, Mexico, Morelos, Oaxaca, Puebla, Sinaloa, Sonora, Tamaulipas, Tlaxcala and the Yucatan peninsula; copper in Lower California, Guanajuato, Guerrero, Hidalgo, Michoacan and Sonora; Tamaulipas and some other states; mercury chiefly in Guanajuato, Guerro, Su Ljos Potosi, Vera Cruz and Zacatecas; tin in Guanajuato; coal, petroleum and asphalt in 20 states, but chiefly in Coahuila, Hidalgo, Michoacan, Oaxaca, Puebla, Sonora, Tamaulipas and Vera Cruz; iron in Durango, Hidalgo, Oaxaca and other states; and lead in Hidalgo, Querétaro and in many of the silver-producing districts. The most important coal deposit is that of the Cerro del Mercado, in the outskirts of the city of Durango—a mountain 640 ft. in height, 1100 in breadth and 4800 in length reputed to be almost a solid mass of iron. Large masses of the metal are found also in the Sierra Madre, the principal coalfields that have been developed are in the vicinity of Salinas, Coahuila. They have been opened up by American capital, and are not used on the railroads passing through that region. Mexican coal is of a low grade, similar to that found in Texas, but as an official geological report of 1905 estimates the supply in sight at 200,000,000 tons its industrial value to the country cannot be computed in dollars, as the coal on this coast is used for the refining purposes, they furnish an excellent fuel for railway engines and other industrial purposes. Many of the Mexican railroads and industrial furnaces use coal, which are produced in sufficient quantities for local requirements. In 1909 a well was opened in the southern oilfields whose yield was equal to the best American product.

Manufactures.—Although Mexico is usually described as a non-manufacturing country, the government under President Porfirio Díaz will warrant some modification of this characterization. Manufacturing for international trade has not been and may never be important except for the great woolen products of which there are large exports, and that of the manufacture of cigarettes, which is one of the principal foreign trade of the country. There were of course some crude industries in existence before the arrival of the Spaniards, and such industries as the manufacture of casimere, hats, leather, cloth and soaps, which are still in existence. The early methods of making cane sugar, clarified with chicle from the gum, and natural honey, were in conical moulds, are to be found all over Mexico, and the annual output of this brown or muscovado sugar called "panees" by the native Mexicans was estimated at 90,947,5 metric tons. In recent years this has been considerably increased, and the annual output was estimated at 180,000 tons in 1905. The chief form of sugar is panela, which is made by boiling the molasses, which is then cast into moulds, where it is cooled and then broken up. In 1905 the output of molasses was reported 123,285 metric tons, in addition to which the molasses output was estimated at 70,947.5 metric tons, and "panelas" at 50,000 tons. Other estimates make the "panelas" output much larger, the product being largely consumed in the rural districts and never appearing in the larger markets. The estimated number of sugar mills in 1904 was about 2000, of which only about 300 were the principal concern for the manufacture of muscovado sugar. It was introduced in 1541 and woolen manufactures date from that time. Large factories are now to be found in all parts of Mexico, and good and serviceable grades of broadcloths, cassimares, blankets and other fine fabrics are manufactured. The Mexican silver mining industry has reached great development, and the production of silver, copper, lead and zinc is one of the most important industries of the country. In 1888-1889, 91,000 tons of silver was produced, and 1,105,000 tons of silver in 1905, of which 95,212,000 tons were produced in Mexico, and the balance imported from foreign countries. The silver was produced in 160 factories in 1905, of which 19 were idle, and these were distributed over a very large part of the country. About one-half the raw cotton consumed was produced in Mexico, and the balance imported in fibre or yarn. The industry is protected by a high tariff, and the production of raw cotton, and further encouragement is offered through a remission of internal revenue taxes where Mexican fabrics are exported. The cotton factories of 1905 were supplied with 22,021 looms having 678,938 spindles, and with 38 stamping machines, employed 30,162 operatives, and turned out 1,173,653,805 pieces of cloth. Statistical returns, however, are sometimes incomplete, and the census figures are sometimes exclusive of textile establishments. Another important manufacturing industry is now developing the textile products of many among all classes of products. Many of the European countries are now establishing factories in Mexico, and it is estimated that by 1910 the country will be engaged in the manufacture of cotton, chintzes, cigarettes, snuff and cut tobacco for the pipe. The number of factories reported for 1899 was 735, but as the consumption of leaf tobacco increased from 5,400,000 to 8,500,000 kilogrammes, it may be assumed that the decrease in factories is due to the absorption or disappearance of the small shops using old-fashioned methods. Other important manufactories are flour mills, of which there were 72 in 1895. They have been improved greatly, and have brought into the country large numbers of skilled operatives, especially in the cotton, iron and steel, and smelting industries.

Constitution.—Under the Constitution of the 5th of February 1857, subsequently modified in many important particulars, the government of Mexico is described as a federation of free and sovereign states invested with representative and democratic institutions. Practically it is a Federal Republic with centralized executive powers. Its political divisions consist of 27 states and 3 federal districts; 87,615 city, town and village governments, and have brought into the country large numbers of skilled operatives, especially in the cotton, iron and steel, and smelting industries.
citizen in the full exercise of his political rights, 35 years of age, not an ecclesiastic, and a resident of the republic at the time of the election. Although the authority of the president is carefully defined and limited by the Constitution, the exercise of dictatorial powers has been so common that the executive may be considered practically supreme and irresponsible. Previous to the presidency of General Porfirio Díaz in 1877 political disorders and changes in government were frequent.

The legislative branch of government consists of a Congress of two chambers—a senate and a chamber of deputies. Two ordinary congressional sessions are held each year, April 1 to July 1 and September 16 to December 15—and a permanent committee of 20 members (14 senators and 6 deputies) sits during recess, with the power to confirm executive appointments, to give assent to a mobilization of the national guard, to convene extra legislative sessions, to administer oaths, and to report at the next session on matters requiring congressional action. The senate is composed of 56 members—or two from each state and from the federal district—who are elected by popular vote for a term of four years, one-half the number retiring every two years. A senator must be not under 35 years of age, a naturalized citizen, and have been a resident of the state he represents, and not an ecclesiastic. The chamber of deputies is composed of popular representatives, in the proportion of one deputy for each 40,000 inhabitants or a fraction over 20,000, who are elected for a term of two years. A deputy must be not less than 25 years of age, other qualifications being the same as those for a senator. The salary for either senator or deputy is $3,000 and that of the president $50,000. Federal officials and ecclesiastics are ineligible for election to either chamber.

Mexican citizenship includes all persons born of Mexican parents, all naturalized aliens, and all foreigners owning real estate in the republic or having children by Mexican mothers unless formal declaration is made of an intention to retain the citizenship of another country. In some cases exemptions are granted from specified taxes and military duties, otherwise naturalized citizens are treated the same as native-born. Aliens are granted the civil rights enjoyed by Mexicans, but the government reserves the right to expel those guilty of pernicious conduct. Suffrage is extended to all Mexican citizens who possess honest means of livelihood, the age limit being 18 for the majority and 21 for the unmarried. A woman who has lived with a man for a year and a partidas, distritos, &c. are governed by a jefe politico, or prefect, and the smaller by a municipal council called an ayuntamiento.

Defence.—The Mexican army consists of 2,474 officers and 24,132 men, organized on modern lines, and commanded by a general staff at the capital. There were 30 battalions of infantry stationed at garrisons and 10 regiments of cavalry, 16 regiments of artillery, 50 battalions of infantry, and 14,899 men; 2 regiments and 3 cadres of field artillery; 2 regiments of horse and mountain artillery, 4 sections of garrison artillery, an artilleria de campaña, in all 147 officers and 1,047 men; and the remainder divided among other services. Administration and headquarters staffs are also provided. The Mexican army has its own workshops and armories, and is not dependent for cannon, rifles, and other arms, on foreign manufacturers."

The nominal strength of the army is rated at 2,510 officers and 81,934 men. Factories for arms and ammunition have been established with modern machinery, and uniforms and other equipment are made in the country. The military school in the capital occupies a part of the historic castle of Chapultepec and has been thoroughly reorganized on modern lines. There is also an artillery school at Vera Cruz and subordinate schools in other parts of the republic. The national guard, to which reference is sometimes made, has no effective organization.

Its officers and men consider it a civil guard, its navy, the ten small vessels in commission in 1908 hardly meriting such a designation; old dispatch boats and 2 old unarmoured gunboats, a steel training cruiser, the "Zaragoza," and 5 small modern gunboats. The personnel of 1904 exceeded 106,785 men, but the majority of them were unarmour'd; 34,555 officers and men were under arms, but only 7,806 were projected, but the republic has no pressing need of a navy. Small naval schools are maintained at Campeche and Mazatlán.

Education.—Education in Mexico may be said to have entered upon a progressive phase only in the late 19th century. The old state cadres were wholly under ecclesiastical control. The first college in Mexico was founded during the administration of Viceroy Mendoza (1535–1541) but it taught only the Latin, rhetoric, grammar, and theology. The university of Mexico, planned by Mendoza and founded on the 21st of September 1551, was formally opened on the 25th of January 1553, with faculties of law, philosophy and theology, and 20 students. Mexico was not in a position to give instruction in the catechism. The university of Mexico received much support from both church and state, but it never gained a position comparable to the universities of South America—Cordoba, Lima (San Marcos) and the like. The overthrow of Spanish rule in Mexico was the beginning of a new period, and efforts were made to introduce educational reforms, but the colonists and ecclesiastics were still governed by their fears and prejudices, and little was accomplished. In 1833 the university of Mexico suspended work, and in 1865 passed out of existence altogether. In 1857 the adoption of a more liberal and democratic constitution paved the way for educational reforms. In the education of the clergy the question of instruction was delayed by the wars that devastated the country down to the overthrow of Maximilian, but the leaven was at work, and with the return of peace a marked increase in the number of schools was noted. The education of the masses was neglected, and the sciences and engineering were created in Mexico City in 1865 in place of the old university and were successful from the beginning. By the reforms established in 1866 the government took control of all important provincial capitals, and everywhere increasing interest in educational matters was apparent. The best proof of this was to be found in the development of the primary schools, of which there were 22,266 in 1874, with an attendance of 600,000 pupils. Of these, 603 were supported by the national government, 3,240 by municipalities, 2,260 by private enterprise, 117 by the Catholic church, and the remainder by Protestant denominations. Handsome schools were established in the cities and large towns, and schools were opened in all the villages and hamlets. In some parts the natives made creditable progress in all branches of learning. This was especially true of the state of Oaxaca and the district of Tonalá in the east, the leading men of the republic. The national school laws now in force had their origin in the recommendations made by a national congress of public education convened on the 1st of December 1875, and a law of 1876 established "field schools" as the result was a law regulating free and compulsory education in the federal district and national territories, which came into effect on the 17th of January 1892. From 1822 to this time the education of public schools had been under the control of the Compañía Lancastriana, but they were now placed under charge of the Department of Public Education. On the 19th of May 1866 a general public education law was promulgated and also schools were established for the public schools, and outlined a comprehensive system. Compulsory attendance had been adopted in 1885, but did not come into effect until after the enactment of the law of 1902. For uniform instruction, and compulsory attendance for children of 6 to 12 years of age. Preparatory courses for professional training in the government schools were also made free and secular. As the
MEXICO

[RELIGION: FINANCE]

states have control of the schools within their own boundaries that there is a great lack of uniformity, but the national system is being generally adopted. In the official report for 1904 the number of public schools, exclusive of infant schools, was returned at 9,101 (against 5,534 in 1894), of which 9,000 were supported by the national and state governments and 276 by the municipalities. The private, religious and association schools numbered 2,331, with 55,838 pupils. For secondary instruction there are 3 federal and state grammar schools, 69 for boys, and for professional instruction 65 with 9,018 students, of whom 3,700 were women. Normal schools for the training of teachers are also maintained at public expense and are giving good results. But for the most part, the government maintains schools of agriculture and veterinary practice, engineering, mining, commerce and administration, music and fine arts. There is also a mechanics' technical school (arist y oficio) for men and a similar school for women, schools for the blind and for deaf-mutes, reform schools, and garrison schools for soldiers. Early estimates were that 90% of the population were illiterate. In 1895 this percentage was reduced to about 52% and the work of the schools is daily cutting it. Mention must be made of the National Library in Mexico City with about 225,000 volumes, and 138 public libraries (in 1904) in other parts of the republic. 34 museums for scientific, educational and art purposes, and 11 meteorological observatories. Newspapers and periodicals, whose educational value varies widely, numbered 409 in 1904, of which 349 were in Spanish and 12 in English. The people are predominantly of the Roman Catholic faith; the census of 1900 returning 13,533,013 communicants in of that church, $1,795 Protetants (in great part foreigners), 381 of other faiths, and 1,860,000 of no faith. The Roman Catholicism is tolerated to all religions, and since 1868 several Protestant denominations have established missions in the towns, but their numbers are still comparatively small. The Roman Catholic Church was enriched by the conquerors of the conquest, whose stipends and patrones may still be considered semi-pagan, the gods of their ancestors being worshipped in secret, and the tenets and dogmas of the faith but faintly comprehended, being largely adulterated with superstitions and practices of pagan origin. The church hierarchy consists of 3 archbishops and 23 suffragans bishops. It dates from the creation of the bishopric of Mexico in 1530, with Fermin de Zunzamara as bishop, the other two previous bishops of whom had been proclaimed at Rome, that of Yuatcan in 1518 and Puebla in 1525. In 1545 the bishopric of Mexico was elevated to an archbishopric, which was divided into three archdioceses, Mexico, Michoacan and Guadalajara. An Inquisition tribunal was established in the capital in 1571, and in 1574 its first auto-da-fe was celebrated with the burning of "twenty-one pestilent Lutherans." The Inquisition was active in Mexico during two and a half centuries, and was finally suppressed on the 31st of May 1820. The great power exercised by the Roman Catholic Church during the colonial period enabled it not only to mould the spiritual belief of the whole people, but also to control their education, tax their industry, and control the political policies governing their daily life. In this way it acquired great wealth, becoming the owner of extensive estates in every part of the country and of large productive properties and towns. It was said in 1899 that the church owned one-third of the real and personal property of the republic. The reform laws of that year nationalized its property, abolished its numerous orders and mendicant friaries and deprived it of state support and of participation in political affairs. Subsequent legislation removed clerical influence from public instruction, made marriage a civil ceremony and closed all conventual establishments. The church still exercises a boundless influence over the Mexican lower classes, and is still the most influential organization in the republic.

Finance.—The national revenues are derived from import and export duties, port dues and other taxes levied on foreign commerce, and excise and stamp taxes and other charges upon internal business transactions; from direct taxes levied in the federal district and national territories, comprising a land tax in rural districts, a house tax in the city, commercial and professional licences, rents, and sundry taxes on bread, publicans, vehicles, saloons, theatres, &c.; from postigate duties and registry fees; from a surcharge on all taxes levied in the Mexican state, which is called the "estadu," which is paid in federal revenue stamps; from post and telegraph receipts; from post and telegraphic receipts and from some minor sources of income. The most fruitful revenue is the salt tax, which is estimated to yield 50% of the total receipts. The excise taxes in 1905 were levied on tobacco, alcohol and alcoholic beverages, and on cotton goods. Mining taxes, which are very low, and taxes on the value of minerals, are also small. An initial tax of 14% is levied on the claim (pertenencia), an annual or rental tax on each claim, and a tax of 3% (1908) on the export of unrefined gold and silver, 2% on ingot ores, and 1% on pure silver. The expenditures are chiefly for the service of the public debt, public works, and salaries (Department of the Interior). The public debt service alone required $25,201,573 (5,620,187) in 1908.

For the fiscal year 1906-1907 the revenue produced a total of $1,428,122 pesos (dollars), or, approximately, $1,428,612, and the expenditure was $8,076,641 pesos, or $8,076,667. The estimates for 1908-1909 show a marked decline owing to the commercial depression, the revenue being computed at 103,385,800 pesos, and the expenditure at 103,383,800 pesos. Of the former 46,900,000 pesos are credited to import duties, 31,900,000 pesos to stamps, excises, and licences, and other direct taxes are reduced from 9 to various sources. Owing to the circumstance that the great majority of the Mexican people own no property, carry on no industry, and are not even to be considered regular productive farmers, their resources are small in relation to the population and are comparatively indefinite.

The revenues and expenditures of the states and municipalities in 1904, the latest date available, aggregated as follows:

<table>
<thead>
<tr>
<th>States</th>
<th>Revenue</th>
<th>Expenditure</th>
</tr>
</thead>
<tbody>
<tr>

<td>24,519,926 pesos</td>
<td>23,557,698 pesos</td>
</tr>
</tbody>
</table>

The taxes cover a great variety of occupations and property, often to a minute and varying degree, and be no cost of the expenses of local administration, schools, police, streets and other objects of purely local interest.

The public indebtedness of Mexico includes a foreign debt payable in gold, an internal debt payable in silver, and a floating debt covering unpaid balances on appropriations, unpaid interest, and other credits and obligations. The paper money issues are by banks and not by the government, and the national banks keep no cash in its vaults and has no sinking funds to offset this indebtedness.

The foreign debt dates from 1825, when $10,000,000 were borrowed in London through two loans. Interest defaults led to a conversion of the loan at a disadvantage in 1858 and another in 1868. Further defaults followed and in 1888 another adjustment was made by the issue of 6% gold-bearing bonds. From this time the Mexican government has met its obligations promptly, in consequence of the large per cent is rated high and its bonds have been quoted at a premium. In 1896 the government placed a loan of $22,750,000 in Europe at 5% for the conversion of its 6% bonds, and in 1902 to another $5,000,000. In 1904 the Mexican government has met its obligations promptly, in consequence of the large per cent is rated high and its bonds have been quoted at a premium. In 1896 the government placed a loan of $22,750,000 in Europe at 5% for the conversion of its 6% bonds, and in 1902 to another $5,000,000. In 1904 the Mexican government has met its obligations promptly, in consequence of the large per cent is rated high and its bonds have been quoted at a premium. In 1896 the government placed a loan of $22,750,000 in Europe at 5% for the conversion of its 6% bonds, and in 1902 to another $5,000,000. Previous to 1905 all monetary transactions in Mexico were based in practice on a circulating silver standard and free coinage. By a law of the 9th of December, 1894, precisely one century after the fiat decree of the 25th of March 1895, the gold standard was adopted, and the silver peso, 9027 fine and containing 24.3538 grams of pure silver, was made the monetary unit with a valuation of 75 grams of pure gold. At the same time the free coinage of silver was suspended, the government reserving to itself the sole privilege of making money. The coinage of Mexico, now concentrated at the mint in Mexico city, has been defined and is being (since November 28, 1867) on the decimal system—the peso being divided into 100 centavos—and consists of gold, silver, nickel and bronze coins, whose weight and fineness are determined by the monetary law of 1904. The coins minted under this law are:

MEXICO

(A. J. L.)

HISTORY

I.—Ancient Mexico.

The name Mexico is connected with the name of the group of American tribes calling themselves Mexico (sing. Mexicoll) or Azteca. The word is related to or derived from the name of the Mexican national war-god, Mextitl, better known as Huiztilpochtil. The Aztecs from the 12th century have appeared to have migrated from place to place over the mountain-walled plateau of Anauacue, the country "by the water," so called from its salt lagoons, which is now known as the Valley of Mexico. About 1325 they founded on the lake of Texcoco the permanent settlement of Mexico Tenochtitlan, which is still represented by the capital city, Mexico. The name Mexico 1 was given by the Spanish conquerors to the group of countries over which the Aztec power more or less prevailed at the time of the European invasion. Clavigero (Storia antica del Messico, vol. i.) gives a map of the so-called "Mexican empire," which may be roughly described as reaching from the present Zacatecas to beyond Guatemala; it is noticeable that both these names are of Mexican origin, derived respectively from words for "straw" and "land." Eventually Mexico and New Mexico came to designate the still vaster region of Spanish North America, which (till cut down by changes which have limited the modern republic of Mexico) reached as far as the Isthmus of Panama on the south and took in California and Texas on the north.

Mexico in this wide sense is of high interest to the anthropologist from the several native American civilizations which appear within its limits, and which conveniently if loosely group themselves round two centres, the Mexican proper and the Central American.

When early in the 16th century the Spaniards found their way from the West India Islands to this part of the mainland of America, they discovered not rude and simple tribes like the islanders of the Antilles, but nations with armies, official administrators, courts of justice, high agriculture and mechanical arts, and, what struck the white men especially, stone buildings whose architecture and sculpture were often of dimensions and elaborateness to astonish the builders and sculptors of Europe. Here was a problem which excited the liveliest curiosity and gave rise to a whole literature. Hernandez and Acosta shared the opinion of their time that the great fossil bones found in Mexico were remains of giants, and that, as before the deluge these giants on the earth, therefore Mexico was peopled from the Old World in antediluvian times. On the other hand the multitude of native American languages suggested that the migration to America took place after the building of the tower of Babel, and Siguenza arrived at the curiously definite result that the Mexicans were descended from Naphthun, son of Mizraim and grandson of Noah, who left Egypt for Mexico shortly after the confusion of tongues. Although such speculations have fallen out of date, they induced the collection of native traditions and invaluable records of races, languages and customs, and have bettered Mexico in the 19th century Lord Kingsborough spent a fortune in printing a magnificent compilation of Mexican picture-writings and documents in his Antiquities of Mexico to prove the theory advocated by Garcia a century earlier, that the Mexicans were the lost tribes of Israel. Modern archaeologists approach the question from a different standpoint, but the origin of the American aborigines and of Mexican civilization remains extremely obscure (see America, where the primitive Mexican cultures are fully illustrated, and Central America).

Real information as to the nations of Mexico before Spanish

1 In this, as in all other Aztec names, the x (or $) represents the English sound sh; hence Mexicoll and Mexico should be properly pronounced Meschillt, Meschico. But they do not appear to have ever been so pronounced by the Spaniards, who naturally gave to the x its ordinary Spanish sound of the German ch.
times is very imperfect, but not altogether wanting. The accurate and experienced Alexander von Humboldt considered the native American races of both continents to be substantially similar in race-characters. Such a generalization will become sounder, if, as is now generally done by anthropologists, the Eskimo with their pyramidal skulls, dull complexion and flat noses are removed into a division by themselves. Apart from these polar nomads, the American indigens group roughly into a single division of mankind, of course with local variations. If our attention is turned to the natives of Mexico especially, the unity of type will be found particularly close. The native population of the plateau of Mexico, mainly Aztecs, may still be reckoned by thousands without any trace of mixture of European blood. Their stature is estimated to be about 5 ft. 3 in., but they are of muscular and sturdy build. Measurements of their skulls show them mesocephalic (index about 78), or intermediate between the dolichocephalic and brachycephalic types of mankind. The face is oval, with low forehead, high cheek-bones, long eyes sloping outward towards the temples, bushy lips, nose wide and in some cases flattish but in others aquiline, coarsely moulded features, with a stolid and gloomy expression. Thickness of skin, masking the muscles, has been thought the cause of a peculiar heaviness in the outlines of body and face; the complexion varies from yellow-brown to chocolate (about 40 to 43 in the anthropological scale); eyes black; straight glossy black hair; beard and moustache scanty. Among variations from this type may be mentioned higher stature in some districts, and lighter complexion in Tehuantepec and elsewhere. If now the native Americans be compared with the races of the region across the oceans to their east and west, it will be seen that their unlikeliness is extreme to the races eastward of them, whether white Europeans or black Africans. On the other hand they are considerably like the Mongoid peoples of north and east Asia (less so to the Polynesians); so that the general tendency among anthropologists has been to admit a common origin, however remote, between the tribes of Tartary and of America. This original connexion, if it may be accepted, would seem to belong to a long-past period, to judge from the failure of all attempts to discover an affinity between the languages of America and Asia. At whatever date the Americans began to peoples America, they must have had time to import or develop the numerous families of languages actually found there, in none of which has community of origin been satisfactorily proved with any other language-group at home or abroad. In Mexico itself the languages of the Nahua nations, of which the Aztec is the best-known dialect, show no connexion of origin with the language of the Otomi tribes, nor either of these with the languages of the regions of the ruined cities of Central America, the Quiché of Guatemala and the Maya of Yucatan. The remarkable phenomenon of nations so similar in bodily make but so distinct in language can hardly be met except by supposing a long period to have elapsed since the country was first inhabited by the ancestors of peoples whose language has since passed into so different forms. The original peopling of America might then well date from the time when there was continuous land between it and Asia.

It would not follow, however, that between these remote ages and the time of Columbus no fresh immigrants can have reached America. We may put out of the question the Scandinavian sea-rovers who sailed to Greenland about the 10th century and at all times communication has been open from east Asia, and even the South Sea Islands, to the west coast of America. The importance of this is evident when we consider that late in the 19th century Japanese junkins still drifted over by the ocean current to California at the rate of about one a year, often with some of the crew still alive. Further north, the Aleutian islands offer a line of easy sea passage, while in north-east Asia, near Bering's Straits, live Chukchi tribes who carry on intercourse with the American side. Moreover there are determined Mexican civilization which are most easily accounted for on the supposition that they were borrowed from Asia. They do not seem ancient enough to have to do with a remote Asiatic origin of the nations of America, but rather to be results of comparatively modern intercourse between Asia and America. Humboldt (Vues des Cordillères, Pl. xxi.) compared the Mexican calendar with that in use in eastern Asia. The Mongols, Tibetans, Chinese and other neighbouring nations have a cycle or series of twelve animals, viz. rat, bull, tiger, hare, dragon, serpent, horse, goat, ape, cock, dog, pig, which may possibly be an imitation of the ordinary Babylonian-Greek zodiac familiar to our ancestors. The Mongolian peoples not only count their lunar months by these signs, but they reckon the successive days by them, rat-day, bull-day, tiger-day, &c., and also, by combining the twelve signs in rotation with the elements, they obtain a means of marking each year in the sixty-year cycle, as the wood-rat year, the fire-tiger year, &c. This method is highly artificial, and the reappearance of its principle in the Mexican and Central American calendar is suggestive of importation from Asia. Humboldt also discussed the Mexican doctrine of four ages of the world belonging to water, earth, air and fire, and ending respectively by plague, earthquake, tempest and conflagration. The resemblance of this to some versions of the Hindu doctrine of the four ages or yuga is hardly to be accounted for except on the hypothesis that the Mexican theology contains ideas learnt from Asiatics. Among Asiatic points of resemblance to which attention has since been called is the Mexican belief in the nine stages of heaven and hell, an idea which nothing in nature would suggest directly to a barbaric people, but which corresponds to the idea of successive heavens and hells among Brahmins and Buddhists, who apparently learnt it (in considerably modified form) from the Hindus. The Mexican doctrine of successive stages or concentric planetary spheres belonging to the planets, &c. The Spanish chronicles also give accounts of a Mexican game called patolli, played at the time of the conquest with coloured stones moved on the squares of a cross-shaped figure, according to the throws of beans marked on one side; the descriptions of this rather complicated game correspond closely with the Hindu backgammon called pachisi (see Tylor in Journ. Anthropol. Inst., viii. 110).

The native history of Mexico and Central America is entitled to more respect than the scattered recollections of savage tribes. The Mexican pictures so far approached writing proper as to set down legibly the names of persons and places and the dates of events, and at least helped the professional historians to remember the traditions repeated orally from generation to generation. Thus actual documents of native Aztec history, or copies of them, are still open to the study of scholars, while after the conquest interpretations of these were drawn up in writing by Spanish-educated Mexicans, and histories founded on them with the aid of traditional memory were written by Ixtlilxochitl and Tezozomoc. In Central America the rows of complex hieroglyphs sculptured on the ruined temples probably served a similar purpose. The documents written by natives in later times thus more or less represent real records of the past, but the task of separating myth from history is of the utmost difficulty. Among the most curious documents of early America is the Popol-Vuh or national book of the Quiché kingdom of Guatemala, a compilation of traditions written down by native scribes, found and translated by Father Ximenes about 1550, and published by Scherzer (Vienna, 1857) and Brasseur de Bourbourg (Paris, 1861). This book begins with the time when there was still a sea between the continents, and the wind, but as yet there was no body, nothing that clung to anything else, nothing that balanced itself or rubbed together or made a sound; there was sought below but the calm sea alone in the silent darkness. Alone were the Creator, the Former, the Ruler, the Feathered Serpent, who they give being and whose name is Gucumatz. Then follows the creation, when the creators said "Earth," and the earth was formed like a cloud or a fog, and the mountains appeared like lobsters from the water, cypress and pine covered the hills and valleys, and their forests were peopled with beasts and birds, but the only place where the name of their creator, but could only chatter and croak. So man was made first of clay, but he was strengthless and senseless
MEXICO

and melted in the water; then they made a race of wooden mannikins, but these were useless creatures without heart or mind, and they were destroyed by a great flood and pitch poured down on them from heaven, those who were left of them being turned into the apes still to be seen in the woods. After this comes the creation of man, and then the division of the ancestors of the Quichés, and the tradition records the migrations of the nation to Tulan, otherwise called the Seven Caves, and thence across the sea, whose waters were divided for their passage. It is worth while to mention these few early incidents of the national legend of Guatemala, because their Biblical incidents show how native tradition incorporated matter learnt from the white men. Moreover, this Central American document, mythical as it is, has an historical importance from its bringing in names belonging also to the traditions of Mexico proper. Thus Gucumatz, "Feathered Serpent," corresponds in time to the Mexican deity Quetzalcoatl; Tulan and the Seven Caves are familiar words in the Aztec migration traditions, and there is even mention of a chief of Toltec, a name plainly referring to the famed Toltecs. Thus the legends of the Popol-Vuh confirm what is learnt from comparing the culture of Central America and Mexico proper, that, though these districts were not connected by language, the intercourse between them had been sufficient to justify the anthropologist in including both districts in one region. Historical value of the ordinary kind may be found in the latter part of the Popol-Vuh, which gives names of chief of the tribes when they began to bear Spanish names, and the great city of Quiché became the deserted ruin of Santa Cruz. The Maya district of Yucatan has also some vestiges of native traditions in the manuscript translated by D. Pio Perez (in Stephens, Incidents of Travel in Yucatan) and in the remarkable 16th century Relacion de las cosas de Yucatan by Diego de Landa, published by Brassey de Bourbourg (Paris, 1864). As in the Guatemala traditions, we hear of ancient migration from the Mexican legendary region of Tula; and here the leaders are four famous chiefs or ancestors who bear the Aztec name of the Tutul-Xiu, which means "Bird Tree." Unfortunately for the historical standing of these four ancestors, there are in the Aztec picture-writing representations of four trees, each with a bird perched on it, and placed facing the four quarters, which make it probable that the four Tutul-Xiu of tradition may be only mythic personifications of the four cardinal points (see Schultze-Sellack in Zeitschr. f. Ethn., 1879, p. 209). Nevertheless, part of the later Maya records may be genuine—for instance, when they relate the war about three centuries before the Spanish conquest, when the king of Chichen-Itza destroyed the great city of Maya-pan. Though the Central American native kings have too little importance of the tribes to be dwelt on here, they bring into view one important historical point—that the ruined cities of this region are not monuments of a forgotten past, but that at least some of them belong to history, having been inhabited up to the conquest, apparently by the very nations who built them.

Turning now to the native chronicles of the Mexican nations, these are records going back to the 12th or 13th century, with some vague but not worthless recollections of national events from times some centuries earlier. These traditions, in some matters, seem to have been altered by the Hispanic conquerors, and in others, by the immigration of detachments of a widespread race speaking a common language, which is represented by the Aztec, still a spoken language in Mexico. This language was called nahuatl, and one who spoke it as his native tongue was called nahuaulteoi, so that modern anthropologists are following native precedent when they use the term Nahua for the whole series of peoples now under consideration. Earliest of the Nahua nations, the Toltecs are traditionally related to have left their northern home of Huehueteypadlan in the 6th century; and there is other evidence of the real existence of the nation. Their name Toltecal signifies an inhabitant of Tula (land of reeds), a place which has a definite geographical site in the present Tula or Tula, north of the valley of Anahuac, where a Toltec kingdom seems to have had its centre. To this nation was due the introduction of maize and cotton into Mexico, the skilful workmanship in gold and silver, the art of building on a scale of vastness still witnessed to by the mound of Chohula, said to be Toltec work, and the Mexican hieroglyphic writing and calendar. With the Toltecs is associated the tradition of Quetzalcoatl, a name which presents itself in Mexican religion as that of a great deity, god of the air, rising into the heavens as that of a bearded, feathered, and beardless worshipper who is mistaken for another race, a white man with noble features, long black hair and full beard, dressed in flowing robes. He came from Tulan or from Yucatan (for the stories differ widely), and dwelt twenty years among them, teaching men to follow his austere and virtuous life, to hate all violence and war, to sacrifice no men or beasts on the altars, but to give mild offerings of bread and flowers and perfumes, and to do penance by the votaries drawing blood with thorns from their own bodies. Legend tells stories of his teaching men picture-writing and the calendar, and also the artistic work of the silversmith, for which Chohula was long famed; but at last he departed, some say towards the unknown land of Tlapallan, but others to Coatzacoalcos on the Atlantic coast on the confines of Central America, where native tradition still keeps up the divine names of Gucumatz among the Quiches and Cukulcan among the Mayas, these names have the same meaning as Quetzalcoatl in Aztec, viz. "Feathered Serpent." Native tradition held that when Quetzalcoatl reached the Atlantic he sent back his companions to tell the Cholulas that in a future age his brethren, white men and bearded like himself, should land in the sea where the sun rises and come to rule the country. That there is a basis of reality in the Toltec traditions is shown by the word toltecacl having become among the later Aztecs a substantive signifying an artist or skilled craftsman. It is further related by the Mexican historians that the Toltec nation all but perished in the 11th century by years of drought, famine and pestilence, a few only of the survivors remaining in the land, while the rest migrated into Yucatan and Guatemala. After the Toltecs came the Chichimecs, whose name, derived from chic, dog, is applied to many rude tribes; they are said to have come from Amaquemecan under a king named Xolotl, names which being Aztec imply that the nation was Nahua; at any rate they appear afterwards as fusing with more cultured Nahua nations in the neighbourhood of Tezcucu. Lastly is recorded the Mexican immigration of the seven nations, Xochimilca, Chalca, Tepaneca, Acolhua, Tlahuica, Tlascalteca, Azteca. This classification of the Nahuaatlc tribes has a meaning and value. It is true that Aztlan, the land whence the Aztecs traced their name and source, cannot be identified, but the later stages of the long Aztec migration seem historical, and the map of Mexico shows that it is quite consistent with the famous migration map, published by Gemelli Careri (Giro del mondo, Venice, 1728) and commented on by Humboldt; among these local names are Tzompanco, "place of skulls," now Zumpango in the north of the Mexican valley, and Chapultepec, "grasshopper hill," now a suburb of the city of Mexico itself, where the Aztecs are recorded to have celebrated in 1195 the festival of tying up the "bundle of years" and beginning a new cycle.

The Aztecs moving from place to place in Nahua were little known forms of Nahua peoples already settled there. One of the first clear events of the Aztec arrival is their being made tributary by the Tepanees, in whose service they showed their warlike prowess in the fight near Tepycayacu, where now stands the famous shrine of Our Lady of Guadalupe. Thus they overcame the Acolhous, who had made Tezcucu a centre of prosperity. By the 13th century the Aztecs by their ferocity had banded their neighbours together against them; some were driven to take refuge on the reedy lake shore at Acoyuluco, while others were taken as captives into Culhuaucan. The king of this district was Coxcoxtli, whose name has gained an undeserved reputation even in Europe, as "Coxcoxtli, the Mexican Noah," from a scene in the native picture-writing where his name appears together with the figure of a man floating in a dug-out tree, which has been mistaken even by Humboldt for a representation of the
Mexican deluge-myth. Coxcoxtli used the help of the Aztecs against the Xochimilco people; but his own nation, horrified at their bloodthirsty sacrifice of prisoners, drove them out to the islands and swamps of the great salt lagoon, where they are said to have taken to making their chinampas or floating gardens of mud heaped on rafts of reeds and brush, which in later times were so remarkable a feature of Mexican agriculture. As one of the Aztec warriors at the time of the founding of their city was called Tenoch, it is likely that from him was derived the name Tenochtitlan or "Stone-cactus place." Written as this name is in pictures or rebus, it probably suggested the invention of the well-known legend of a prophecy that the war-god's temple should be built where a prickly pear was found growing on a rock, and perched on it an eagle holding a serpent; this legend is still commemorated on the coins of Mexico. Mexico-Tenochtitlan, founded about 1325, for many years afterwards probably remained a cluster of huts, and the higher civilization of the country was still to be found, especially among the Acolhuas in Tezcuzco. The wars of this nation with the Tepanecs, which went on into the 15th century, were merely destructive, but larger effects arose from the expeditions under the Culhua king Acamapichtli, where the Aztec warriors were prominent, and which extended far outside the valley of Anahuac. Especially a foray southward to Quauhnauac, now Cuernavaca, on the watershed between the Atlantic and Pacific, brought goldsmiths and other craftsmen to Tenochtitlan, which now began to rise in arts, the Aztecs having their rude gardens of flax and hemp, costly clothing, and gold and silver for foreign merchandise. In the 14th century the last great national struggle took place. The Acolhuas had at first the advantage, but Ixtlilxochitl did not follow up the beaten Aztecs but allowed them to make peace, whereupon, under professions of submission, they fell upon and sacked the city of Tezcuzco. The next king of Tezcuzco, Nezahualcoyotl, turned the course of war, when Azcapulco was occupied, the Tepanec stronghold, was taken, and the inhabitants sold as slaves by the conquering Acolhuas and Aztecs; this place thus deserted became the market of Mexico. In this war we first meet with the Aztec name Motecuzoma, afterwards so famous in its Spanish form Montezuma. About 1430 took place the triple alliance of the Acolhua, Aztec and Tepanec kings, whose capitals were Tezcuzco, Mexico and Tlacopan, the latter standing much below the other two. In fact the rest of native history may be fairly called the Aztec period, with its standing the magnificence and culture which make Tezcuzco celebrated under Nezahualcoyotl and his son Nezahualpilli. When the Culhua capital was taken and burned, the Mexicans swayed east far beyond the valley plateau of its origin, and the gods of conquered nations around had their shrines set in Tenochtitlan in manifest inferiority to the temple of Huitzilopochtli, the war-god of the Aztec conquerors. The rich region of Quauhnauac became tributary; the Mitaztec country was invaded southward to the Pacific, and the Xicalanca region to what is now Vera Cruz. It was not merely for conquest and tribute that the fierce Mexicans ravaged the neighbou- rlands, but they had a stronger motive than either in the desire to obtain multitudes of prisoners whose hearts were to be torn out by the sacrificing priests to propitiate a pantheon of gods who well personified their bloodthirsty worshippers. (E. B. T.)

Ancient Civilization.

While the prairie tribes of America lived under the loose sway of chiefs and councils of old men, the settled nations of Mexico had attained to a highly organized government. This may point to the gradual building up of a balanced power maintained in the federation of Mixco-Tecuo and Tlacopan, where each king was absolute in his own country, but in war or other public interests they acted jointly, with powers in something like the Republic of the United States. They divided their land into provinces, which was a district of two sisters; that is, they divided the land into two parts, each part of which was passed from one family to the next. The king himself ruled the provinces, and each province was governed by an appointed governor. The Aztec king was a great statesman, and he was always looked on as an elaborate device for securing practical advantages, seems rather to have arisen out of the law of choice among the descendants of the female line, found in American tribes of much lower culture. Something like this appears in the succession of kings of Tezcuzco and Tlacopan, which went to sons by the principal wife, for some was usually the Aztec royal family. The Mexican chronicles, however, show instances of the king's son succeeding or of powerful chiefs being elected to the kingship. The term republce is sometimes used to denote this little state, as if it were a federation of four chiefs, with an assembly of nobles. In the Zapotec district the Wyatoo or high-priest of Zapoa was a divine ruler before whom all prostrated themselves with faces to the ground; he was allowed to show his foot to touch the earth, for it was only seen in a litter. The accounts of the palaces of the native kings must be taken with some reserve, from the tendency to use descriptive terms not actually descriptive, but carried over from ancient legend. (Palaces, etc.) columns of porphyry and jasper supporting marble balconies might perhaps be built as well as described as they were, but the roofs of palaces and terraces must have been more remarkable for number and extent than architectural grandeur, being but low one-storied buildings. The principal palace of Mexico consisted of hundreds of rooms ranged round three open squares, the largest that one of the companions of Cortes records having four times wandered about till he was tired, without seeing the whole. Not less remarkable was the palace of Tezcuzco, surrounded with its groves and pleasure-gardens; and, though now hardly anything remains of the buildings above ground, the neighbouring hill of Tezocotmachi still has its stone steps and terraces; and the immense embankments carried away by the conquering Spaniards still remain, as natural monuments of the Spanish conquest and the building character of the Aztecs. The rulers of Monteazua, the old capital of Chapultepec, but these as well as the hanging gardens have been destroyed, and even the groves of ashuhuehu (cypress) remain of the ancient beauties of the place. That in the palace gardens flowers were permitted to bloom also is thus described: 'There were near fresh and salt pools fit for each kind, that all kinds of birds and beasts were kept in well- appointed zoological gardens, where there were harems as well as harem gardens; the right of naming each flower was reserved to the patron gods, and the whole the description of natural history which was really beyond the European level of the time. From the palaces and retinues of thousands of servants attached to the royal service may be inferred at once the most extensive range of wealth and power and the supreme rulers of the free men and shopkeepers of the whole land. In fact, the idea of a nobility that of the Aztecs was a numerous and powerful class of nobles, the highest of whom (tlatocani) were great vassals owing little more than homage and tribute to their feudal lord, while the natural result of the unrolling of the noble class was that the king to keep them in check increased their numbers, brought them to the capital as councillors, and balanced their influence by military and household officers, and by the professional Aztec soldiers. The power of the nobles was one of privileges of rank and dignity, but substantial power over the plebeian or peasant class (macehualtli). The greatest estates belonged to the king, or had been granted to military chiefs whose sons continued to hold them under the king, who was the supreme ruler or village community still survived, and each freeman of the tribe held and tilled his portion of the common lands. Below the freemen there were slaves, whose labor was sold to the army, or children sold by their parents. Prisoners of war were mostly doomed to sacrifice, but other classes of slaves were mildly treated, retaining civil rights, and their children were born free, except the superior courts of law formed part of the palace, and there were tribunals in the principal cities, over each of which presided a supreme judge or ciuchaoac, who was irremovable, and whose criminal decisions not even the king might reverse; he appointed the lower judges and heard appeals from them; it is doubtful whether he judged in civil cases, but both kinds of suits were heard in the court below, by the tlatoahcahis and his two associ- ates, of whom the latter was a professional lawyer, and the former the maintenance of the judges, and indeed nothing gives a higher idea of the elaborate civilization of Mexico than this judicial system, which culminated in a general court and council of state presided over by the king. The leading figures in these courts and tribunals of the king. The system was described in picture- writings, of which some are still to be seen; sentence of death was recorded by drawing a line with an arrow across the portrait of the condemned, and the chronicles describe the barbaric solemnity with which the judges shaved the captive's head, burned the throne in the divine tribunal, with one hand on an ornamented skull and the golden arrow in the other. Among the resemblances to modern times in the Aztec government, perhaps the most extraordinary is the belief that the king was divine, and that his earthly body had been preserved to him by the gods, and that the king had been at his own pleasure able to appoint the day when he was to die; he who pillaged in the market was then and there beaten to death, and he who insulted Xipe, the god of the gold- and silver smiths, by stealing his precious metal, was skinned alive and sacrificed to the offended deity. Though aloe-beer or "paluque" was allowed
for feasts and to indulge in moderation, and old people over seventy
seem to be represented in one of the picture-writings as having liberty of
the describing god, without the four-storied temple, the shrines
and young women stoned. For such offences as witchcraft, fraud,
remarking landmarks, and adulteriy the criminal had his heart cut
tout and was placed in torment. Murders were punished with lesser
punishments were harsh, such as that of slanderers, whose
hair was singed with a pine-torch to the scalp.

Based on conquest as the Aztec kingdom was, and with the most
bloody history of any ancient Mexican people, it is not strange
these ancient Aztecs were a fighting community. To be a tried soldier was the road
to honour and office, and the king could not be enthroned
still he had added to his own hand taken captives to be butchered
on the war-god's altar. Captives were even dressed in the most
suitable garments worn by the chief victor. Many of these captives were
promoted for acts of daring, and the children of chiefs were
regularly trained to war, and initiated by being sent into battle with
very young to take the place of the old veterans. The future rise depended on how many captives he took, but not in front of
with warlike enemies; by such feats he gained the dignity of wearing
bead or silver, and decorated with feathers, as well as a great number of
Spanish invaders glad to adopt it. The archers shot well with strong bows, though their arrows were generally tipped only
with stone or bone; their shields or targets, mostly round, were of
orchids or roots of certain kind, and these were decorated with yellow,
blue, or brown, and were sometimes hauled with a spear-thower or atlatl,
of which pictures and specimens still exist, showing it to be similar in
its form to the modern type. The characteristic weapon of the Mexicans was the macuahuitl or "hand-wood," a club set with two rows of large sharp obsidian flakes, a well-directed blow with which would cut down man or horse.
These two clubs and the long, extended arms of the statues were supposed to be the savage forms, while on the other hand the military organization was in
equally respects to that of an Asiatic nation, with its regular companies commanded each by its captain and provided with its
standards. The ancient Mexican army was of a very orderly fashion,
lining of several divisions, each numbering eight thousand men; but the tactics of the commanders were quite rudimental, consisting merely in the clash by arrows and javelins at a distance, gradually
narrowing in to hand-to-hand fight with clubs and spears, with an occasional feigned retreat to draw the enemy into an ambush.
Fortification was well understood, as may still be seen in the remains of walls and enclosures on hillsides and in steep ravines, while
town-city like Mexico had the water approaches defended by
flotillas of boats and the causeways protected by towers and ditches;
even when the town was entered, the pyramid-temples with their surmounting temple of the goddess of the sun, were taken by
assault, by the entire population. These were adorned with many houses
fought on foot to invade another nation without a solemn
embassy to warn their chiefs of the miseries to which they exposed themselves by
fighting. The Aztec war temples were taken again with a
victory by a declaration of war, but in Mexico this degenerated into a ceremo
nial farce, where tribute was claimed or an Aztec god was offered
to be worshipped in order to pick a quarrel as a pretext for an invasion
against any of his enemies. The Aztec system of religion and politics
and to meet the priests' incessant demands for more human sacrifices.

Among the accounts of the Mexican religion are some passages
referring to the belief in a supreme deity. The word teoclat, god, has
been thought in some cases to be a form of the god of war and
victories, but its meaning is that of deity in general, and it is
applied not only to the sun-god but to very inferior gods. It is
related that Nezahualcoyotl, the poet-king of Texcoco, built a nine
storied temple with a starry roof above, in honour of the invisible
day called Tloquehuanahui, "he who is all in himself," or Ipal
nomoli, he by whom we live," who had no image, and was pro
vided not by the gods seething in the bowels of the world and the
divinities, however, seem to have had little or no place in the popular
faith, which was occupied by polytheistic gods of the ordinary
barbaric type. Texcatlipoca was held to be the highest of these, and their
worship was always connected with the earth, and was expected
to appear in the flower storms to receive this sign of their coming. He
 plains an ancient deity of the race, for attributes of many kinds are
seen in the decorations of many temples. The Aztecs called their
ancient deity of Cholula, there had been old rivalry. As is related
in the legends, Quetzalcoatl came into the land to teach the
floor, to work metals and to rule a well-ordered state; the two gods
dressed in feathered dress and with their heads in the shape of
and having the head of the plumed serpent, and having the head
of the plumed serpent, and having in their hands the wands of the
and having the head of the plumed serpent, and having in their hands the wands of the
dancing Quetzalcoatl to drink the magic pulque that sent him
roaming to the distant ocean, where he embarked in his boat
and disappeared from among men. These deities are not easily

1One of the most important sources for the ancient Mexican traditions and myths is the so-called Codex Chichimecopaoca, a manuscript in the Mexican language discovered by Abe Leob
1891, and published in the Anales del museo nacional de Mexico, tom. iii., app. pp. 7-79; but in this edition the Mexican text is very corrupt, and the two Spanish translations are by no means exact. The
publication by the University of Chicago by Professor E. Selin. Another very important MS. was discovered by Dr Lehmann, in Guatemala. It is the MS. of Father Francisco Ximenes, Historia de la Provincia de San Vicente de Chapa y de Guatemala, in three books, of which the Spanish translation of the Quiché myths or the "Popol-Vuh." The MS. was bought at the expense of the Duke of Loubat, who decided to present it, after the death of Dr Lehmann, to the Royal Library of Berlin.
MEXICO

ANCIENT CIVILIZATION

chants, fasting and other austerities, but there are some peculiarities of detail. Prayers and other formulas have been copied down by Sahagun and other chroniclers, of endless prolixity, but not without occasional touches of pathos. The gods to whom they were addressed were not the usual gods of the ordinary European model from which they could have been imitated; but at the same time it must be remembered that they came down in Spanish writing, and not untouched by the pen of the chronicler of the day. There were there a good many of sheep, an animal unknown to the Mexicans. As to sacrifice, maize and other vegetables were offered, and occasionally rabbits, quails, &c., but, in the absence of cattle, the principal sacrifice was offered to the food-god. Every feast was an occasion for a sacrifice, and the popularity of the individual sacrifice at the feast. Incense was commonly used, especially the copalú (copal) well known to us for varnish; little terra-cotta censers are among the commonest of Mexican vehicles. The sacred species the priests used at special occasions, and drawing blood from the arms, legs and body, by thrusting in acol-thorns, and passing sharp sticks through the tongue, was an habitual act of devotion rendered visible to the simulation of the tongue, was an habitual act of devotion rendered visible to the fire. The calendar of religious festivals for the Mexican year has been preserved. Each 20-day period had one or more such celebrations. In the month of the diminution of waters, the Tonatiuh, or God of Waters, was represented by a procession of priests with music of flutes and trumpets carrying on plumed litters infants with painted faces, in gay clothing with coloured paper wings, to be sacrificed on the mountains or in a whirlpool of the sea. The ceremony was often carried on if the sun had so may have been a customary formality, for the religion of these nations must have quenched all human sympathy. In the next month, February, the captives, however, came ashore, and called the "slaving of men" from the human victims being slayed, after their hearts were torn out, for young men to dress in their skins and perform dances and sham fights. The succeeding festival of Calvandt, in April, was followed by the priests of Texcoco. The stone knives were prepared with which a hole was cut through the tongue of each, and numbers of sticks passed through. For the great feast of Tlaloc, the year Commemoration and noiset of the captives of the year had been chosen as the incarnation representative of the god, and paraded the streets for public adoration dressed in an embroidered mantle with feathers and garnished with his head and a trinket like a king; for the last month they married him. A woman in state and girls representing four goddesses; on the last day wives and pages escorted him to the little temple of Tlacochcalco, where he mounted the throne and into the mountain, from whose mouth each year a royal bundle of acolytes. The mound and the fire were a symbolic farewell to the gods of the world, for as he reached the top he was seized by the priests, his heart torn out and held up to the sun, his head split on the tzompantli, and his body eaten as sacred food, the people drawing from his fate the moral lesson that riches and pleasure may turn into poverty and sorrow. The manner of the victim's death in these festivals afforded scope for variety; they dressed them and made them dance in character, threw them into the fire for the fire-god, or crushed them between two balanced stones at the harvest-festival. The ordinary pleasures of festivals were mingled with all this, such as dances in beast-masks, sham fights with clubs, feasting and dancing, but the most important and most dread of all was the fire ceremony, which was a sickening lutechery followed by a canibal feast.

The Mexican priesthood was much concerned with the art of picture-writing, which they used systematically as a means of recording events from the past, and constructing calendars of years and recording the historical events which occurred in them. Facsimiles of some of these interesting documents, with the Mexican calendar of timekeeping, are to be found in Kingsborough; splendid reproductions of the beautiful Mexican and Mixteco-Zapotocan codices have also been published at the expense of the Duke of Loubat and by the Junta Colombina (Mexico, 1892). Gods are represented with their appropriate attributes—the fire-god hurling his spear, the moon-goddess with a shell, &c.; the scenes of human life are pictures of warriors fighting with clubs and spears, men paddling in canoes, women spinning and weaving, &c. An important step towards phonetic writing appears in the picture-names of persons and places. The simplest forms of these signs signify the name of the, as where Chapultepec or "grass-skirt hill" is written, or where the word for "mountain hill," or a stone with a cactus on it stands for Tochoco or "stone-cactus," the founder of Tenochtitlán. The system had, however, risen to a high state when objects are drawn to represent not themselves, but the syllables forming their names, as where a traits and eagle, a pricker, and a hand are put together not to represent these objects, but in order that the syllables of their names ma-gnusco or ne-moza should spell the word manusco (see Appendix to the Mexican History by Brasseur, Hist. du Mexique, i. 68). The analogy of this to the manner in which the Egyptian hieroglyphics passed into phonetic use is of the most instructive character. The Aztec numerals, which were vigesimal or reckoned by scores, were depicted by a circle of figures up to 20, which was represented by a flag, 400 (a score of scores) by a second flag, 8000 (a score of scores by a) by a but for convenience these symbols might be halved and quartered, so that 534 might be shown by one feather, one quarter of a feather, one quarter of a feather, one half of a flag, and four dots. The Mexican calendar depended on the combination of numbers with picture-signs, of which the four principal were the rabbit, reed, flint, house—tocalli, acatl, tecpatl, calii. The cycle of 52 years was reckoned by combining these signs in rotation with numbers up to 13, thus: The 13th day of the 8th month of the 10th year of the 4th month of the 6th day of the 13th month of the 9th year of the 41st sign. This calendar may be exactly illustrated with a modern pack of cards laid out in rotation of the four suits, as, ace of hearts, 2 of spades, 3 of diamonds, 4 of clubs. The Aztec calendar was a pictorial calendar; the days of the year, the same method is carried further, the series of twenty-day-signs being combined in rotation with numbers up to 13; as this cycle of days only reaches 260, the year is completed by another, the period of 360 days, by referring to the signs of the 6th day of the 13th month of the 9th year of the 41st sign and the 365th day. It is plain that this rotation of signs served no useful purpose whatever, being less convenient than ordinary counting such as the Mexicans themselves used; but by referring to the 20-day periods had each a name like our months, and their days had signs in regular order. Its historical interest depends on its resemblance to the calendar-system of central Mexico, and the periods of the year in the same order. The series of signs are thus combined to reckon years, months and days; for instance, the Mongol cycle of 60 years is recorded by the zodiac or series of 12 signs—mouse, bull, tiger, &c., combined in rotation with the five male and female elements—fire, earth, iron, waterwood; as "male-fire-bull" year, &c. This comparison is worked out in Humboldt's Vues des Cordillères, as evidence of Mexican civilisation being borrowed from Asia. Naturally the Mexican calendar-system lent itself to magic in the same way as the similar zodiac-signs of the Old World, each person's fate being affected by the qualities of the signs he was born under, and the astrologers' predictions were extremely accurate. The Aztec festivals the most solemn was that of the chinmopilli, or "year-binding," when the 52-year cycle or bundle of years came to an end. The diet of the dead was kept up, and on the last day after sun-dawn, the person dressed in the garb of gods, set out in procession for the hill of Huisachitla, there to watch for the approach of the Pleiades to the zenith, which gave the auspicious signal for the lighting of the new fires. The finest of the captives was solemnly burned on his breast by the wooden drill of the priest; then the victim's heart was torn out, and his body flung on the pile kindled with the sacred flame. From the ashes of this sacrifice the fire was taken to the country round saw with joy the flame on the sacred hill, and hailed it with a thank-offering of drops of blood drawn from their ears with sharp stone-likes. Swift runners carried burning brands to rekindle the fires of the land, the sacred fire on the teocalli of the war-god blazed up again, and the people began with feasting and rejoicing the new cycle.

Education. Education. Education. Education. After the birth of a child, the tonalpouochtli or "sun-calculator" kept a count of the days after the birth, and fixed the time for its solemn lustration or baptism, performed by the nurse with appropriate prayers to the gods, if a toy shield and bow were provided if it was a boy, or a toy spindle and distaff for a girl. As the child grew the festivals and occasions of the picture-writing, to be seen in Kingsborough, shows the details of the boy's or girl's education, from the early time when three small and no more than five notches on the symbol may have been represented, a bundle of half a tortilla or corn-cake shows its allowance for each meal; as they grow older the fads are seen beginning to carry burdens, paddle the canoe and fish, while the girls learn to spin and weave, grind maize and cook—good conduct being enforced by punishments of increasing severity, up to prickings their bodies with acol thorns and holding their faces over burning chilies. The schools were extensive buildings attached to the temples, where from an early age boys and girls were taught by the priests to reverence the sanctuaries and keep up the sacred fires, to fast at proper seasons and draw blood for penance, and where they received moral teaching. A young person, a "incensor" was trained to the use of weapons and sent early to learn the hardships of war; children of craftsmen were usually taught by their fathers to follow their trade; and for the children of nobles there was elaborate instruction in history, picture-writing, astrology, religious doctrines and laws. Marriages depended much, as they do still in the East, on comparison of the horoscopes of the parties to ascertain if their birth-signs were compatible. Old women were employed as go-between, the ceremonies conducted by a priest who after formal exhortations united the young couple by tying their garments together in a knot, after which they were usually placed on a huge bed, and after the performance of the marriage ceremony, the pair entered together on a four-days' fast and penance before the marriage was completed. Funeral rites of the Mexicans are best seen in the ceremonies at the death of a nobleman. In state was provided by the priest with a jug of water for his journey, and with bunches of cut papers to pass safely through each danger of the road—the place where the two mountains strike
MEXICO

ANCIENT CIVILIZATION]

together, the road guarded by the great snake and the great alligator,
the eight deserts and the eight hills; they gave him garments to
protect him from the cutting wind, and buried a little dog by his side
to carry him across the nine waters. Then the royal body was

invested in the mantles of his patron-gods, especially that of the
war-god, for Mexican kings were warriors; on his face was placed
a mask of turquoise mosaic, and a green chalchihuite-stone as a
heart between his lips. In older times the dead king was buried
on a throne with his property and dead attendants round him. But
after cremation came in a mourning procession of servants and chiefs
carrying the body to the funeral pyre to be burnt by the demondressed priests, after which the crowd of wives and slaves were
exhorted to serve their lord faithfully in the next world, were
sacrificed and their bodies burnt. Common people would not thus
be provided with a ghostly retinue, but their simpler funeral ceremonies were as far as they went similar to those of their monarch.
The staple food of the Mexicans before the conquest has continued
with comparatively little change among the native race, and has
even been adopted by those of European blood. Maize

where, as in the Hindu j&m, the trees and bushes were
burnt and the seed planted in the soil manured by the ashes.
sharp-pointed planting stick, a wooden shovel, and a bronze-bladed
hoe called a coatl were the simple implements. The Mexicans
understood digging channels for irrigation, especially for the cultivation of the cacahuatl, from which they taught the Europeans to
prepare the beverage chocollatl; these native names passed into
English as the words cacao, or coco and chocolate. Other vegetables adopted from Mexico are the tomato (tomatl) and the chilli,
used as flavouring to native dishes. The maize was ground with a
stone roller on the grinding stone or metlatl, still known over Spanish
America as the metate, and the meal baked into thin oval cakes called
by Aztecs tlaxcalli, and by Spaniards tortilla, which resemble the
chapati of India and the oatcake of Scotland. The Mexicans were
also skilful makers of earthen pots, in which were cooked the native
beans called by the Spanish frijdes, and the various savoury stews

rk
the metals by means of a reed-blowpipe and cast them
solid or hollow, and were also skilled in hammered work and
chasing, as some fine specimens remain to show, though the famous
animals modelled with gold and silver, fur, feathers and scales
have disappeared. Iron was not known, but copper and tin ores
were mined, and the metals combined into bronze of much the same
alloy as in the Old World, of which hatchet blades and other instruments were made, though their use had not superseded that of
obsidian and other sharp stone flakes for cutting, shaving, &c.
Metals had passed into a currency for trading purposes, especially
quills of gold-dust and T-shaped pieces of copper, while coco-beans
furnished small change. The vast size of the market-squares with
their surrounding porticos, and the importance of the caravans of
merchants who traded with other nations, show that mercantile
had risen into some proportion to military interests. Nor was the
wealth and luxury of Mexico and surrounding regions without a correThe stone sculptures

by Humboldt, as well as the ornamented woodwork,
feather-mats, and vases, are not without artistic merit. The oftencited poems attributed to Nezahualcoyotl may not be quite genuine,
but at any rate poetry had risen above the barbaric level, while the
mention of ballads among the people, court odes, and the chants of
temple choirs would indicate a vocal cultivation above that of the
instrumental music of drums and horns, pipes and whistles, the
latter often of pottery. Solemn and gay dances were frequent, and
a sport called the bird-dance excited the admiration of foreigners
for the skill and daring with which groups of performers dressed as
birds let themselves down by ropes wound round the top of a high
mast, so as to fly whirled in circles far above the ground. The ballgame of the Mexicans, called tiachtli, was, like tennis, the pastime
of princes and nobles; special courts were built for it, and the ball
of india-rubber (perhaps the first object in which Europeans became
acquainted with this valuable material) Blight not be touched by
the hands, but was driven against the walls by blows of the knee or
elbow, shoulder or buttock. The favourite game of patolli has been
already mentioned for its similarity to the pachisi of modern India.
The accounts given by Spanish writers of the Central Americans
in their state after the Spanish conquest are very scanty in com,

parison with the voluminous descriptions of Aztec life.
They
bring out perfectly, however, the fact of close connexion between
the two civilizations. Some Central-American peoples
Ctntralwere actually Mexican in their language and culture,
American
especially the Pipits and a large part of the population
of Nicaragua.
The investigations made by Dr Walter
Lehmann in Central America (1907-1909), prove that these Mexican
elements were extended through Guatemala, Salvador, a small part of
Nicaragua (the territory of the Nicaraos) and on several places in the
peninsula of Nicoya (Costa Rica) amongst the autochthonous Chorotega or Mangue. It is an error of the Spanish authorities to pretend
that the Pipil civilization in Guatemala and Salvador is not older
than the time of King Ahuitzotl (c.
1482-1486). The language
spoken by the Pipils of Salvador (Balsam Coast) is a very old dialect
of the Mexican language of the highland of Mexico. It has preserved
in the conjugation and in the formation of the
plural older forms
than the classical Nahuatl itself. The
from
separation of the Pipils
the chief tribes of the Nahuatl branch happened centuries before
the conquest, and they
developed a singular and characteristic
civilization, which can be seen in the wonderful stone-reliefs and
sculptures of Sta Lucia de Cozumalhuapa on the Pacific coast of

Guatemala.
Dr Lehmann's archaeological and
in Salvador

linguistic researches, especially

and Nicaragua,

also enabled him to prove another very
that these Pipils, who may be descendants from
important
the peoples of_the Mexican Plateau, migrated into territories previously occupied by an older race of Mayan origin. The archaeological and linguistic evidence proves also that a great part of
Salvador and Honduras was once occupied by peoples of the Maya
race Pokomam, Chord and perhaps other unknown tribes. They
left typical Mayan ruins in Honduras (Tenampua) and in Salvador
(Opico near Tehuacan, Quelepa near San Miguel), which seem,
however, to be destitute of Mayan hieroglyphic inscriptions. The
easternmost limit of prehistoric Mayan civilization, on the Pacific
coast of Central America, is Fonseca Bay, with the island of Zacate
fact, viz.

Grande.
It is noteworthy that archaeological objects of the
charactertype
istic of northern Honduras (Ulloa Valley) have been found on the
Pacific coast of Salvador.

A strange stone sculpture of the so-called

Chac-Mol type, known before only from the country of the Tarascs,
from Tlaxcala and Chichen Itza, was discovered in Salvador
(Ahuachapan).
In the nearly unexplored central
of Nicaragua Dr Lehmann
part
found fragments of painted polychrome clay pottery similar to
objects known from the Ulloa Valley (Honduras) amongst other
ceramic pieces which seem to have been left by the ancestors of the

that Mayan civilization cannot be traced in any
other part of Nicaragua or Costa Rica.
The above-mentioned
prehistoric Mayan peoples lived in contact
"
"
nations and with another little-known civilized
with
barbarous
race.
The barbarians belonged to the great family of the SumoMisquito Indians, the civilized race was that of the Chorotega or
Mangue (Dirian, Orotinan, &c.). The Sumo-Misquito Indians
occupied the Atlantic coast and the interior of Nicaragua and
Honduras, where they still live in small tribes a dialect of the hitherto
unknown Sumo languages is the Matagalpan, now extinct in Nicaragua, and nearly identical with the Matagalpan is the language spoken
by the Indians of Cacaopera in Salvador (Ultra-Lempa territory).
There is no doubt that, at the time of the Pipil invasion, tribes of
the Sumo-Misquito family were the immediate neighbours of the
names
Pipils towards the east and north. This fact is proved by the
of some places in Salvador, e.g. Santiago Nonohualco, San Juan
It is significant

;

Nonohualco and San Pedro Nonohualco. The word Nonohualco
the Mexican language a place where a language changes,
where another idiom begins. To the east of the three places whose
"
names are compounded with
Nonohualco," must have dwelt, in
the time of the Pipil Indians, the Nonoualca, called also by Mexican
signifies in

The western neighbours of the Sumo
Indians were and are (though few still survive) the Lenca Indians,
who formerly occupied large parts of Honduras. A linguistic relationship can be established between all the Indian languages spoken
on the Atlantic coast and in the interior of Nicaragua and Honduras.
Several tribes, such as the Paya (or Poya) and the Jicaques, form
together with the Lenca, Sumo (Matagalpa, Tauakhca and Ulua)
and Misquito one great family.
The position of the isolated Xinca (or Sinca) Indians, regarded
from this point of view, becomes very interesting. There are
scientific reasons to believe that the Xinca also belong to the same
It
great family as the Lenca, Jicaques, Paya, Misquito-Sumo.
may be possible either that these tribes are the autochthonous inhabitants who dwelt in Guatemala, Salvador, Honduras and Nicaragua
before the immigration of the prehistoric Maya peoples; or else that
they invaded this region after it had been deserted by a prehistoric
oriental branch of the Maya family.
The Chorotega race had its centre in Nicaragua (Pacific coast) and
at one time extended thence as far as Guanacaste (Costa Rica) at

tribes Chontales or Popoloca.

;


ANCIENT CIVILIZATION

Another time it extended as far as Honduras (actual department of Choluteca) and into eastern Salvador as far as the state of Chiapas in Mexico, where the Chortego peoples still occupied among the Maya. After a dislocation of the Chupan section of the Maya, the Classic period of the Maya culture lapsed into a quiescence behind that of the Mayan and Toltec peoples of the Mitla originally from the Teotihuacan. The Maya, Celts, Reusen, Sumo, and Chicana peoples were the last to form the Maya tribe. The territories of all these tribes may be considered a single place name in the Maya language, or more accurately, a place name of several separate names, including those of the Matagarup, Lower Lencas, and Upper Lencas. Considered as a whole, the Maya culture included several different tribes, all of which are considered in this volume.

The Maya was a pre-Columbian civilization that developed in the area of modern-day Mexico, Guatemala, Belize, Honduras, and El Salvador. The Maya are known for their complex writing system, advancements in mathematics, architecture, and astronomy. The Maya civilization flourished from the 3rd century BCE to the 9th century CE, and their influence continues to be felt in modern times through their art, literature, and religion.

The Maya civilization is divided into three main periods: the Early Classic, Middle Classic, and Late Classic. The Early Classic period began around 250 CE and ended around 350 CE, the Middle Classic period lasted from 350 CE to 650 CE, and the Late Classic period ran from 650 CE to 900 CE. The Mayan Empire reached its peak during the Late Classic period, with the rise of cities such as Tikal, Uaxactun, and Copan. The Maya cities were centers of trade, religion, and learning, and they built elaborate pyramids and palaces.

The Maya civilization was also known for its complex writing system, which is one of the most advanced in the Americas. The Maya wrote in hieroglyphs, using a combination of logograms and syllabic signs. The Maya were also skilled astronomers, and they used their knowledge of astronomy to create a calendar system that was more accurate than the one used in Europe at the time.

However, the Maya civilization was not immune to decline. Around 900 CE, the Maya civilization began to decline, and by 1200 CE, most of the major Maya cities had been abandoned. The reasons for this decline are not fully understood, but it is likely a combination of natural and human factors, such as climate change, overpopulation, and political instability.

The Maya civilization had a significant impact on the history of the Americas, and their legacy continues to be felt today. The Maya were one of the most advanced civilizations in the Americas, and their achievements continue to inspire people around the world.

II.—Colonial Period. 1520–1821.

The conquest of Mexico by the Spanish forces under Hernando Cortes (q.v.) in 1520, and the death of the last Aztec emperor, Guatemino, introduced what is known as the colonial period of Mexican history, which lasted down to the enforced resignation of the last viceroy, O'Donjuo, in 1821. During these three centuries, after a brief but most unsatisfactory experience of government by the Spanish conquerors, Mexico was ruled over New Spain. Of these a few were ecclesiastical: two had two terms of office; only two or three were of native birth, and their previous official life had always been passed in other parts of the Spanish dominions.

New Spain was one of four great vicerealties, the other three being New Granada, Buenos Aires and Peru; its viceroy ruled over districts differing in status and with overlapping and conflicting authorities, some of these being appointed directly by the king of Spain, and responsible to him, New Spain, including the audiencias or judicial districts of Manila, San Domingo and Guatemala, and the viceroy had some sort of authority over them; but in its narrower meaning it comprised the audiencia district of Mexico and the subordinate audiencia district of Guadalajara, which together extended from Chiapas and Guatemala to the beyond the eastern boundary of the modern state of Texas and northwards, eventually, to Vancouver's Island. In the course of the 18th century this came to consist of the following divisions: (1) the kingdom of Mexico, which included the province of Oaxaca; (2) the kingdom of New Mexico, in its widest meaning includes Durango, Sonora with Sinaloa, Coahulla, Texas (from Corpus Christi Bay to the mouth of the Mercedon in the present state of Louisiana), and the two Californias.

The government councils also advised the viceroy in matters of administration; and, as with other officials, his career was subject at its close to a formal examination by a commission—a process known as "taking his residencia." Local government till 1786 was largely in the hands of alcaldes mayores and corregidores, the latter established in 1531 to look after the Indians, and both appointed by purchase. Towns, which were to some extent founded after the conquest as centres of civilization for the Indians, were governed by civic officials appointed in the first instance by the governor of the province, but subsequently as a rule purchasing their posts.

**Government and Organisaton.**

The church rapidly supplemented the work of the conquerors. The first Franciscan mission arrived in 1524; other orders followed. The announcement of the apparition of the Virgin to an Indian near Mexico City provided a place of pilgrimage and a patroness in Our Lady of Guadalupe; and the friars ingeniously used the hieroglyphic writing for instructing the natives in the Christian doctrine, and taught the natives trades, for which they showed much aptitude. The university of Mexico was founded in 1553. The Jesuits established themselves in 1572, devoting themselves actively to the education both of whites and of natives, and were a powerful factor in the exploring and civilizing of the northern districts. The Inquisition was introduced in 1571. With the natives south of the latitude of Tampico there was little trouble after the Mixtón War (in Guadalajara) in 1540–1562, save for occasional risings in Yucatán, Tampico, and in 1711 in the Nayarit mountain region west of Zacatecas, and Tamaulipas was conquered in 1748; but the wild Indians of Sonora and New Mexico gave constant trouble to the missions and outlying settlers. There were occasionally riots due to scarcity of corn (notably in Mexico itself in 1692). As in other Spanish possessions, Indian labour was replaced or supplemented by that of negro slaves, but these were almost wholly confined to the coast regions of Vera Cruz and Acapulco, and early in the 19th century there were only some 16,000 in all. Among the Spanish troops brought women, there was much mixture of races. Among the pure whites—who were practically all of Spanish extraction—there were two well-defined classes, the Gachupines or chppetones, Spaniards born in Europe, said to be so named in allusion to their spurs, from Aztec words meaning "prickers with the foot," and the native-born or creoles; the former, though a small minority, had almost all the higher positions both in the public services and in commerce. Besides these there were five well-defined castes: mestizos (Indian and white); Acalans or zamoranos (Indian and mulatto); mulattoes (negro and mulatto); Negroes or negroes. There were about a dozen intermediate "named varieties," of which the salto-atras (tending away from white) and lente en laire (tending towards white) may be mentioned; and many of the last named eventually passed into the Creole class, sometimes by the decree of a court. The fact that the trade route to Manila passed through Vera Cruz, Mexico City and Acapulco entailed the settlement also of a few Chinese and Malays, chiefly on the Pacific coast. The natives were subject to tribute and kept in perpetual tutelage: divided at the conquest, with the land, as serfs of the conquerors, in reparaciones or encomiendas, they were gradually freed at an early date from their servage, and allowed to sell their labour as they pleased; they were, however, to a great extent kept in villages or settlements, compelled to cultivate land which they held for their life only, and strictly controlled by the friars or the priests. Their numbers were several times seriously reduced by the smallpox, apparently analogous to yellow fever, but not attacking the whites, and unknown before the conquest. They were allowed to buy their freedom gradually at rates fixed by the judicial authorities, and slavery seems never to have taken much hold except in the coast region.

Of the events of this period only a bare outline can here be given. The term of office of the first viceroy, Antonio de Mendoza, was marked by the Mixtón War, by an attempt to suppress the encomienda system, and by a violent epidemic among the natives. Under his successor, Velasco, the measures taken for the relief of the natives provoked the landowners to a reaction, (pressed with great severity) to set up Cortés' son as king of New Spain. In 1568 the island of Sacrificios, near Vera Cruz, was seized by John Hawkins (q.v.), who was surprised by the Spanish fleet accompanying the new viceroy, de Almansa, and escaped with Sir Francis Drake (q.v.), but without the remaining ships of his squadron. In 1572 and 1578, however, Drake took abundant Leading Events:

- 1550: The establishment of the Nueva España
- 1553: Foundation of the University of Mexico
- 1571: Introduction of the Inquisition
- 1580: Foundation of the Jesuit mission in Mexico
- 1692: Decline in the Indian population due to smallpox
- 1711: Uprising in Nayarit
- 1748: Conquest of Tamaulipas
- 1791: First Mexican War of Independence
- 1821: Independence of Mexico

The events of this period formed the foundation of modern Mexico and its culture.
vengeance, and in 1587 Cavendish captured the Manila galleon—a success repeated in the next century.

For the next sixty years an urgent question was the prevention of floods in the capital. Situated on the lowest of four lakes, the city was only 4 ft. above the level of the

age of the Capital lowest, and was flooded on an average once every twenty-five years. It had been protected under the native kings by a system of dikes, which was added to under the earlier viceroys, but serious inundations in 1553 and 1580 flooded the city, and the latter suggested the relief of the highest lake, that of Zumpano, by a tunnel carrying its chief affluent into a tributary of the Panuco, and so to the Atlantic. This, however, was not then undertaken, and when mooted again in 1603 was opposed as certain to involve a heavy sacrifice of Indian life. Another inundation, in 1604, suggested the transfer of the city to Tacubaya, but the landowners opposing and the city being again inundated in 1607, the Nochistongo tunnel was begun under the auspices of a Jesuit, Enrico Martínez, and roughly completed in eleven months. It passed under a depression in the mountains of the extreme north of the valley. Humboldt states that it was 6000 metres long, 3½ wide and 4 high. But it did nothing for the southern lakes, so that a further system of dikes was recommended in preference, in 1614, by the Dutch engineer Adrian Boot; it was inadequate for its work and, not being lined with masonry, it was liable to be choked by falls. Repairs were suspended in 1673, and a further inundation, with great losses of life, occurred from 1629 to 1634. The removal of the city was again mooted and, though sanctioned by the king of Spain, successfully opposed by the landowners. Another flood occurred in 1642. After a disastrous attempt to enlarge the tunnel in 1675, it was eventually converted into an open cutting, but the work was not finished till 1789, and the bottom was then 29 ft. 6 in. above the level of the lowest lake. The drainage was only satisfactorily accomplished at the end of the 19th century (see below).

A negro revolt in the Vera Cruz region (1600) and an Indian rebellion in Sinaloa and Durango may be mentioned among the events of the earlier part of the 17th century. The Church and State. regular and secular clergy had early come into conflict, frequently over the tithe and the control of the Indians; and in 1621, the marquis de Gelves, an energetic reformer, who as viceroy favoured the appointment of the regulars to deal with the natives, came into conflict with Archbishop Serna of Mexico, who placed the city under interdict, excommunicated the vicaroy and constrained him to hide from the mob. Some years later the bishop of Puebla, Juan de Palacios y Mendoza, transferred many native congregations from the friars to secular priests, and subsequently, in 1647, came into conflict with the Jesuits, whom he excommunicated, but who eventually triumphed with the aid of the Dominicans and the archbishop. The power of the church may be judged from the petition of the Ayuntamiento of Mexico to Philip IV. (1644) to stop the foundation of religious houses, which held half the property in the country, to suspend ordinances because there were 6000 unemployed priests, and to suppress feast days because they cost at least two per week.

To check the Dutch and British corsairs the Barlovento (“windward”) squadron had been set up in 1633; but the British capture of Jamaica (1655) aggravated the danger to the Spanish convoys. During the rest of the century the ports of Yucatán and Central America were frequently raided, and in 1682 Tampico suffered a like disaster; in May 1683 Vera Cruz itself was captured through stratagem by two buccaneers, Van Horn and Laurens, who plundered the town for ten days, committed shocking outrages, and escaped as the Spanish fleet arrived. In 1685-86 the Pacific coast was ravaged by Dampier and Swan, and in 1700 Woodes Rogers, with Dampier as pilot, captured the Manila treasure galleon, a feat repeated by Anson in 1743.

But the European wars of the 18th century had little effect on Mexico, save that the privileges of trade given to Great Britain by the treaty of Utrecht facilitated smuggling. In the first half of the 18th century we may note the appearance, intermittently at first, of the first Mexican periodical—the Gazeta de Mexico—in 1722, a severe epidemic of yellow fever in 1736, and the establishment about 1750 of a standing army with a nucleus of Walloons and Swiss, negroes and Indians being excluded and the half-breeds admitted under restrictions. But the great event of the 18th century was the expulsion of the Jesuits from Mexico, as from the other Spanish dominions, in 1767, under orders from Charles III. They were arrested en masse on the night of the 26th of June; their goods were sequestered, and they themselves deported to Havana, then to Cadiz, Genoa, and eventually Corsica. They had done much to civilize the natives and to educate the whites, and their expulsion, which was greatly resented by the Creoles, probably tended to increase the popular discontent and prepare for the overthrow of Spanish rule.

In 1769 Don José de Galvez was sent out as special commissioner to devise reforms, with powers independent of the then viceroy, but without much immediate result. It was, however, a consequence of his work that in 1786 the provinces and kingdoms were replaced by twelve intendencias (Guadalajara, Zacatecas, Durango, Sonora, Puebla, Vera Cruz, Merida, Oaxaca, Valladolid, Guanajuato, San Luis Potosí, Mexico), whose governors and minor officials were directly dependent on the vicerey, the former alcalde, mayors and corregidores, who were very corrupt, being abolished. Possibly it is from this reform that we may date the antithesis of the 18th century. The expulsion of the Jesuits was a victory of republican Mexico. Among the later viceroys the Conde de Revillagigedo (1789-1794) deserves mention as a progressive ruler who developed commerce and improved administration, and took the first, but very imperfect, census, on which Humboldt based his estimate of the population in 1803 at 5,840,000.

The European wars of the French Revolutionary period interfered with the traffic with Spain, and so relaxed the bonds of a commercial system which hampered the manufactures of Mexico and drained away its wealth. Already in 1783 the Conde de Aranda had suggested to the Spanish king the scheme of setting up three Spanish-American kingdoms bound to Spain by perpetual treaties of alliance and reciprocity and by frequent royal intermarriages, and with the king of Spain as overlord. The plan was devised as a means of ridding Anglo-Saxon supremacy, but was rejected through fear of the mixed races predominating over the whites. A similar fear helped to keep down the tendencies inspired by French revolutionary literature, though plots occurred against the viceroys Branciforte in 1798 and 1799. But the real causes of the revolution were local. The chief was the Creole jealousy of the Spanish immorality and brutality, the restriction on commerce and manufacture in the interest of Spain, even vineyards having been prohibited; and the courts were very corrupt. But to these grievances was added in 1804 the sequestration, to provide for Spain's needs, of the benevolent funds (obras pías) in Mexico, amounting to about $45,000,000, and nearly all invested on mortgage. The mortgages were called in: forced sales were necessary, the mortgagees were frequently ruined, and less than a fourth of the total was realized. Other confiscations and exactions followed; and when the rule of Ferdinand VII. was succeeded by Isabella's, the municipality of Mexico invited Iturrigaray, the vicerey, to declare the country independent. He proposed the convocation of a national congress, but was overthrown by a conspiracy of Spaniards under one Yermo, who feared that they would lose their privileged position through secession from Spain. The two next viceroys were incompetent; further demands from the Spanish authorities in revolt against Joseph Bonaparte increased the dissatisfaction, which was not allayed by the grant of representation in the Spanish Cortes to the colonies; and, on the demands being repeated by a third vicerey, Lafayette, the grievances arose in Querétaro and Guanajuato. Their discovery in 1810 was followed by the outbreak of the revolution. Hidalgo, a parish priest, and Allende, a captain of cavalry, with forces
consisting largely of Indians, captured a stronghold at Guanajato and even threatened the capital; but the revolutionists were defeated in 1811 at Calderón, and the leaders executed. Another priest, however, named Morales, continued the movement, and, despite defeat in the terrible siege of Cuautla (now Morelos) on the 2nd of May 1812, raised the south, so that in the next year his forces overran most of the kingdom of Mexico and held its southern parts, and he was able to invoke a congress and issue a constitution. But he also was captured, and executed at Mexico City in 1814. Though revolutionary sentiment still continued, by 1817 only one leader, Vicente Guerrero, was left in the field. But in March 1820 the Spanish constitution, repudiated by King Fernando VII. soon after his restoration, was restored after a military rising in Spain. It was promulgated in Mexico, and the ecclesiastics and Spaniards, fearing that a Liberal Spanish government would force on them disenchantment, toleration and other changes, induced Augustin de Iturbide, who had already been conspicuous in suppressing the risings, to take the field in order to effect what may be called a reactionary revolution.

III.—Independent Mexico.

Thenceforward, till the second election of Porfirio Díaz to the presidency in 1884, the history of Mexico is one of almost continuous warfare, in which Maximilian’s empire is a mere episode. The conflicts, which may at first sight seem to be merely between rival generals, are seen upon closer examination to be mainly (1) between the privileged classes, i.e. the church (as then the army), and the mass of the other civilized population; (2) between Centralists and Federalists, the former being identical with the army, the church and the supporters of despotism, while the latter represent the desire for republicanism and local self-government. Similar conflicts are exhibited, though less continuously, by most of the other Spanish-American states. On both sides in Mexico there was an element consisting of honest doctrinaires; but rival military leaders exploited the struggles in their own interest, sometimes taking each side successively; and the instability was intensified by the extreme poverty of the peasantry, which made the soldiery reluctant to return to civil life, by the absence of a regular middle class, and by the concentration of wealth in a few hands, so that a revolutionary chief was generally sure both of money and of men. But after 1884, under the rule of Diaz, the Federal system continued in name, but it concealed in fact, with great benefit to the nation, a highly centralized administration, very intelligent, and on the whole both popular and successful—a modern form of rational despotism.

Iturbide eventually combined with Guerrero, and proclaimed the “Plan of Iguala” in July 1822. The plan was laid down, as the bases of the new state, the maintenance of the Roman Catholic religion and the privileges of the clergy, the establishment of a limited monarchy, and equality of rights for Spaniards and native-born Mexicans. Iturbide sought the co-operation of the viceroy Apodaca, who, however, refused; but he was presently superseded by General O’Donojó, who, being unable to get beyond Vera Cruz, recognized the independence of Mexico. O’Donojó shortly afterwards died; the Spanish government repudiated his act; and Spanish troops held the fortress of San Juan de Ulúa, off Vera Cruz, till 1827. A provisional Junta, nominated by Iturbide, issued a declaration of independence (Oct. 1821), and nominated a regency of five, with Iturbide as its president. The first Mexican Congress met on the 24th of February 1822. A section of it favoured a republic; another, monarchy under Iturbide; another, which was broken up by the refusal of Spain (continued until 1836) to recognize Mexican independence, monarchy under a Bourbon prince. A conflict now arose between the republican majority and Iturbide, which was settled by a military pronouncement in his favour, and the Congress elected him emperor. He was crowned on the 9th of July 1822. Fresh conflicts broke out between him and the Congress, and Antonio Lopez de Santa Anna, captain-general of Vera Cruz, proclaimed, promising to support the Plan of Iguala. He was defeated at Jalapa and driven to Vera Cruz; but the army deserted Iturbide, who was compelled to abdicate (April 19, 1823). The Congress deported him to Italy, and granted him a pension. He returned almost immediately, on the pretext that Spain was intriguing against Mexican independence, and on landing (having been previously outlawed) was arrested and executed (July 1, 1824).

The Congress had meanwhile undone much of his work, and had divided into Federalists and Centralists, the latter largely Monarchists and Freemasons. The Federalists were strong enough to secure the adoption of a constitution (Oct. 4, 1824) modelled on that of the United States, with additional clauses, notably one declaring the Roman Catholic religion to be alone recognized. A source of abundant discord was opened by the provision that each state should contribute its quota to the Federal revenues. No proper statistical basis for estimating the quotas existed, and the device gave each state a plausible reason for attempting secession on occasion. Moreover, the capital and some territory round it was made into a “Federal district”—another grievance intensifying the antagonism of the state to the central power. The Freemasons had been largely instrumental in overthrowing Iturbide; they now divided into the Escoceses (lodges of the Scottish ritual), who were Monarchist and Centralist, and the Yorkinos, who took their ritual from New York, and their cue, it was alleged, from the American minister, Joel Poinsett. An attempt at revolt, headed by Nicolas Bravo, vice-president, the Grand Master of the Escoceses, was speedily suppressed, but dissensions ensued in the Yorkino party between the followers of President Guerrero (a man largely of native blood, and the last of the revolutionary leaders) and of Gomez Pedraza, the war minister. A conflict broke out, the Guerrist leaders were victorious, and the pillage of foreign ships in Mexico City (1828), among them that of a French baker, gave a basis for the foreign claims which, ten years later, caused the “Pastry War” with France. Meanwhile, attacks on Spanish ships off Cuba by a Mexican squadron, commanded by an American, David Porter, had induced Spain to send an expedition to reconquer Mexico (1829) which was checked at Tampico by Santa Anna. During the invasion Vice-President Antonio Bustamante declared against President Guerrero; the bulk of the army supported him. Guerrero was deposed, and his partisans in the south were defeated at Chilpancingo (Jan. 2, 1831); and Guerrero, retiring to Acapulco, was enticed on board an Italian merchant-ship, and treacherously seized, tried and executed (Jan.–Feb. 1831). Next year, however, a revolt broke out against Bustamante, which was joined by Santa Anna, and was speedily put down, but dissensions ensued in favour of Gomez Pedraza. He, and his successor, Vice-President Gomez Farias (1833), assailed the exemption of the clergy and of military officers from the jurisdiction of the civil courts, and the latter attempted to legalize higher education and to relax monastic bonds. Santa Anna took advantage of the situation to assume the presidency. He eventually became dictator, dissolved Congress (May 31, 1834) and the Dictator, in state legislatures, and substituted creatures of his own for the governors of the states and mayors of towns, then retiring into private life. A new Congress, having resolved to hold a constitutional assembly, followed up this Centralist policy (Dec. 30, 1836) by framing a new constitution, the Siete Leyes or Seven Laws, which converted the states into departments, ruled by governors appointed by the central authority, and considerably reduced popular representation. Antonio Bustamante became the first president under it. The French claims set up by the pillage of foreign President and shops in Mexico had, however, remained unsatisfied, and in 1838 a French fleet blockaded the coast, bombarded the fortress of San Juan de Ulúa, occupied the town of Vera Cruz, and the Mexican government gave way, threatened by Federalist risings and secessions of states, which culminated in 1841. Santa Anna appeared, nominally as a
mediator, and put forward the bases of tacubaya (Sept. 29, 1841), abolishing all the siete leyes except the part relating to the judicial system, arranging for a new constituent assembly, and preserving, for the present, full power of re-organizing the administration. The Centralist government, after a vain attempt to defeat him by professing a more thorough Federalism, gave way to force, and bustamante was allowed to leave the country. But the new Congress was too Federalist for santa anna, and he retired, leaving the reins to nicolas Bravo, under whom a new centralist constitution was established (1843). This expressly retained the privileges of the clergy and army, and was in some respects more anti-liberal than that of 1836. But new complications were now introduced by the question of Texas. Though a state of the Mexican Union, it had been settled from the United States in consequence of a land grant given by the Spanish viceroy to Stephen Austin in 1820, and had been estranged from Mexico partly by the abolition of slavery under a decree of President Guerrero, and partly by the prospect of the Centralist constitution of 1836. It then seemed santa anna attempted to reduce it, showing great severity, but was eventually defeated and captured by Houston at the battle of San Jacinto, and forced to sign a treaty recognizing Texas independence, which was disavowed on his return to Mexico. A state of war thus continued nominally between Mexico and its seceded member, whose independence was recognized by England, France and the United States. The slaveholders in the United States favoured annexation of Texas, and pressed the claims due from Mexico to American citizens, partly perhaps with the aim of forcing war. Most of these claims were settled by a mixed commission, with the King of Prussia as umpire, in 1840-1841, and a forced loan was raised to pay them in 1843, which stimulated the revolt of Paredes against Santa Anna, who had returned to power in 1843. It resulted in Santa Anna's downfall, imprisonment at Perote and eventual exile (Dec. 1844 to Jan. 1845), and the election of general jóse joaquin herrera as president. But herrera was displaced in the last days of 1845 by a pronunciamiento in favour of Paredes, who undertook to uphold the national rights against the United States, and who was elected president on the 3rd of January 1846. Texas had meanwhile applied for admission into the American union. the annexation, rejected in 1842 by the United States Senate, was sanctioned on the 1st of March 1845, and carried out on the 22nd of December 1845. The Mexican minister withdrew from Washington, and both sides made active preparations for war.

The United States forces were ordered by President Polk to advance to the Rio Grande in January 1846. They established a depot at Point Ysabel (behind the opening of brazos santiago), and erected a fort in texas territory, commanding Matamoros, on the Mexican side of the Rio Grande. This provoked the Mexican forces into a defensive invasion of Texas, to cut the American communications with point Ysabel. They were, however, defeated at Palo Alto (May 8) and Resaca de la Palma (May 9). There was an outburst of warlike feeling in the United States (with a counter-movement in the North), and an invasion of Mexico was planned by three routes—from Matamoros towards Monterey in new leon, from San Antonio de Bexar to Chihuahua, and from Fort Leavenworth to New Mexico. Importance attaches chiefly to the movements of the first force under general Zachary Taylor. During the war preparations president Paredes, suspected of intriguing to overthrow the Republican government, was set a Spanish prince, had to give place to his vice-president Bravo, who in turn gave way before Santa Anna, who was hastily recalled from his exile at Havana to assume the presidency and the conduct of the war (Aug. 1846). He was allowed by the American squadron blockading Vera Cruz to pass in without hindrance. Probably it was thought his presence would divide the Mexicans.

The preparations of the United States took some months. It was not till the 5th of September 1846 that General Zachary Taylor could leave his depot at Camargo on the Rio Grande, and march on Monterrey. It was taken by assault on the 23rd of September; Santa Anna was defeated at Buena Vista (near Saltillo) on the 23rd of February 1847, and forced back on San Luis Potosí. New Mexico was occupied without opposition; Chihuahua was occupied, but not held, owing to the difficulties in maintaining Communications; and Upper California was seized in the autumn of 1846 by John C. Fremont, who had been exploring a route across the continent, and by the United States Pacific squadron, and made secure by the aid of the New Mexico expedition. But as Mexico still continued to fight, it was determined to reach the capital via Vera Cruz. President Polk rejected General Geyn's scheme of a land expedition (March 7 to 29, 1847); and after winning the battle of Cerro Gordo (April 18), and a long delay at Puebla, Scott marched on Mexico city, stormed its defences against greatly superior forces, and effected an entrance after severe fighting on the 13th of September 1847. This virtually ended the war; Santa Anna was deprived of his command, and the treaty of Guadalupe Hidalgo, concluded on the 2nd of February 1848, ceded to the United States Texas, New Mexico and Upper California, in return for a payment of $15,000,000, by the United States to Mexico, and for substitution of liability by it for the claims of its subjects which it had hitherto been pressing against Mexico. This payment was doubtless intended to strengthen the United States' title to the conquered territory. It is generally admitted that Mexico was provoked into aggression in order that additional territory might be available for the extension of slavery.

The American forces were withdrawn in May and June 1848 after the ratification of the treaty by Mexico. Under the presidency of herrera (1848-1851) attempts were made to restore order and the public credit. An arrangement was effected with English holders of Mexican stock; a loan of $2,500,000 was taken from the United States to Mexico, and the Mexican government was to pay $500,000 annually to the United States citizens, who had lost money in consequence of the Mexican war.

After a sort of interregnum (Jan.-March 1853) Santa Anna was recalled (by a vote of the majority of the states under the plan of Arroyoarco, on the 4th of February 1853, the result Santa Anna in Power, 1853-1854). He was supported by a conservative and was succeeded by another of the same faction under his name. He was more energetic and was more successful in his measures, partly inspired by an able conservative leader, lucas alaman, proved strongly centralist: one is especially noteworthy, the establishment of the ministry of "fomento," or encouragement to public works, education, and intellectual and economic development, which is a conspicuous aid to Mexican welfare to-day. He also negotiated (at the end of 1853) the sale of the mexia valley (now Arizona) to the United States, but the purchase money was soon dissipated. On the 16th of December 1853 Santa Anna issued a decree making himself dictator, with the title of supreme highness. On the 1st of March 1854, at Ayutla in Guerrero, a section of the army under colonel villarreal proclaimed the Plan of Ayutla, demanding Santa Anna's deposition and the establishment of a provisional government to secure a new constitution. Among the leaders in the movement were Generals Alvarez and Comonfort, and it is said that forthright vista, his frequent successor, then a young soldier, made his way to Benito Juarez, then in prison, and arranged with him the preliminaries of the revolt. It spread, and Santa Anna left the country (Aug. 1854).1 Two filibustering expeditions at this time—one by william Walker, afterwards notorious in Nicaragua, in lower California 1 Santa Anna tried to get back to politics in Mexico after Maximilian's fall, without success. He was amnestied with other exiles in 1874, and died in obscurity in 1876.
MEXICO

(Mexico War, the) other by Count Raouset de Boulbon in Sonora (July 1854)—added to the general disorder.

The provisional president, General Carrera, proving too Centralist, was replaced by Alvarez (Sept. 24, 1855), two of whose ministers are conspicuous in later history—Ignacio Comonfort, minister of war, and Benito Juarez, minister of finance, and killed in battle, shot with a Mexican sabre. The son of a Zapotec peasant in a mountain village of Oaxaca, he was employed as a lad by a bookbinder in Oaxaca city, and aided by him to study for the priesthood. He soon turned to the law, though for a time he was teacher of physics in a small local college; eventually went into politics, and did excellent work in 1847 as governor of his native state. Juarez almost immediately secured the enactment of a law (Ley Juarez, Nov. 23, 1855) subjecting the clergy and the army to the Jurisdiction of the ordinary courts. Benefit of clergy was the curse of Mexico. Officers and soldiers could be tried only by courts-martial, the clergy (including numbers of persons in minor orders, who were practically laymen) only by ecclesiastical courts. The proposed reform roused the Clericals to resistance. Alvarez gave place (Dec. 8, 1855) to his war minister Comonfort, who represented the less anti-Clerical Liberals. He appointed a commission to consider the question of draining the valley of Mexico, which adopted the plan ultimately carried out in 1890-1900; suppressed a Clerical rising in Puebla (March 1856), which was punished by a considerable confiscation of church property; sanctioned a law releasing church land from mortmain, by providing for its sale, for the benefit, however, of the ecclesiastical owners (called after his author Miguel Lerdo de Tejada, brother of the subsequent president), and a new draft constitution, largely modelled on that of the United States (Feb. 5, 1857).

The clergy protested violently, and the Plan of Tacubaya (Dec. 17, 1857), which made Comonfort dictator, provided for the construction of a new constitution under his auspices. He was presently displaced by a thorough reactionary, General Zuloaga, and expelled from Mexico early in 1858; and for three years Mexico was a prey to civil war between two rival governments— the Republicans at Vera Cruz under Juarez, who, as Chief Justice of the Supreme Court, succeeded Comonfort; and the reactionaries at the capital. The latter were at first presided over by Zuloaga, who, proving incompetent, was replaced at the end of 1858 by Pefuca, who early in 1859 gave place to Miguel Miramon, a young, able and unscrupulous soldier who was shortly afterwards accepted as "constitutitive" president by his party. The Jurists were defeated outside the city of Mexico twice, in October 1858 and on the 11th of April, 1859.

On the second occasion the whole body of officers, responding to Miramon's command, began to exalt him to the authority, if not by his express orders, together with several surgeons (including one Englishman, Du Valu) (the fifty-three "martyrs of Tacubaya"). This atrocity caused great indignation in Mexico and abroad; the reactionists were divided; their financial straits were extreme, as the Jurists held all the chief ports. Juarez was recognized by the United States, and allowed to draw supplies of arms and volunteers thence; and in July 1859 he published laws suppressing the religious orders, nationalizing ecclesiastical property (of the estimated value of $45,000,000), establishing civil marriage, registeration, transferring the cemeteries to civil control, and, in short, disestablishing the church. But the apparent hopelessness of any ending to the conflict, together with the frequent outrages of both parties on foreigners, afforded strong reasons for foreign intervention. Early in 1859 President Buchanan had recommended the step to Congress, which did not respond. On the 12th of December 1859 the M'Lean-Juarez treaty was concluded, which gave the United States a sort of disguised protectorate over Mexico, with certain rights of way for railroads over the Isthmus of Tehuantepac and between the Rio Grande and Pacific. The American minister, however, was unwilling to ratify the treaty, and a motion for its reconsideration late in 1860 came to nothing, owing to the approach of the War of Secession.

When Napoleon III. was in captivity at Ham he dreamed of a Central America civilized and opened up to modern enterprise by a transoceanic canal; and the clerical refugees in Paris, among them Labastida, archbishop of Mexico, easily influenced the Empress Eugenie, herself a Spaniard, to interest her husband in the cause of centralized monarchy and the church: it is said that even in 1859 they had thoughts of setting up the Archduke Maximilian as ruler of Mexico.

The question of a joint intervention of Great Britain, France, Spain and Prussia was mooted between those powers in 1860. Early in 1859 the outrages on British subjects had caused the British minister to break off diplomatic relations. Forced contributions had been levied by 1860, both sides on goods or bullion, being European property, the reactionaries being the worst offenders; and there were numerous cases of murder and robbery of Europeans. At last, on the 17th of November 1860, Miramon, under the plea of necessity, seized $80,000 in specie which had been left under seal at the British Legation and was intended for the bondholders. On the 22nd of December 1860 his forces were routed by the Jurist general Ortega at Arroyozarco, and his government was overthrown.

Juarez entered Mexico City on the 11th of January 1861. He soon found that his government was held responsible to Europe for the excesses of its rival as well as its own. Miramon's government had violated the British Legation; the Spanish minister, the papal legate and the representatives of Guatemala and Columbia were expelled from the country for undue interference on behalf of the reactionaries; the payments of the British loan were suspended by Juarez's Congress in July 1861; and various outrages had been committed on the persons and property of Europeans for which no redress could be obtained. The French chargé d'affaires, Dubois de Saligny, who had been sent out in November 1860, urged French intervention, and took up the Jecker claims. Jecker, a Swiss banker settled in Mexico, had lent Miramon's government in 1859 $750,000 (subject, however, to various deductions): in return, Miramon gave him 6% bonds of the nominal value of $15,000,000 which were ingeniously disguised as a conversion scheme. Jecker had failed early in 1860, Miramon was overthrown a few months later. Jecker's creditors were mostly French, but he still held most of the bonds, and there is reason to believe that he won over Dubois de Saligny by corrupt means to support his claims. Intercepted correspondence (since confirmed from the archives of the Tuileries) showed that the Duc de Morny promised Jecker his patronage in return for 30% of the profits (De la Gorce, Hist. du Second Empire, IV. c. I). An imperial decree naturalized Jecker in France, and Napoleon III. took up his claim. A convention between Great Britain, France and Spain for joint interference in Mexico was signed in London on the 31st of October 1861. A separate arrangement of the British claims was negotiated by Juarez, but rejected by the Mexican Congress, November 1861; and the assistance of the United States with a small loan was declined, Mexican territory being demanded as security. On the 14th of December Vera Cruz was occupied by Spanish troops under General Prim; the French fleet and troops arrived soon after, with instructions to seize and hold the Gulf ports and collect the customs for the three Powers till the British were paid. The British were repulsed from Vera Cruz, and left, save only 700 marines. In view of the unhealthiness of Vera Cruz, the convention of Soledad was concluded with the Mexican government, permitting the foreign troops to advance to Oriaba and incidentally recognizing Mexican independence. But as the French harboured leaders of the Mexican reactionaries, pressed the Jecker claims and showed a disposition to interfere in Mexican domestic politics, which lay beyond the terms of the joint convention, Great Britain and Spain withdrew their forces in March 1862.

More troops were sent from France. Their advance was checked by Zaragoza and Porfirio Diaz in the battle of Cinco de Mayo, on the 5th of May 1862; and in September of that year 30,000 more French troops arrived under General Forey. Wintering at Oriaba, they recommended their advance
MEXICO

(INDEPENDENT MEXICO)

(Feb. 17, 1863), besieged and reduced Puebla, and entered Mexico City on the 7th of June. A provisional government of Mexicans, nominated directly or indirectly by Dubois de Escobar, Solis, an adopted monarchy, offered the crown to Maximilian of Austria, brother of the Emperor Francis Joseph, and should he refuse, left its disposal to Napoleon III.

Maximilian, after some difficulty as to renouncing his right of succession to the throne of Austria, accepted the crown, Maximilian subject to the approval of the Mexican people, and the Emperor, Emperor, had reached Mexico city on the 12th of June 1864. Juarez meanwhile had set up his capital, first in San Luis, then in Potosi, then in Chihuahua. The new empire was unsanctioned from the first. Before Maximilian arrived the provisional government had refused to cancel the sales of confiscated Church lands, as the clericals demanded. When he came, a host of new difficulties arose. A new loan, nominally of about eight millions sterling, but yielding little more than four, owing to discount and commission, was raised in Europe, but no funds were really available for its service. Maximilian carried the elaborate etiquette of the court of Vienna to Mexico, but favouring toleration of Protestantism, and the suppression of the clericals in the Church, he was too liberal for the clericals who had set him up. As a foreigner he was unpopular, and the regiments of Austrians and Belgians which were to serve as the nucleus of his own army were more so. His reforms, excellent on paper, could not be carried out, for the trained bureaucracy necessary did not exist. For a time he nominally held sway over about two-thirds of the country—roughly, from lat. 18° to 23°, thus excluding the extreme north and south. Oaxaca city, under Porfirio Diaz, capitulated to Bazaine—who had superseded the too pro-clerical Forey in October 1864—its February 1865, and by the autumn of that year the condition of the Juarists in the north seemed desperate. But the towns asked for permanent French garrisons, which were refused, as weakening their own power of self-defense. Instead, the country was traversed by flying columns, and the guerrillas dealt with by a French service of "contre-guerrillas," who fought with much the same savagery as their foes. Directly the French troops had passed, Republican bands sprang up, and the non-combatant Mexicans, to save themselves, could only profess neutrality. Yet on the 3rd of October 1865, Maximilian, misled by a false report that Juarez had left the country, issued a decree declaring the Juarists guerrillas, who, whenever captured, were to be tried by court-martial and shot. Mexican generals on both sides had done as much. But Maximilian's decree prepared his own fate.

The American Civil War ended in the spring of 1865, and a strong popular feeling was at once manifested in favour of asserting the Monroe doctrine against Maximilian's government. In the summer there were threatening movements of United States troops towards the Rio Grande; early in 1866 Maximilian despatched by Napoleon III. announced his intention of withdrawing France. his forces; in response to a note of Seward, the United States secretary of state, of the 12th of February 1866, he was induced to promise their return by three instalments—in November 1866, March and November 1867. Maximilian now turned for support to the Mexican clericals; mediated abdication, but was dissuaded by his wife Charlotte, the daughter of Leopold I. of Belgium (and "the better man of the two," as he had once jestingly said), who went to intercede for him with the emperor of the French. Finding him obdurate, she went on to appeal to the pope; while at Rome she went mad (end of September 1866).

Maximilian had meanwhile drawn nearer to the clericals and farther from the French, and, to protect French interests, Napoleon III. had decided to send out General Castelnau to supersede Bazaine, arrange for the withdrawal of the French forces in one body, and restore the Republic under Ortega, who had quarrelled with Juarez, and was therefore, of all republicans, least acceptable to the clericals. But fearing the prospect, they induced Maximilian, who had recoiled to Orizaba for his health, to remain. He yielded on condition that a congress of all parties should be summoned to decide the fate of the empire. Hereupon he returned to the capital; the Juarist dominion extended rapidly; the French troops left (in one body) on the 5th of February 1867, and shortly after Maximilian took command of the army at Queretaro. Here, with Miramon, he was besieged by the Juarists under Escobedo, and the garrison, when about to make a last attempt to break out, was betrayed by Colonel Lopez to the besiegers (May 15, 1867).

Execution of Maximilian, with the Mexican general, was tried by court-martial, and, refusing (or neglecting) to avail himself of various opportunities of escape, was convicted on charges which may be summarized as rebellion, murder and brigandage, on the 14th of June, and shot, with Miramon and Mejia, on the 19th of June 1867, despite many protests from European governments and prominent individuals, including Garibaldi and Victor Hugo. (An effort to save him made by the U.S. Government was frustrated by the dilatoriness of the U.S. Minister accredited to Juarez's Government.) After considerable difficulty, and the Republican Government, his body was brought to Europe.

Meanwhile Porfirio Diaz had captured Puebla (April 2) and besieged Mexico City, which fell on the 21st of June. The last anti-Juarez stronghold (Inyaryit) submitted on the 20th of July 1867. A good deal of discontent existed among the republican rank and file, and Juarez's election in October to the presidency was opposed by Diaz's friends, but without success. But so soon as Juarez was elected, insurrections broke out, and brigandage prevailed throughout the following year. The first four unsuccessful insurrections also in 1866 (cultural) and 1870 (republican), but an amnesty, passed on the 13th of October 1870, helped to restore peace; trouble again arose, however, at the 1871 election, at which the candidates were Juarez, Sebastian Lerdo de Tejada and Diaz. Juarez's continued re-election was regarded as unconstitutional, and no party obtaining a clear majority, the matter was thrown into Congress, which elected him. Diaz's supporters refused to recognize him, and a revolution broke out, which went on sporadically till Juarez's death on the 18th of July 1872, Sebastian Lerdo de Tejada, as president of the Supreme Court, succeeded him, and annexed the rebels, but made no further concessions. In the next year, however, laws were passed repeating in a stronger form the attacks of 1857 on the supremacy of the Church, and prohibiting monastic life. The first day of 1873 was marked by the opening of the Vera Cruz & Mexico railway. Protestant missions established themselves (with some opposition) in the country, and diplomatic relations were renewed with France and Spain (1874). But towards the close of Lerdo de Tejada's term he was suspected of aiming at a dictatorship, and Diaz, whom he had proscribed, made preparations for a rising, then retiring to Texas. At the beginning of 1876 the revolution broke out in Oaxaca with the plan of Tuxtepec, which was adopted by Diaz, and proclaimed as the plan of Palo Blanco (March 21). Diaz's attempt to raise the north, however, failed, and, trying to reach Vera Cruz by sea, he was recognized on the steamer, and recaptured while attempting a four-mile swim ashore. The purser, however, made it appear that he had again jumped overboard, concealed him for some days—generally inside one of the saloon sofas—and helped him to get ashore in disguise at Vera Cruz. He then escaped to Oaxaca and was declared re-elected, but was overthrown by Diaz after the battle of Tecoeac (Nov. 16, 1876) and forced into exile (Jan. 1877), and Diaz was declared president on the 2nd of May 1877. A law forbidding the re-election of a president till four years had elapsed from his retirement from office was passed in the autumn of that year.

1 Lopez said he acted as Maximilian's agent, but his story rested on an alleged letter from Maximilian which was discredited as a forgery. The evidence of his treason was published in El Nacional of Mexico, Sept. 11, 1887.
Díaz's first presidency (1876–1880) was marked by some unsuccessful attempts at revolution notably by Escobedo from Texas in 1878, and by a more serious conspiracy in 1879. Diplomatic relations were resumed with Spain, Germany, Italy, and some South American states (1877), and France (1880). The territory against frontier claimants in the United States, and with Guatemala, which revived a claim dropped since 1858 to a portion of the state of Chiapas; and there was considerable internal unrest, aided by a too liberal policy of subsidies to railways and even to lines of steamships. The boundary questions were settled under President González (1880–1884); relations with Great Britain were renewed in 1884. The claims of the railways, however, necessitated retrenchment on official salaries, and the president's plan for, conversion of the debt aroused unexpected and successful opposition in an ordinarily subservient Congress. At the end of 1884 Porfirio Díaz was again elected president, and was continually re-elected, the constitution being modified expressly to allow him to continue in office.

The history of Mexico from 1884 to 1910 was almost void of political strife. President Díaz's policy was to keep down disorder with a strong hand; to enforce the law; to foster railway development and economic progress; to develop native manufactures by protective tariffs; to introduce new industries, e.g. the production of silk and wine, of coca and quinine; to promote forestry; to improve elementary and higher education—for all which purposes the Ministerio del Fomento was a potent engine; to encourage colonization; and, above all, to place the national credit on a sound basis. The first step in this process was a settlement of the British debt by direct arrangement with the bondholders. In 1890 the Spanish bondholders' claims were satisfactorily arranged also. In 1891 the tariff was made more protectionist. In 1893 the depreciation of silver necessitated stringent retrenchment; but the budget balanced for the first time during many years, the floating debt was converted, and a loan raised for the completion of the Tehuantepec Railway. After 1896 substantial annual surpluses were spent in reducing taxation and in the extinction of debt. In 1895 the 6% external debt was converted into a 5% debt, the bonds of which remained at a premium for 1922; in 1896 the alcabalas or interstate customs and municipal octrois were abolished, and replaced in part by direct taxation and increased stamp duties.

The institution by Diaz of the guardias rurales, a mounted gendarmerie composed of the class who in former days drifted to the southern provinces, and were known as the _Pacification into revolution and brigandage, was a potent means of the Country._ To these ends, telegraph lines and telegraphs enabled the government to cope at once with any disturbance. The old local revolutions practically disappeared. In 1886–1887 there were some disturbances in Coahuila, New Leon, Sinaloa and Tamaulipas; subsequently hardly anything was heard of such disorders except on the Texan frontier, where in 1890 Francisco Ruiz Sandoval and in 1891 Catario Garza made incursions into Mexico. Occasionally the Church gave trouble—the presence of foreign priests was complained of; attempts to evade the law prohibiting conventual life were detected and foiled (1891, 1892); and the outbreaks and rising, represented sometimes with great severity, among the Mayas of Yucatán, whose last stronghold was taken in 1891, and the Ayquis of Sonora (1890–1900). Under federal and democratic forms, Diaz exercised a strictly centralized and personal rule. He was invited to approve the candidates proposed for state governorships; in all law cases affecting the Government or political matters the judges asked his opinion; he drafted bills, and discussed their text with individual members and committees of congress. Similarly, the state legislatures, as well as the judges and municipal officers, were actually or virtually selected by the state governors, who were practically agents of the president. Now and then the old passions broke out: in September 1898 an abortive attempt to assassinate President Díaz was made by a countryman named Arroyo, but discontent with Díaz's rule was apparently confined to a small minority. In 1900 indeed there were some disquieting symptoms. Owing to Diaz's age the vice-presidency had been revived in 1904, and Don Ramón Corral elected to it; but at the elections of 1909 a movement arose in favour of replacing him by General Bernardo Reyes, Governor of Nuevo Leon, but he was eliminated by Diaz, and in taking out the surplus was given military systems of Europe. It was, therefore, regarded as certain that, should President Diaz die in office, Señor Corral would succeed him without serious difficulty.

In foreign affairs the rule of Diaz was uneventful. There were transient disputes with the United States (1886, 1888). In 1888–1890 and 1894–1895 a boundary dispute with Guatemala became serious. But Guatemala gave way at the threat of war (Jan. 1895) and a new treaty was made (April 1, 1893). Again in 1897 there was some friction arising to the murder of a Guatemalan ex-president by a compatriot in Mexico: later in the year, however, the Mexican government was active in stopping a war between its Central American neighbours. In the difficulty between England and the United States over the Venezuelan boundary (Dec. 1895) Mexico expressed strong adherence to the Monroe doctrine in the abstract, and suggested that its maintenance should not be left wholly to the United States, but should be undertaken by all American Powers. The first Pan-American congress met in Mexico City in 1901, and the country was represented at the second, held in Rio Janeiro in 1906. Mexico also took part in establishing the permanent Central American Court of Arbitration, inaugurated on the 25th of May 1908 at Cartago, Costa Rica, under the Washington treaties of December 1907, and showed readiness to associate herself with the Government of her great northern neighbour in preserving peace among the Central American States. On the 17th of October 1909 President Tait and President Diaz exchanged visits at the frontier at El Paso, Texas.

In brief, under President Diaz's rule the history of Mexico is one of steady, though slow, progress. The six financial years 1893–1894 to 1899–1900 inclusive the yield of the import duties was increased by upwards of 86%; the revenue from stamps over 69%, though the duties were reduced; the postal revenue from 1895–1896 to 1899–1900 rose 66%; the telegraph revenue over 75%. Again, in 1888–1890 the total ordinary revenue of the state was $6,013,921; in 1906–1907 it had increased to $11,428,612, or by more than 80% and though 1907–1908 was a year of depression its total revenue ($14,177,180) exceeded that of any year save its immediate predecessor. The great drainage scheme which completed the work of the 17th centenary was undertaken at Vera Cruz, on the southern lakes of the valley of Mexico was devised in 1856, begun under Maximilian, proceeded with intermittently till 1885, then taken up with improved plans, practically completed by 1896, and inaugurated in 1906; the harbour of Vera Cruz was finished in 1922; the Tehuantepec railway, likely to prove a formidable rival to any interoceanic canal, was opened on the 24th of January 1906. All three were the work of an English firm of contractors, the head of which was Sir Weetman Pearson. American, and later Canadian, capital and enterprise have also been very largely concerned in the development of the country; and economic progress was not permanently interfered with by the great earthquakes of April 1907 and July 1909 at Acapulco, and the floods in August 1909 at Monterey. In 1891 elementary education was reorganized, and made compulsory, secular and gratuitous. Great attention has been paid to higher education, and—at least in the hospitals—to modern sanitation and hygiene.

---

1 Don Augustin Icurbide, grandson of the emperor, godson and (perhaps) at one time the destined heir of Maximilian, was turned out of the army and imprisoned in 1880 for abusing President Diaz.
Lake Xochimilco is celebrated for its "floating gardens" or chinampas (see Mexico, Federal District of). The principal industries of the state are agricultural, and the principal products are cereals, sugar, maguey (from which pulque is made), coffee, and fruit. Stock-raising has also had a profitable development, owing to the fertility of the national capital. The manufacturing industries are important; among the manufactures are cotton and woolen fabrics, flour, dairy products, glassware, pottery, bricks, wines and spirits. The making of "pulque" from the sap of the maguey plant (Agave americana) is the chief industry of the state, and the product is exported in large quantities to the national capital. The state is traversed by the Central, National, Mexican International and Interocceanic railways, and by short lines from the national capital to neighbouring towns. The capital is Toluca, and other important towns are: Toluca de Posco (pop. 5947 in 1900), 36 m. N. of the national capital, Tenango de Valle (5881 in 1900), 15 m. E. of Toluca, and Lerma (estimated, 7200), near the western frontier of the state.

MEXICO, a city and the county-seat of Audrain county, Missouri, U.S.A., N.E. of the centre of the state, and about 110 m. N.W. of St Louis. Pop. (1890), 4789; (1900), 5099, including 948 negroes and 111 foreign-born; (1910), 5939. It is served by the Chicago & Alton, the Chicago, Burlington & Quincy, and the Wabash railway systems. Mexico is the seat of Hardin College and Conservatory of Music (1884), and of Wabash College (1900), an institution founded and endowed by Charles H. Hardin (1820-1862), governor of the state in 1872-1874, and of the Missouri Military Academy (1886). The city is situated in the blue grass region of Missouri, and is a shipping-point for horses and mules. Among the manufactures are flour, shoes, and fire-clay products. Mexico was laid out as "New Mexico" in 1836, and became the county-seat under its present name in 1837. It was incorporated as a town in 1855, was entered by the Wabash road in 1858 and by the Alton in 1872, and was first chartered as a city in 1878.

MEXICO CITY, the capital of the Republic of Mexico and chief town of the Federal District, near the southern margin of the great central plateau of Mexico, in lat. 16° 25' 45" N., long. 96° 7' W. It is about 200 m. in a direct line W. by N. of Vera Cruz, its nearest port on the Gulf of Mexico, with which it is connected by two railway lines, one of which is 264 m. long; and about 181 m. in a direct line N.N.E. of Acapulco, its nearest port on the Pacific, with which it is connected partly by rail and partly by a rough mountain trail (the camino real) to the coast. Pop. (1900), 344,721.

The city stands on a small plain occupying the south-western part of a large lacustrine depression known as the Valley of Mexico (El Valle de Mexico), about 3 m. from the western shore of Lake Texcoco, whose waters once covered a considerable part of the ground now occupied by the city. The Valley, including the drainage basin of Lake Zumpango, has an area of 2120 sq. m. (1627 sq. m. without that basin). The elevation of the city above sea-level is 7415 ft., only a few feet above the level of Lake Texcoco. The general elevation of the Valley is about 7300 ft., that of Lake Zumpango being 7493 ft., and of Lake Texcoco 7480 ft. The eastern shore of the transversal cordillera on the north and south sides— the Sierra de Guaudalupe (650 to 750 ft. above the city) on the north, and the Sierra Nevada with its snow-clad peaks of Popocatapelt and Ixtaccihuatl further away to the south-east— and by a part of the Sierra de Ajasco, known as the Montes de las Cruces, from which the greater part of the city's water supply is derived. Lake Texcoco (Texcoco or Texcoco) is a comparatively shallow body of brackish water, with an area of about 113 sq. m., and is fed by a number of small streams from the neighbouring mountains, and by the overflow of the others. Its shores are swampy and desolate and show considerable belts of saline incrustations with the fall in its level. The Aztecs settled there because of the security afforded by its islands and shallow waters—their city, Tenochtitlán, being so completely surrounded by water that a handful of warriors could easily

345

defend its approaches against a greatly superior force. The Chalco and Xochimilco lakes, 8 or 9 m. to the southward, which are separated by a narrow ridge of land, are connected with the lower part of the city by an artificial canal, called "La Viga," 16 m. long and so narrow that only one canoe at a time can pass out for the overflow of those lakes and as a waterway for the navigation of old boats, bringing in flowers and vegetables for sale. Lake Xochimilco, celebrated for its chinampas, or "floating gardens" (see MEXICO, FEDERAL DISTRICT OF), is supplied very largely by fresh-water springs opening within the lake, which the city has partially diverted for its own water supply. Lake Chalco is also greatly reduced in size by railway fillings and irrigation works, to the great distress of the natives who have gained their living by fishing in its waters since long before the Spanish conquest.

The climate of the city is temperate, dry and healthful. The temperature ranges from a minimum of 55° F. in winter to a maximum of 70° in summer. The winter range is 35° to 68°, and the summer so to 70°. The nights are always cool. The year is divided into a wet and dry season, the former from April to September, the latter from October to March. The rainfall, however, is light, about 20 to 25 in., but, with the assistance of irrigation, it serves to sustain a considerable degree of cultivation in the neighbourhood of the city. The health of the city, unfortunately, does not correspond with its favourable climatic conditions. With a wet, undrained subsoil and a large population of Indians and half-breeds living in crowded dwellings, the death rate has been notoriously high, though the completion of the Valley drainage works in 1900, supplemented by underground sewers in the better parts of the city, and by better sanitation, have recently improved matters. The annual death-rate per 1000 was 54 per 1000 for the Federal District in 1901, 50 in 1902, 45 in 1903, 46 in 1904, and 56 in 1905; the increase for the last-mentioned year being due to an epidemic of typhus fever.

The city is laid out with almost unbroken regularity and is compactly built—the streets running nearly with the cardinal points of the compass. The new and better residence sections are on the western side; the poorer districts are on the eastern side near the swampy shores of Lake Texcoco. As the name of a street changes with almost every block, according to the old Spanish custom, a list of street names is sometimes mistakenly accepted as the number of continuous thoroughfares in the city; so that it has been said that Mexico has 500 to 900 streets and alleys. An attempt was made in 1889 to rename the streets—all running east and west to be called avedas, all running north and south, with proper connections between thoroughfares to one name—but the people clung so tenaciously to the old names that the government was compelled to restore them in 1907. Outside the Indian districts of the eastern and southern outskirts, the streets are paved with asphalt and stone, lighted with electricity and gas, and served with an efficient street railway service. The political and commercial centre of the city is the Plaza Mayor, or Plaza de la Constitución, on which face the cathedral, national palace, and municipal palace. Grouped about the Plaza de Santo Domingo are the old convent and church of Santo Domingo, the court of the Inquisition now occupied by the School of Medicine, the offices of the Department of Communications, and the old custom-house (aduana). Close by are the old church of the Jesuits and the mechanics' school (artes y oficios) with its large and well-equipped shops. Among other well-known plazas are: Loreto, on which faces the great enclosed market of the city; Guadalupe, in the midst of hand-some private residences; San Fernando, with its statue of Vicente Guerrero; and Morelos, with its marble statue of the national hero of that name. The Paseo de la Reforma, the finest avenue of the city, is a broad boulevard extending from the Avenida Juárez south-west to Chapultepec, a distance of nearly three miles. At intervals are circular spaces, called "glorietas" with statues (the famous bronze equestrian statue of Charles IV., and monuments to Columbus, Cuauhtemoc the last of the Aztec emperors, and Juárez). Other notable avenues are Bucareli and Juárez, and the Avenida de la Viga, which skirts the canal of that name. The principal business streets runs westward from the Plaza Mayor toward the Alameda, and is known as the Calle de los Plateros (Silversmiths' Street) for two squares, Calle de San Francisco for three squares, and Avenida Juárez along the side south of the Alameda to its junction with the Paseo. The Alameda, or public garden, 1/2 m. west of the Plaza Mayor, covers an area of 40 acres, and occupies the site of the old Indian market and place of execution, where occurred the first auto-da-fé in Mexico in 1574.

The great cathedral stands on or near the site of the Aztec temple (teocalli) destroyed by Cortés in 1521. The foundations of the church were laid in 1537, the edifice was completed in 1545, the roof was finished in 1625, its consecration took place in 1642. In March 1667, the towers were completed in 1791, and the great church was finished about 1811. It is 426 ft. in length by 197 ft. wide, and its height from the floor of its lower nave is 114 ft. The general plan is that of a Greek cross, with two great nave aisles and three aisles, twenty side-chapels and a magnificent high altar supported by marble columns and crowned by a tumbaga balustrade with sixty-two tumbaga statues carrying chromite candles made from a rich alloy of gold, silver and copper. The elaborately carved choir is also enclosed by tumbaga railings made in Macao, weighing 26 tons. The vaulted roof is supported by twenty Doric columns, 180 ft. in height, and the whole interior is richly carved and gilded. The walls are covered with rare paintings. Standing close beside the cathedral is the highly ornamented façade of a smaller church called El Sagrado Metropolitano. The city contains much edifices, including La Profesa, Loreto, Santa Teresa, Santo Domingo and San Hipólito. At the time of the secularization of Church property, these became places of religious worship in the city, churches, convents, monasteries, etc.—many of which were turned over to secular uses.

The national palace, also on the Plaza Mayor, has a frontage of 66 ft. to the east of the Paseo de la Reforma, and covers a square of 47,800 sq. yds., or nearly 10 acres. It contains the executive offices of the government and those of five cabinet ministers (interior, foreign affairs, treasury, public works, and agriculture), the senate chamber, the general archives, national museum, observatory and meteorological bureau. The palace occupies the site of the residence of Moctezuma, which was destroyed by the Spaniards, and that of Hernando Cortés, which was also destroyed by the same. It is called the Palacio de la Plaza, and over its main gateway hangs the "liberty bell" of Mexico, first rung by the humble parish priest Hidalgo, on the night of the 16th of September 1810, to call the people of Dolores to arms, and now rung at midnight on each commemorating anniversary by the president himself. The national museum, which occupies the east side of the national palace, is rich in Mexican antiquities, among which are the famous "calendar stone," supposed to be of Toltec origin, and the "sacrificial stone" found in the ruins of the great teocalli destroyed by Cortés. Near the cathedral is the monte de piedad, or government pawnshop, endowed in 1775 by Pedro de Minoria, for the benefit of the poor. The bank is now carrying on a regular banking business including the issue of bank-notes. Its business is now limited to the issue of small loans on personal property which it aggregates; sometimes reaching nearly one million a month. The National Library of Mexico has 225,000 volumes, occupies the old St Augustine Church, dedicated in 1692 and devoted to its present use by Juárez in 1857. It is one of the most interesting public buildings in the city of Mexico. The academy of San Carlos and school of fine arts (founded in 1778) likewise contains good collections of paintings and statuary.

Among other institutions are the new post office, begun in 1902 and finished in 1907; the Mint, occupied by the schools of minting and engineering; the military school, occupying a part of the castle of Chapultepec; the Iturbide palace, now occupied as a hotel; the Iturbide theatre, occupied by the chamber of deputies, from which a new legislative palace to cost 2,500,000 pesos was under construction in 1909; the new palace of justice; the old mint, dating from 1537; the new penitentiary, completed in 1900; the Partón, the tomb of Ahuizotl, a great Aztec king, covered with a dome, a general hospital; the jockey club on Plaza Guadalupe, a new university (1910) and new school edifices of modern design. The city is likewise generously provided with hospitals and asylums.

The Spanish colonial sections were constructed of stone, and private residences were provided with iron gates and window guards strong enough to withstand an ordinary assault. Private houses were also provided with roofs of Tiles, not only to give them great defensive strength, as well as a cool, secluded retreat for their inmates in the evening. The old Moorish style of building about an open court, or patio, prevails, and the living-rooms, the family rooms on the ground floor, are usually the very drab appearance, but are less solidly built.

1 Bandelier thinks it should be called the "Stone of the Sun."
Mexico City

Mexico was formerly one of the worst drained large cities of the New World, its subsoil being permanently saturated and its artificial drainage being through open ditches into the San Lazaro Canal which was 14 ft. above sea-level. The lowest point in the city and the lake being less than six feet and the lake having no natural outlet, typhus fever became a common epidemic in its low and poor habitations. The first effort to improve this condition was made by the Dutch engineer Maertens (Span., Martine), who planned a deep cutting through Nochistongo Hill, north of the city, to carry away the overflow of Lake Zumpango (7493 ft. elevation), a tributary lake, a distance of 13 miles. The work was 13 m. long and is known as the Tajo de Nochistongo. It was begun in 1607—when the city was completely flooded—but was not completed until 1789, and then it was found that the city was watered by a spring which gives an output of money and 70,000 lives of Indian labourers had been expended upon it. The worst inundation in the history of the city occurred in 1789, when it was completely flooded. The water-works of the city remained flooded until 1834. In 1856 President Ignacio Comonfort invited tenders for drainage works conditional on the use of waste waters for irrigation purposes, and the plan executed consists of a canal and tunnel 43 m. long, starting from the east side and 43 ft. below the mean level of the city and running north to Zumpango and thence eastward into a tunnel over 6 m. long, which discharges into a small tributary of the Panuco near the town of Teixjiqueua. The greatest depth of the tunnel is 50 ft. below the surface. The works were inaugurated in 1900.

For the water supply the Aztecs used the main causeway through their capital Tenochtitlán, which was 13 m. above sea-level, into the brackish water of Texcoco, and obtained drinking water from a spring at the base of the hill of Chapultepec. The Spaniards added three other springs to the supply and constructed two long arched aqueducts between the towns. They were added during the 19th century, and in 1895-1906 steps were taken to secure a further supply from the Rio Hondo. Besides these there are 175 private artesian wells in the arroyo and its sources is estimated to yield about 220 to 230 litres per head.

Considerable attention has always been given to education in Mexico, but in colonial times it was limited in scope, and to the dominant classes. The old university of Mexico, with faculties of theology, law and medicine (?founded 1551 and inaugurated 1553), ceased to exist in 1865 and was succeeded by schools of engineering, law and medicine. There are also several scientific organizations and societies. The Mexican Geographical Society (Sociedad mexicana de Geografía e Historia) was founded in 1832. There are also the Geological Society, the Association of Engineers and Architects, the Mexican Society of Natural History.

Through lack of water-power resources, Mexico has never been rated as a manufacturing city. However, the development of electric power, and the possibility of transmitting it for long distances over Rosenberg-type synchronous machines, has led to the creation of many industries in this field, and a large number of industries have been added in recent years. The largest of these electric-power plants is on the Nechoa and Tenango rivers, in the state of Puebla, 92 m. from the city, which is designed to furnish 40,000 horse-power for industrial and lighting purposes. The last-mentioned power plant, which was completed in 1904, and a duplicate plant was decided upon in 1906. Another plant is in the suburb of San Lazaro, the current being distributed by overhead wires in its outskirts and suburbs. Other plants are at San Lázaro, 12 m. distant, and on the Churubusco river, 16 m. south. According to a British consular report for 1904 there were 139 establishments for the production of cotton manufactures. The products include linen, silk, cotton and linen textiles, leather, boots and shoes, alcohol and alcoholic beverages, beer, flour, conserves and candied fruits, spices and cacao, chocolate, matches, hats, oils, ice, furniture, pianos and other musical instruments, matches, beds, pianos, chemicals, iron and steel, printing-type, paint and varnish, glass, looking-glass, cement and artificial stone, earthenware, bricks and tiles, curio and ivory goods, saddles, saddles for horses, white lead, perfumery, carriages and wagons, and corsets. To these should be added the foundries and iron-working shops with their products, and the railways for the prosperity of modern Mexico. Perhaps the most important of these industries are those for the manufacture of bricks, and mills, of which there are 13, and the cigar and cigarette factories, of which there are 10. In the suburbs, oils, chemicals, cigarettes and tobacco are manufactured. There are also factories at Angel and Talajam; paper and boots at Tacubaya, and bricks at Mixcoac and Coyocan. A little farther away are the wooden mills of San Lázaro, the paper-mills of San Rafael, and important works for the manufacture of railway rolling stock.

The railway connections include direct communication with one port on the Gulf coast and with two on the Pacific—lines were under construction in 1906 to two other Pacific ports—and indirect lines with other Atlantic ports in the Gulf. The Mexican and all oceanic lines connect with Vera Cruz, the Mexican Central with Manzanillo, via Guadalajara and Colima, and the Vera Cruz & Pacific (from Cordoba) with the Chihuahua line and the railway of Salina Cruz. The last-mentioned line also gives indirect connection with the port of Coatzacoalcos, and the Mexican Central, via San Luis Potosi, with Tampico. A southern extension of the Mexican Central, from Cuitláhuac, has reached the Chihuahua line and the Pacific. The line is being extended to Acapulco, once the chief Pacific port of Mexico and the depot for the rich Philippine trade. A Mexican extension of the (American) Southern line, which has already been completed, is to be extended to Guadalajara, which will give the country national capital direct communication with the thriving ports of Mazatlan and Guaymas. In addition to these, the Mexican Central and Mexican National, now consolidated, give communication with the northern capitals and the United States, and the Mexican Southern runs southward, via Puebla, to the city of Oaxaca. These railways, with the shorter lines radiating from the city, connect it with nearly all the state capitals and principal ports.

The population by the census of 1900 was 344,721—an increase of 14,947 over the returns of 1895. The great majority of the inhabitants is composed of Indians and half-breeds, with a large proportion of people engaged in domestic service in the city, comprise the factory workers, labourers, servants, porters and other menial wage-earners. In former times Mexico was overrun with mendicants (pordarderos), vagrants and criminals (rateros), and the country was often described as a “hunting-ground” for them because of its proximity to the cathedral; but modern conditions have largely reduced this evil. The foreign population includes many capitalists and industrialists with manufacturing interests, and the American colony being concentrated in a fine modern residential district on the west-south-west side of the city.

History.—The City of Mexico dates, traditionally, from the year 1325 or 1337, when the Aztecs settled on an island in Lake Texcoco. The Aztec name of the city was Tenochtitlán, derived either from Tenoch, one of their priests and leaders, or from teuxch, the Indian name for the "nopal," which is associated with its foundation. The modern name is derived from Mexi, one of the names of the Aztec god of war Huiztilopochtli, which name was later on applied also to the Aztecs themselves. The island settlement, which was practically a lake-village built on islets—some of them undoubtedly artificial, and perched on stakes—grew rapidly with the increasing power and civilization of its inhabitants, who had not only the support of an impregnable position (Toluca, Tenango and other towns) to assist in their development. About the middle of the 15th century their mud-and-rush dwellings were partly replaced by stone structures, grouped around the central enclosure of the great teocalli, and bordering the causeways leading to the mainland. The town had reached its highest development when the Spaniards appeared in 1519, when it is said to have had, including suburban towns, a total of 60,000 dwellings, representing about 300,000 inhabitants. It was at that time about 13 m. in circumference, everywhere intersected by canals, and connected with the mainland by six long and solidly constructed causeways, as shown in the plan given in the edition of Cortes's letters published at Nuremberg in 1524 (reproduced in vol. i. of H. H. Bancroft's History of Mexico, San Francisco, 1883, p. 280). Allowance should be made for the habit of exaggeration among the Spanish adventurers of that time, and also for the diplomacy of Cortes in magnifying his exploits to win the favour of his king. The truth is, without doubt, that the dwellings of the lower classes were still built of reeds and mud, and covered the greater part of the city's area, the two famous imperial pyramids (the Teyacac and the Teotihuacan) on the east side; the old public buildings and private houses of the Spanish soldiers, without tools and explosives, could so easily have levelled it to the ground. After its almost total destruction in November 1521, Cortes employed some 400,000 natives in rebuilding the city on its former site. Since then the lake has decreased greatly in extent, its area being reduced to 11 square m. and its shore-line being more than 3 m. distant from the city it once surrounded. During Spanish rule the only break in the ordinary course of events was the revolt of 1692, which resulted in the destruction of the municipal buildings. The city was not much disturbed by the struggle for independence,
but it was afterwards the scene of many a revolution until the dictatorial authority of Porfirio Diaz put an end to petty pronunciamientos and partisan intrigues.

In the war between Mexico and the United States the most decisive campaign was that of General Winfield Scott directed against the Mexican capital. With the advanced guard of an army of about 10,000 men he arrived on the 19th of August 1847 at Ayolte, on the national road 16 m. south-east of the city; but as the approaches from this direction were very strongly fortified he cut a new road southward along the eastern shore of Lake Chapal and westward along the southern shore of lakes Chapal and Xochimilco to San Augustin, where his army arrived on the 17th and 18th of August. The city was now 10 m. distant, and the Mexican resistance was considerable. San Antonio, only 3 m. ahead, was strongly fortified, another short detour was made to the westward by cutting a road through a field of broken lava. This movement brought the Americans to the hill of Conterras, which was held by General Valencia with a force of some 7000 and 22 pieces of artillery, while President Santa Anna was in the neighbourhood with reinforcements numbering 12,000 or more. The Mexicans were routed on the morning of the 20th of August after suffering heavy losses. San Antonio was easily taken about noon of the same day, and in the afternoon the adjutant of the Mexican army was driven from the stone church and intermentchments at Churubusco. Three days later General Scott agreed to an armistice, but Mexico rejected the terms of peace, and hostilities were resumed on the 7th of September. During the armistice the American troops were quartered in and about the village of Tacubaya, about 2½ m. west by south of the city. Near Tacubaya, on the north by west, were some massive stone buildings known as El Molino del Rey, or the King's Mill. When attacked by the Americans under the immediate command of General W. J. Worth in the early morning of the 8th of September the Mexicans were supported by 13,000 men under Generals Leon, Alvarez and Perez, and they were captured only after a most desperate fight, which cost the Americans 787 killed and wounded and the Mexicans at least 2000 killed, wounded, and prisoners. To enter the city by way of the Tacubaya causeway it was still necessary for the Americans to capture Chapultepec. This hill, defended by about 4000 Mexicans under General Nicolas Bravo, was bombarded on the 12th of September, and was carried by assault on the 13th. On the following day the City of Mexico surrendered. It was then that the American army under General Winfield Scott, and held by them until signing of the treaty of Guadalupe-Hidalgo (May 1848).

The French intervention of 1861 led to a second occupation by a foreign power—a French military force under General Forey, taking possession in June 1863. Maximilian, archduke of Austria, was crowned emperor of Mexico in the cathedral in June 1864, and held possession of the capital until the 21st of June 1867, when it was captured by General Porfirio Diaz. Earthquake shocks are of frequent occurrence, but the city rarely suffers any material damage. The great earthquake shocks of the 30th and 31st of July 1900, however, caused considerable damage in the city, and a few lives were lost.

**MEXICO FEDERAL DISTRICT**

It was formerly a large territory set apart for the independent and exclusive use of the Mexican Federal Government, occupying the south-eastern part of the Valley of Mexico, and taken from and lying within the State of Mexico, which forms its boundaries on all sides except the south where it touches the state of Morelos. *Pop. (1900), 540,478, largely Indian and half-breeds; area, 463 sq. m., or accordingly to later computation 1408 sq. kilom. (578 sq. m.). The district is very irregular in outline, its greatest length (N. W. to S. E.) being 30 m., and its greatest breadth 25 m.* It was formerly divided into one urban municipality and four rural prefectures, but under the law of the 26th of March 1903 it is divided into 13 municipalities, Mazatepec, Guadalajara-Hidalgo, Atzacapotla, Tacubaya, Mixcoac, Cuajimalpa, San Angel, Coyoacan, Tlapalán, Xochimilco, Milpa Alta and Ixtapalapa; the first of these comprises the national capital and its immediate suburbs, and the other 12 the unequal divisions of the district with a considerable number of towns and villages. Indians and half-breeds form more than one-half of the rural population engaged in agriculture and gardening, beside which there is a large percentage employed in manufacturing industries. The government of the district is exercised by the national executive in accordance with the organic law of 1903, which provides that the popular government is vested in municipal councils (ayuntamientos) elected by popular vote for terms of four years. These councils have lost much of their original legislative character, but they must be consulted in matters of local importance, such as water supply, sanitary works, and the exploitation or sale of municipal property, and in regard to all contracts affecting the municipality. They can veto by a two-thirds vote the execution of any contract or administrative project, which then, at the end of four months, if again vetoed must be taken before the President of the Republic. All land, city and federal, is vested in the national executive, composed of the president, the viceroy, the governors of the federal district, the director-general of public works, and the president of the superior board of health. The three form a superior council of district government which exercises a supervisory and advisory power, " revising, confirming, reforming or revoking the acts of each one of the members of the council, whenever these acts are called in question." The council also exercises a general supervision of the making of contracts. The governor represents the national government, and in this capacity issues the general and special orders, the orders, and the requisitions and festivities, civil registry, street traffic, inspection of weights and measures, and the sale of intoxicating liquors. The director-general of public works has special charge of the water supply, streets and roads, parks, monuments, public lighting, drainage, street cleaning, public buildings not under federal control, cemeteries, slaughter-houses and markets, building operations, and all municipal or communal property. The president of the superior board of health has charge of all public health matters, sanitary inspection, the sanitary administration of markets, slaughter-houses, and the introduction of meats from other localities. The government of the district is copied, in part, from that of the District of Columbia in the United States, but its citizens are not disfranchised. They elect the ayuntamientos, which exercise no slight influence in local affairs, and, like any state, elect senators and deputies to the National Congress.

The principal towns of the district, some of which are merely suburbs of the capital, are Guadalupe, Tacubaya, Tlapalán and Xochimilco. Within the municipal limits of Mexico City are Chapultepec, Santa Anita and the hot springs of El Peñón, which are popular suburban resorts easily reached by the ordinary urban tramway service. Chapultepec (Grasshopper Hill) is an isolated rock nearly 200 ft. high surrounded by a beautiful park and surrounded by a fortified sanctuary called the "Castle," containing the summer residence of the president and the national military school. A finely graded road leads to the summit. The park contains a grove of old cypress trees (Taxodium distichum), called "ahuauctes" by the natives), one of which is 44 ft. in circumference and nearly 200 ft. high. The hill is nearly 3 m. south-west of the city and once commanded one of its principal causeways from Mexico City, near the shore of Lake Texcoco. It was occupied by forces under General Winfield Scott on the 13th of September 1847, after a stubborn resistance. A monument to the cadets of the military school who died in this battle stands in the park. The castle, which was built by the victory, was greatly admired by the emperor Maximilian, who planned for it the drive known as the Paseo de la Reforma. Of the neighbouring towns Guadalupe or Guadalupe-Hidalgo (pop. 5814 in 1900), 23 m. north by east of Mexico City, much resembles Guadalupe, for its shrine to Our Lady of Guadalupe, who is said to have appeared there to the Indian Juan Diego in 1531. The shrine stands on the
MEXICO, GULF OF—MEYER, J. L.

principal plaza and is visited by many thousands of pilgrims during the year, whose pious contributions have so enriched the church that its sacred vessels, altar-rails, candleabra and other adornments are of the greatest value. In the town church, the seat of an episcopal see, is the tomb of the late Gen. Alvarado, and of another distinguished son of the town, Gen. J. A. Mora, who died in the United States. The church is considered one of the most interesting in the republic, and is devoted to the cult of the Virgin of Guadalupe.

MEXICO, GULF OF, a Mediterranean gulf almost surrounded by Mexico, the Yucatan, and the coasts of the United States and Mexico, and forming the northern division of the extension westward of the west Atlantic trench (see Atlantic Ocean). Its southern boundary is defined by the partly submerged ridge which extends eastward from the peninsula of Yucatan, and on which the island of Cuba is situated: to the east it communicates directly with the Atlantic by the strait of Florida. On the western side of Yucatan a southerly embayment is formed by the Gulf of Campeachy. The United States coast closely parallels the 30° N., while the parallel of 20° N. cuts across the Gulf of Campeachy. The greatest length—Vera Cruz to Florida—is 1,200 m., and greatest width—Galveston to Campeachy—680 m. The total area is approximately 716,000 sq. m. The deepest part of the Gulf of Campeachy, the so-called "Sigsbee" deep, lies below the line of 2,000 fathoms, between 23° and 25° N., and 84° to 95° W. It is widest to the west, where the breadth is about 120 m., and narrows to 25 m. at its greatest depth (2,119 fathoms) between 80° and 88° W., widening again to some 80 m. farther eastward. The continental shelf is for the most part a very narrow one. The breadth is about 5 m. west-south-west of the Gulf Stream, 10 m. south of the Mississippi, 130 m. near the boundary of Texas and Louisiana, and 15 m. off Vera Cruz. The shores are low, sandy and marshy, the coast-line being frequently doubled by lagoons.

There are no islands except the "Keys" of Florida and Yucatan, and Cuba. The tides in the Gulf of Mexico are of comparatively small range (springs rarely exceed 4 ft. and neaps 2 ft.), but a remarkable feature is the exaggeration of the diurnal inequality to such an extent as almost to extinguish the semi-diurnal tide in the Gulf, though caused by the moon's attraction on the water only once daily. The mean level of the water in the Gulf of Mexico, as given by the United States Geographical Survey, is 35 feet below the level of the Caspian Sea, or 7 feet below the level of the Mediterranean; and 15 feet below the level of the sea at New York, as given by the United States Signal Service. The coast is relatively low, as is shown by the fact that the Gulf Stream, which issues from the remains of the northward moving water, forms the Antilles current.

From March to September the prevailing winds are the north-east trades; these undergo considerable modification on account of the configuration of the surrounding land, and the rains which accompany them are interrupted by spells of calm thick weather, and rarely by northerly winds known as Norte del hielo, Colorado and Cholulote on. In the colder dry season, from October to April, the climatic situation is dominated by the relatively high temperature of the Baltic Sea. The gulf, causing a cyclonic inflow of air which is associated with the strong northerly winds, "nortes" prevailing on the western side, more particularly along the Mexican coast. The northerns sometimes blow with terrific force and are at times accompanied by rain. The form and position of the Gulf of Mexico exercise a profound influence on the climate of the whole of the southern and south-eastern states of the Union, and of the greater part of North America.

MEYER, CHRISTIAN ERICH HERMANN VON (1801–1869), German palaeontologist, was born at Frankfort-on-the-Main, on the 3rd of September 1801. In 1832 he issued a work entitled Palaeologica, and in course of time he has been a recipient of various memoirs on various fossil organic remains: mollusca, crustacea, fishes and higher vertebrata. His more elaborate researches were those on the Carboniferous amphibila, the Permian reptiles, the Triassic amphibila and reptiles, and the reptiles of the Lithographic slates; and the results were embodied in his great work Zur Fauna der Verwall (1845–1860), profusely illustrated with plates drawn on stone by the author. He was associated with W. Dunker and K. A. Zittel in the publication of the Palaeontographica, which begun in 1852. He was awarded the Wollaston medal of the Geological Society of London in 1858. He died on the 2nd of April 1869.

MEYER, HEINRICH AUGUST WILHELM (1800–1873), German Protestant divine, was born at Gota on the 10th of January 1800. He studied theology at Jena, and eventually became (1841) pastor, member of the consistory, and superintendent at Hanover. He died on the 21st of June 1873. He is chiefly noted for his valuable Kritische exegetische Kommentar zum Neuen Testament (16 vols.), which began to appear in 1852, was completed in 1859 with the assistance of J. E. Huther, Friedrich Duersterbeck and G. K. Lüdemann, and has been translated into English. New editions have been undertaken by such scholars as A. B. Ritschel, B. Weiss, H. Wendt, K. F. G. Heinrici, W. Beyschlag and F. A. E. Sieffert.

Meyer also published an edition of the New Testament, with a translation (1829) and a Latin version of the symbolic books of the Lutheran Church (1830).

He is not to be confounded with Johann Friedrich von Meyer (1772–1849), the senator of Frankfort, who published a translation of the Bible in 1816 (Die heilige Schrift in berichtiger Übersetzung mit kurzen Anmerkungen; 2nd ed., 1828, 3rd ed., 1845).

MEYER, JULIUS LOTHAR (1830–1905), German chemist, was born on the 9th of August 1830, at Varel in Oldenburg. He was the son of a physician, and went to study medicine first at Zurich University in 1851, and then, two years later, at Wurzburg, where he had R. Virchow as his teacher in pathology. The influence of C. F. W. Ludwig, under whom he studied at Zurich, decided him to devote his attention to physiological chemistry, and therefore he went, after his graduation (1854), to Heidelberg, where R. Bunsen held the chair of chemistry. There he was influenced by G. R. Kirchhoff's mathematical teaching that he took up the study of mathematical physics at Königberg. Newell followed, and in 1863 Meyer became professor of physical chemistry at Breslau, where in the preceding year he had graduated as Ph. D. with a thesis on the action of carbon monoxide on the blood. In 1866 he accepted a post in the School of Forestry at Neustadt-Eberswalde, but soon moved to Carlsruhe Polytechnic. During the Franco-German campaign the Polytechnic was used as a hospital, and he took an active part in the care of the wounded. Finally, in 1876, he became professor of chemistry at Tubingen, where he died on the 11th of April 1895. His name is best known for the share he had in the periodic classification of the elements. He noted, as did J. A. R. Newland, in England, that if they are arranged in the order of their atomic weights they fall into groups in which similar chemical and physical properties are repeated at periodic intervals; and in particular he showed that if the atomic weights are plotted
Meyer, K. F.—Meyerbeer

as ordinates and the atomic volumes as abscissae, the curve obtained presents a series of maxima and minima, the most electro-positive elements appearing at the peaks of the curve in the order of their atomic weights. His book on Die modernen Theorien der Chemie, which was first published in Breslau in 1864, contains a discussion of relations between the atomic weights and the properties of the elements. In 1882 he received from the Royal Society, at the same time as D. J. Mendeleéff, the Davy medal in recognition of his work on the Periodic Law. A younger brother, O. E. Meyer, became professor of physics at Breslau in 1884.

Meyer, Konrad Ferdinand (1825-1899), Swiss poet and novelist, was born at Zürich on the 11th of October 1825. After studying law at the university, he went for considerable periods to Lausanne and Paris, and in Italy he interested himself in historical research. In 1875 he settled at Kilchberg near Zürich, was created in 1880 a doctor philosoplicus honoris causa by that university, and died at Kilchberg on the 28th of November 1898. After Gottfried Keller, Konrad Meyer is the most important Swiss poet of modern times, though as a novelist he was perhaps more successful. His poetical works include Balladen (1857); Romanzen und Bilder (1870); the epic poem, Huldens letzte Tage (1871); and Gedichte (1852; 20th ed., 1901).

Among his novels must be specially mentioned Jürg Jungen (1864); Erinnerung an die Stadt Breslau (1869); Der Heilige (1880; 12th ed., 1894; English by M. von Wendumbe, Thomas à Becket, the Saint, 1885); Die Richterin (1885); Die Versuchung des Pescara (1887); Angela Borgia (1891).

His shorter stories were collected in two volumes in 1885 (5th ed., 1892).

Meyer, Marie Paul Hyacinthe (1849—), French philologist, was born in Paris on the 17th of January 1849. He was educated at the Ecole des Chartes, and in 1869 was attached to the manuscript department of the Bibliothèque Nationale. In 1876 he became professor of the languages and literatures of southern Europe at the Collège de France. In 1882 he was made director of the Ecole des Chartes, and a year later was nominated a member of the Academy of Inscriptions. He was one of the founders of the Revue critique, and a founder and the chief contributor to Romania (1872). Paul Meyer began with the study of Old French literature, but subsequently did valuable work in many different departments of romance literature, and ranks as the chief modern authority on the French language. He is the author of Rapports sur les documents manuscrits de l'ancienne littérature de la France conservés dans les bibliothèques de la Grande Bretagne (1871); Recueil d'anciens textes bas-latins, provençaux et français (2 parts, 1874-1876); Alexandre le Grand dans la littérature française du moyen âge (2 vols., 1886). He edited a great number of old French texts for the Société des auteurs textes français, the Société de l'histoire de France and independently. Among these may be mentioned Aye d'Avignon (1861), with Guissard; Flamenca (1865); the Histoire de Guillaume le Maréchal (3 vols., 1892-1903); Raoul de Cambrai (1882), with A. Longin; Fragments d'une vie du Saint Thomas de Cantorbéry (1883); Guillaume de la Barre (1894).

Meyer, Victor (1848-1897), German chemist, was born at Berlin on the 8th of September 1848, and studied at Heidelberg University under R. W. Bunsen, H. F. M. Kopp, G. R. Kirchhoff and H. C. J. P. von Halbomtz. At the age of twenty he entered J. F. W. A. Baeyer's laboratory at Berlin, attacking among other problems that of the composition of camphor. In 1871, on Baeyer's recommendation, he was engaged by H. von Fehling as his assistant at Stuttgart Polytechnic, but within a year he left to succeed J. W. Wielanzen at Zürich. There he remained for thirteen years, and it was during this period that he devised his well-known method for determining vapour densities, and carried out his experiments on the dissociation of the halogenes. In 1882, on the death of W. Weith (1844-1881), professor of chemistry at Zürich University, he undertook to continue the lectures on benzene derivatives, and this led him to the discovery of thiophen. In 1885 he was chosen to succeed Hans Hünke (1837-1884) in the professorship of chemistry at Göttingen, where stereo-chemical questions especially engaged his attention; and in 1889, on the resignation of his old master, Bunsen, he was appointed to the chair of chemistry in Heidelberg. He died on the 8th of August 1897. In recognition of his brilliant experimental powers, and his numerous contributions to chemical science, he was awarded the Davy medal by the Royal Society in 1893.

Meyerbeer, Giacomo (1791-1863), German composer, first known as Jakob Meyer Beer, was born at Berlin on the 5th of September 1791,¹ of a wealthy and talented Jewish family. His father, Herr Beer, was a banker; his mother, Amalie (née Wulff), was a woman of high intellectual culture; and two of his brothers distinguished themselves in astronomy and literature. He studied the pianoforte, first under Lauska, and afterwards under Lauska's master, Clementi. When seven years old he played Mozart's Concerto in D Minor in public, and at nine he was pronounced the best pianist in Berlin. For composition he was taught by M. von Zelter, and under the influence of Bellini he produced a series of operas, and became the first director of the Berlin opera, by whom he was introduced to the Abbé Vogler. Vogler invited him to Darmstadt, and in 1810 received him into his house, where he formed an intimate friendship with Karl Maria von Weber, who also took daily lessons in counterpoint, fugue and extempore organ-playing. At the end of two years the grand duke appointed Meyerbeer composer to the court.

His first opera, Jephthah's Géline, failed lamentably at Darmstadt in 1811, and his second, Wirch und Gad (Albinkid), at Vienna in 1814. These failures discouraged him so much that he feared he had lost his vocation. Nevertheless, by advice of Salieri he determined to study vocalization in Italy, and then to form a new style. But at Venice he was so captivated by Rossini that, renouncing all thought of originality, he produced a succession of seven Italian operas—Romilda e Costanza, Semiramide riconosciuta, Eduardo e Cristina, Emma di Resurgo, Margherita d'Anjou, L'Esule di Granata and Il Crociato in Egitto—which all achieved a success as brilliant as it was unexpected. Against this act of treason to German art Weber protested most earnestly; and before long Meyerbeer himself grew tired of his detection. An invitation to Paris in 1826 led him to review his position dispassionately, and he came to the conclusion that he was wasting his powers. For several years he produced nothing in public; but, in concert with Scribe, he planned his first French opera, Robert le Diable. This gorgeous spectacle was produced at the Grand Opéra in 1831. It was the first of its race, a grand romantic opera, with situations more theatrically effective than any that had been attempted either by Cherubini or Rossini, and with ballet music such as had never yet been heard, even in Paris. Its popularity exceeded all expectations; yet for five years Meyerbeer appeared before the public no more.

His next opera, Les Huguenots, was first performed in 1836. In gorgeous colouring, rhetorical force, consistency of dramatic treatment, and careful accentuation of individual types, it is at least the equal of Robert le Diable. In two points only did its interest fall short of that inspired by the earlier work. Meyerbeer had shown himself so eminently successful in his treatment of the supernatural that one regretted the omission of that element; and, more important still, the fifth act proved to be an anti-climax. The true interest of the drama culminates at the close of the fourth act, when Raoul, leaping from the window to his death, leaves Valentine fainting upon the ground. The opera now usually ends at the fourth act.

After the production of Les Huguenots Meyerbeer spent many years in the preparation of his next greatest works—L'Africaine and Le Prophète. The libretti of both these operas were furnished

¹ Or, according to some accounts, 1794.
by Scribe; and both were subjected to countless changes; in fact, the story of *La Africaine* was more than once entirely rewritten.

Meanwhile Meyerbeer accepted the appointment of kapellmeister to the king of Prussia, and spent some years at Berlin, where he produced *Ein Feldherr in Schlesien*, a German opera, in 1834, and *L'Africaine*, his first appearance in Prussia. Here also he composed, in 1836, the overture to his brother Michael's drama, *Satanas*. But his chief care at this period was bestowed upon the worthy presentation of the works of others. He began by producing his dead friend Weber's *Euryanthe*, with scrupulous attention to the composer's original idea. With equal unselfishness he procured the acceptance of *Rienzi* and *Der fliegende Holländer*, the first two operas of Richard Wagner, who, then languishing in poverty and exile, would, but for him, have found it impossible to obtain a hearing in Berlin. With Jenny Lind as prima donna and Meyerbeer as conductor, the opera flourished brilliantly in the Prussian capital; but the anxieties materially shortened the composer's life.

Meyerbeer produced *Le Prophète* at Paris in 1839. In 1843 he brought out *L'Etoile du nord* at the Opéra Comique, and in 1839 *Le Pardon de Ploërmel* (Dinorah). His last great work, *L'Africaine*, was in active preparation at the Académie when, on the 23rd of April 1863, he was seized with a sudden illness, and died on the 2nd of May. *L'Africaine* was produced with piou and attention to the composer's minutest wishes, on the 28th of April 1863.

Meyerbeer's genius was criticized by contemporaries with widely different results. Mendelssohn thought his style exaggerated; Félix thought him one of the most original geniuses of the age; Wagner ungratefully calls him "a miserable音乐家," and "a Jewish banker to whom it occurred to compose operas."

The reality of his talent has been recognized throughout all Europe; and his name will live so long as intensity of passion and power of dramatic treatment are regarded as indispensable characteristics of dramatic music. His works show that these qualities, with the aid of an experienced stage-writer, be entirely independent of genuine musical insight.

**Meynell, Alice Christiana** (1850–1916), English poet and essayist, was the daughter of T. J. Thompson. Her early life was spent chiefly in Italy, and she was educated by her father. Her first volume of verse, *Preludes* (1873), illustrated by her sister Elizabeth, afterwards Lady Butler, attracted little public notice, but the delicacy and beauty of the poems and especially of the sonnet "Renunciation," were warmly praised by Ruskin. She married in 1877 the well-known Roman Catholic journalist and author Wilfrid Meynell, who became proprietor and editor of the *Weekly Register*. Under W. E. Henley's editorship, the magazine wrote regularly in prose for the *National Observer*, and also later for the *Pall Mall Gazette*, the *Saturday Review*, &c. Her poems (1893), including much of the earlier volume of *Preludes*, brought her at last more definitely before the public; and this was followed in 1901 by another slender book of delicate verse, *Later Poems*. Mrs Meynell also showed herself a fine critic of poetry by her admirable selection, *The Flower of the Mind* (1897), an anthology of English verse. She edited the *Selected Poems* (1894) of T. G. Hake, the *Poetry of Pathos and Light* (1895) of her intimate friend Coventry Patmore, and the selections from Patmore in the "Muses' Library." Her prose essays, remarkable for finish of culture and peculiar restraint of style, appeared in successive volumes as *The Rhythm of Life* (1893), *The Colour of Life and other Essays* (1896), *The Children* (1897), and *The Spirit of Place* (1898). Later books are *London Impressions* (1898) and *The Work of John S. Sargent* (1903).

**Meyer, Melchior** (1810–1871), German poet, novelist and philosopher, was born at Ehringen on the 28th of June 1810, and died at Munich on the 22nd of April 1871. He read law and philosophy at Heidelberg and Munich. His greatest success was the *Erzählungen aus dem Kriege* (4th ed. Leipzig, 1892), remarkable as an accurate and sympathetic picture of rural life and character. He wrote also tragedies (Hersz Og Abrahm, 1837; *Karl der Kühne*, 1852), novels (*Vier Deutsche, 1861; Zwinge Liebe, 1864*), and, in later life, philosophical works with a strong religious tendency. Among these were *Einleitung* (philosophical dialogues, 1863), *Die Religion des Geistes* (1871), *Die Fortdauer nach dem Tode* (1892), *Die Religion war ihre jetzt geborene Fortbildung* (1872), and *Gedanken über Kunst, Religion und Philosophie* (1874). In these works he attempted to develop a Deistic system of philosophy. He was the author of an anonymous work entitled *Gespräche mit einem Grobian* (1860).

**Meyrifab**, a small semi-Nomad tribe of Africans of Semitic stock, settled on the east bank of the Nile near Berber. Contrary to Arab custom, it is said they never marry slaves.

**Mézeray, François Edouard de** (1616–1683), French historian, was born at Rye near Argentin, where his father was a surgeon. He had two brothers, one of whom, Jean Edouard, was the founder of the order of the Eudists. François studied at the university of Caen, and completed his education at the college of Ste Barbe at Paris. His *Histoire de France depuis Paramond jusqu'à Louis le Juste* (3 vols., 1643–1651), is a fairly accurate summary of French and Latin chronicles. Mézeray was appointed historigrapher of France, and in 1649, on the death of Vincent Voiture, was admitted to the Académie Française. His *Abrégé chronologique* (3 vols., 1667–1668) went through fifteen editions between 1668 and 1717; *Die Religion war ihre jetzt geborene Fortbildung* in this work to attack the financiers, with the result that his salary as historigrapher was diminished by Colbert. Mézeray succeeded Conrart as permanent secretary to the Académie Française (1659), and died at Paris on the 10th of July 1683. He translated Grotius's *Traité de la religion chrétienne* (1649), and a *Histoire des Turcs depuis 1012 jusqu'en 1649* (1650), which is an addition to a continuation of Chalcedydes.

See *Daniel de Larroque, Vie de François Edouard de Mézeray* (1795); *Weiss, Geschichte des Buchdruckes in Frankreich* (1855); *Larroque's Notice sur les trois frères: Jean Edouard, François Edouard, et Charles Edouard* (1855).

**Mézières, Philippe de** (c. 1372–1459), French soldier and author, was born at the château de Mézières in Picardy. He belonged to the poorer nobility, and first served under Lucchino Visconti in Lombardy, but within a year he entered the service of Andrew, king of Naples, who was assassinated in September 1342. Having in the autumn of 1343 been sent out for the East in the French army. After the battle of Smyrna, he became a knight, and when the French army was disbanded he made his way to Jerusalem. He realized the advantage which the discipline of the Saracens gave them over the disorderly armies of the West, and conceived the idea of a new order of knighthood, but his efforts proved fruitless. The first sketch of the order was drawn up by him in his *Novo religio passionis* (1356–1358; revised and enlarged in 1356 and 1390). From Jerusalem he found his way in 1347 to Cyprus to the court of Hugo IV., where he found a devoted enthusiast in the king's son, Peter of Lusignan, then count of Tripoli; but he soon left Cyprus, and had resumed his career as a soldier of fortune when the accession of Peter to the throne of Cyprus (Nov. 1358) and his recognition as king of Jerusalem induced Mézières to return to the island, probably in 1360, when he became chancellor. He came under the influence of the pious legate Peter Thomas (d. 1366), whose friend and biographer he was to be, and Thomas, who became patriarch of Constantinople in 1364, was one of the chief promoters of the crusade of 1365. In 1362 Peter of Cyprus, with the legate and Mézières, visited the princes of western Europe in quest of support for a new crusade, and when the king returned to the east he left Mézières and Thomas to represent his case at Avignon and in the cities of northern Italy. They preached the crusade throughout Germany, and later Mézières accompanied Peter to Alexandria. After the capture of the city he received the government of a third part of it and a promise for the creation of his order, but the Crusaders, satisfied by the immense booty, refused to continue the campaign. In June 1366 Mézières was
sent to Venice, to Avignon and to the princes of western Europe, to obtain help against the Saracens, who now threatened the kingdom of Cyprus. His efforts were in vain; even Pope Urban V. advised peace with the sultan. Mézières remained for some time at Avignon, seeking recruits for his order, and writing his Vitae et memoriae, part of which he published in 1609, which is invaluable for the history of the Alexandrian expedition. The Preface and Epistola, which form the first draft of his work on the projected order of the Passion, were written at this time.

Mézières returned to Cyprus in 1368, but was still at Venice when Peter was assassinated at Nicosa in the beginning of 1369, and he remained there until 1372, when he went to the court of the new pope Gregory XI. at Avignon. He occupied himself with trying to establish in the west the basis of the presentation of the Virgin, the office of which he translated from Greek into Latin. In 1373 he was in Paris, and he was then employed one of the trusted counsellors of Charles V., although this king had refused to be dragged into a crusade. He was tutor to his son, the future Charles VI., but after the death of Charles V. he was compelled, with the other counsellors of the late king, to go into retirement. He lived there in the convent of the Celestines in Paris, but nevertheless continued to exert an influence on public affairs, and to his close alliance with Louis of Orleans may be put down the calumnies with which the Burgundian historians covered his name. When Charles VI. freed himself from the domination of his uncle the power of the Duke of Burgundy increased. To this period of his life belong most of his writings.

Two devotional treatises, the Contemplatio horae mortis and the Soliloquium peccatoris, belong to 1386-1387. In 1389 he wrote his Songe du vifé périr, an elaborate allegorical voyage in which he described the customs of Europe and the near East, and advocated peace with England and the pursuit of the Crusade. His Oriato iragédica, largely autobiographical, was written with similar aims. In 1395 he addressed to Richard II. of England an Épître pressing his marriage with Isabella of France. The Crown was involved in the war, and Mézières, in order to prevent the danger of Nicopis on the 28th of September 1396 justified his fears and was the occasion of his last work, the Épître lamentable et consolatoire, in which he put forward once more the principles of his order as a remedy against future disasters. Mézières died in Paris on the 29th of May 1405.

Some of his letters were printed in the Revue historique (vol. xli.), the two épitres just mentioned in Kervyn de Lettenhove's edition of Froissart's Chroniques (vol. xvi. and xvi.y.), the Songe du vifé périr on Songer were printed about 1576, is sometimes attributed to him, but without definite proofs.

See Antoine Becquet, Gallicae coelestinorum congregationis monasteria, fundationes ... (1710); the Abbé Jean Leboeuf's Mémoires sur les ordres de saint Pierre, etc. (3 vols. 1752 and 1753). J. Delavalle le Roux, La France en Orient au xiv. siècle (1886-1890); A. Molinier, Manuel de bibliographie historique vol. iv. (1901); and especially the researches of N. Jorga, published in the Bibliothèque de l'École des hautes études vol. 110 (Paris 1896); and the same writer's Philippe de Mézières, et le croisade au xiv. siècle (1896). Jorga gives a list of his works and of the MSS. in which they are preserved, and analyses many of them. In the Songe du vifé périr, see P. Paris, in Mémores vol. xv. (1843) of the Academy of Inscriptions.

MEZIERES, a town of northern France, capital of the department of Ardennes, 55 m. N.E. of Reims by the Eastern railway. Pop. (1906), town, 7000; commune, 9393. The town itself, the streets of which are narrow and irregular, is situated on the neck of a peninsula formed by a loop of the Meuse. The river separates it from its suburb of Arches and the town of Charleville on the north and from the suburb of Pierre on the south. Adjoining Pierre is Mohon (pop. 5874), with metallurgical works. The fortifications of Mézières, as well as the citadel still dominating the town on the east, were built under Vauban's direction, but were enlarged in 1896 and 1888. Immediately to the east of the citadel runs a canal, which provides river-traffic with a short cut across the isthmus. The parish church (16th cent.) contains inscriptions commemorating the raising of the siege of Mézières in 1521 and the marriage of Charles IX. with the daughter of the emperor Maximilian II. (1570). The north and south portals, the Renaissance tower at the west end, and the lofty vaultings, are worthy of remark. The church, which suffered severely in 1570-71, has since been restored. The prefecture and the hôtel de ville, which contains several interesting pictures relating to the history of the town, belong to the 18th century. Mézières is the seat of a prelate and of a court of assizes, and there are manufactories of bicycles, and iron and steel castings for motors, railway-carriages, &c.

Founded in the 7th century, Mézières was at first only a strong-hold belonging to the bishops of Reims, which afterwards became the property of the counts of Rethel. The town was increased by successive immigrations of the people of Liége, flying first from the emperor Otto, and afterwards from Charles the Bold; and also by concessions from the counts of Rethel. Walls were built in the 13th century, and in 1541 it was defended against the Imperialists by the Chevalier Bayard, to whom a statue was erected in 1803. The anniversary of the deliverance is still observed yearly on the 27th of September. In 1815 the Germans were kept at bay for six weeks, and in 1871 the town only capitulated after a bombardment during which the greater part of it was destroyed.

MEZÔTûR, a town of Hungary, in the county of Jász- Nagykun-Szolnok, 88 m. S.E. of Budapest by rail. Pop. (1900), 25,587. It possesses important potteries. Large herds of cattle are kept on the communal lands, which are productive also of wheat, rape seed and maize. Several well-attended fairs are held here annually.

MEZZANINE (It. mezzano; Fr. eniressel; Ger. Zwischengeschoss), in architecture, a storey of small height introduced between two lofty storeys, or sometimes employed to allow of the introduction of two storeys equal together in height to lofty rooms on the same floor.

MEZZOFANTI, GIUSEPPE CASPAR (1774-1849), Italian cardinal and linguist, was born on the 17th of September 1774, at S. Croce, in the diocese of Arezzo. He was ordained priest in 1797, and in the same year became professor of Arabic at the university, but shortly afterwards was deprived for refusing to take the oath of allegiance to the Cisalpine Republic. In 1835 he was appointed assistant librarian of the institute of Bologna, and soon afterwards was reinstated as professor of oriental languages and of Greek. The chair was suppressed by the viceroy in 1808, but again rehabilitated on the restoration of Pius VII. in 1814, and continued to be held by Mezzofanti until his removal from Bologna to Rome in 1831, as a member of the congregation de propaganda fide. In 1835 he succeeded Angelo Mai as kept of the library, and in 1852 was made cardinal and director of studies in the Congregation. He died at Rome on the 15th of March 1849. His peculiar talent, comparable in many respects to that of the so-called "calculating boys," was not combined with any exceptional measure of intellectual power, and produced nothing of permanent value. It seems certain, however, that he spoke with considerable fluency, and in some cases even with attention to dialectical peculiarities, some sixty or sixty languages of the most widely separated families, besides having a less perfect acquaintance with many others.

MEZZOTINT. During the 19th century two revolutions occurred in the British art of mezzotinto engraving—"la manière anglaise." The original defect of the method was the incapacity of the mezzotint "burr" on copper to yield as many fine impressions as other forms of engraving. To this defect was attributable the introduction, in 1825, of steel instead of the soft copper previously used—a change which, with the endeavour to avoid technical difficulties, led to the "mixed style," or combination of mezzotint with etching, and a general departure from the traditional form of the art, "pure mezzotint" on copper. The affinity of the method to painting in black and white which differentiates it from other kinds of engraving, and was the distinguishing charm of the mezzotints of the 17th and 18th centuries, was for a time lost, but a revival of pure mezzotint on
copper, beginning in 1880—a return, in fact, to the mode in which the classics of the art were engraved in the time of Sir Joshua Reynolds—was made possible by the invention of steel-facering. By this process engraved copper plates are electroplated with a film of steel, renewable when worn in course of printing; and a mezzotint on copper, so protected, yields more fine impressions than if it had been engraved on steel, whilst the painter-like quality remains unimpaired.

In “pure mezzotint” the design is evolved from dark to light entirely by scraping away more or less of the round “burr” or “grind,” which is left untouched in the extreme darks, and no acid, etching or line-work is used in it at all. The usual short descriptions of the method are misleading, because, when they fail to distinguish clearly the “burr” and the indentations out of which the “burr” is raised, they fail to appreciate the whole method. The “rocking-tool,” with which the “ground” is laid, is somewhat resembles a carpenter’s chisel, but the blade is 3 in. wide and only about 2 in. long, whilst the cutting edge, instead of being straight, is curved in the segment of a circle. One side of the blade is deeply engraved with lines from edge to handle, and the ridges which remain between these lines form teeth at the cutting edge which, when the unsharpened edge of the tool is bevelled as an ordinary chisel is sharpened.

The tools contain from 35 to 120 teeth to each inch of their width, those with the most teeth producing grounds of finer texture. The other side of the tool has the bevelled edge of the tool from side to side on the bare copper plate, causing the tool to travel forward, whilst each tooth makes an indentation in the copper and throws up a corresponding ridge on the surface, called a “full ground.” When the whole plate has been so rocked across in 45 to 60 different directions, so that no visible speck of the original bright copper surface remains unfelt by the teeth of the “rocking-tool,” the “ground” is termed “full,” and is ready for scraping the design. The innumerable particles of copper forming the raised “burr” give to a “full ground” much the appearance of copper-coloured plush; and a print from it, taken before any scraping has been done on it, looks not unlike a piece of black velvet. The lights and semi-tones of the design are produced by subsequent scraping and burnishing.

Assuming that a mezzotint is to be scraped from a lady’s portrait by Sir Joshua Reynolds in which a piece of black drapery crosses a white dress—the engraver begins to work on a previously laid “ground.” This ground would print uniformly black before scraping commencement. In the extreme darks of the black drapery the raised “burr” is left untouched by the “scraper”—a two-edged steel instrument resembling an ancient Roman sword-blade in miniature, but worked to a point. Working with a too dark a ground, the engraver produces the varying tones of the folds of the black drapery by scraping the raised “burr” down more or less, lowering it in fact so that it will not hold so much ink as where it is left untouched by the “scraper.” In the extreme darks of the black drapery, all the raised “burr” will have been removed and the original surface of the plate reached, but as yet the engraver has left untouched any lighter “burr,” which provides the difference between the blacks and the half-tints of the iris. When the indentations out of which the “burr” was raised still remain in the plate and hold ink in printing. In order to produce the infinite gradation of delicate tints in the white dress, or in a sky, the scraping is continued, the indentations being thus made shallower in the passages scraped, and therefore less capable of holding ink, whilst they are obliterated almost entirely in the highest lights. When the mezzotint is finished the black drapery will stand higher than the surface of the plate modelled in a relief composed of the raised “burr,” whilst all the tones of the white dress, from middle to light, will be so many degrees of the highest lights being the deepest. The speck of light in the eye, for instance, is a pit in the plate, surrounded by a tract of more or less light which provides the difference between the blacks and the half-tints of the iris. The difference of surface levels is very appreciable where high-lights impinge on strong darks, but it exists in varying degree all over the plate, and the greatest technical difficulty is, therefore, to obtain adequate definition, because the tendency is to remove too much “ground” from the edges of adjacent darks in the course of the constant scraping, while etching and linear lines remain.

In printing a mezzotint a non-fluid ink is thoroughly worked into every part of the plate, and the superficies wiped off again, leaving as much ink as possible in the darks, the raised “burr.” If the “burr” is too small lights are produced, and especially in the roughness and they print dark instead of light, or the printer has to wipe so hard to get the ink out of the depressed lights that he produces roughness in the darks. In either case loss of definition and contrast of effect results. This inherent difficulty of scraping to a sharp edge caused the use of the “mixed” methods, in which the details were sharpened by outlining them with stipple or line etching.

The mezzotint is the best form of engraving for completeness of representation, but etching is better adapted for sketching from nature or for the expression of any fleeting idea. The two arts have often been compared, and in fact the practice of the two was practiced by Rembrandt lies in economy of expressive line to suggest the artist’s meaning, and that of mezzotint in completion of tonality to explain it. Artistic suggestion, which is not inherent in the method of producing rough tones of black, is entirely by the free play of the “scraper” on the “ground,” much as the painter attains it on canvas with the brush.

Rupert brought the new art over to England at the Restoration, and the portrait of Charles II, dated 1669, by William Sherwin, was the first mezzotint executed in England. It was one of a series of his indebtedness to Rupert for the secrets of the method. Mezzotint continued to be practised for a while on the Continent, but the success of Sir William Sherwin was so remarkable, so well in it that it early spread abroad the title of “la manière Anglaise,” and has since become an exclusively British art. Though used for transcribing the subject-pictures of the great Italian masters, and of Rembrandt, Vandyck and Rubens, etching was the most usual method of engraving it, the staple production in mezzotint has almost always been the portrait. Until the middle of the 17th century the tools continued somewhat archaic, causing in the prints an appearance of great wood, like much of Dutch painting, derived from reality of representation. The coarseness and unequal depth of the “grounds” offered so much resistance to freedom of execution with the “scraper” that, though the early engravers were quite as great artists as their successors, painter-like touch was not conspicuous in the work until M’Ardell and the interpreters of Sir Joshua Reynolds had improved the tools and technique.

The mezzotint engraving of the best plates after Sir Joshua Reynolds by James M’Ardell, J. R. Smith and Valentine Green, the Watsons, Dickinson, Fisher, Dixon and some others, who worked during the last half of the 18th century. The brushwork of Reynolds was more in harmony with the mezzotint method than the slighter painting technique of Gainsborough and Romney, who were much less frequently engraved, perhaps because it is the highest technical difficulty in mezzotint to render the sharp edges of a sketch. For this reason Reynolds is more often represented by prints published by the mezzotint method. Though professional publishers and printers existed at this time and earlier, the word “executed” or an old print, implying “published,” not “engraved,” the authors of the “Sir Joshua mezzotints in most cases. To hold their own works, and pure mezzotint, unmixed with etching, was almost exclusively the method they employed. Mezzotints were occasionally printed in colours, notably those of engraved later by George Morland, the primary object being to convey the impression of the plates.

The departure from pure mezzotint and temporary decay of the art was due to the want of substitution, found in the work of Richard Earlom, otherwise a fine artist in the traditional method, notably in translations of Vandyck and Wright of Derby, began to outline the details of his plates with stipple etching in order to avoid the labour and difficulty of scraping an extensive ground. Earlom, however, did not destroy the mystery of the rich velvety darks by etching them into. A demand then arose for larger editions than the soft copper plates would yield, and the engravers attempted to meet it by combining mezzotint with

**History.**
positive line-etching throughout the work, thus shortening the labour of scraping the details, and fortifying the darks with lines sufficient to the purpose. The copper-plate line and tone in some of the prints in this style by S. W. Reynolds and Charles Turner, after Sir Joshua, Hopper and their contemporaries, was more evident to the eye than the latter "mixed style" of Samuel Cousins. In his Liber Studiorum series of landscape plates, his object being to rival the pen-and-wash drawings of Claude's Liber Veritatis. The copper-plate line being so powerful a tool as to make or mar the engravings before mentioned, and the etched foundation of the Liber plates was too strong for the mezzotint tone, destroying the breadth of the light and shadow values, and putting an end to that "key" or "backbone" effect of the whole effect. It is the grand design of Turner reflected in the plates, rather than any quality of mezzotint or etching in them, which appeals to the artist and the connoisseur.

The greatest success in harmonizing line and tone in one plate was achieved by David Lucas in his "English Landscape" series of mezzotint after John Constable, in which he sharpened his details with the roulette, or with a slight line put in with the point of the copper-plate scratcher, both scraping and scratching, in his darks. Lucas, like Samuel Cousins and his contemporaries, was handicapped by being compelled to work on the steel plates introduced in 1823, and this was the cause of the chief defects of his engravings, but with these difficulties he was able to raise a general tone which assisted the picturesque quality of the 18th century mezzotints was lost by the use of steel, because the ink did not cling to the blocks and the mezzotints were printed from copper, the rock-etching penetrated less deeply, raising less "burr." and the consequent loss of force in the darks necessitated the scraping up of the lights to a higher key to force contrast of effect, which was accomplished by the use of very white water paper and a coarse black ink. It was soon found that the unfortified "burr." even on steel, would not yield the constantly increasing numbers of impressions demanded. The labour of scraping sharp lights was greatly enhanced, and though some pure mezzotints were engraved on steel, painter-like touch was practically unattainable on it, and the general effect was cold and uninteresting.

Mezzotint was first thoroughly developed by Samuel Cousins and Lawrence in the comparatively pure method, and the final development of the "mixed style" on steel in his later plates after Reynolds, Millais and Landseer, are referred to in the article on Samuel Cousins. For many years pure mezzotint ceased to be practised altogether, and the revival of it, which began in 1880, was led up by the invention of steel-facing. The competition of photogravure, which steel-facing made a commercial possibility, for a time checked the new movement, but photogravure, despite its mere surface resemblance to a mezzotint, is a photograph manipulated to imitate an engraving, entirely devoid of artistic individuality. In 1897, at the first time a Society of Mezzotint Engravers was formed to foster the art.

AUTHORITIES.—British Mezzotint Portraits, by John Challoner Smith (London, 1878), a standard book of reference, contains a long list of mezzotints, with each engraved in full. The Notes on Mezzotint, Mezzotint Engravers, by Hubert von Herkomer, R.A. (London, 1890), the most useful work on the technique. Etching, Engraving and other Methods of Printing Pictures, by H. W. Singer and William Strang (London, 1897); On the Making of Etchings, by Frank Short (London, 1898), containing a slight reference to mezzotint technique; Art of Engraving, by T. H. Fielding (London, 1854); Alfred Whitman, Masters of Mezzotint (London, 1898); Valentine Green (1902); Samuel William Reynolds (1903); Samuel Cousins (1904); Turner (1907); Gordon Gordin, James Mc Ardell (1903); Thomas Watson, James Watson, Elizabeth Judkins (1904); W. G. Rawlinson, Techniques of Fine Art (1907); A Dictionary of Art (1906); F. Wedmore's catalogue of the David Lucas mezzotints. A little anonymous book, A History of the Art of Engraving in Mezzotint, from Its Origin to the Present Times (by Dr. James Chisholm, 1869), contains a chapter on the engravers, and the technique are somewhat elementary, and no complete history of the art exists.

MFUMBIO, or KIRUNGA, general names for a chain of volcanic mountains extending across the Central African, or Albertine, rift-valley immediately north of Lake Kivu. The range, the result probably of recent geological changes, completely closed off at this point, forming a divide between the rivers flowing north to the Nile and the waters of Lake Kivu connected through Tanganyika with the Congo system. The chain consists of two groups of mountains, surrounded by a vast lava field. The western group lies directly north of Lake Kivu, and contains two active volcanoes, Kirunga-changongo, the nearest to the lake (11,914 ft. high), and Kirunga-namaligira (1071 ft.), some 10 m. further north. The eastern group contains several higher peaks—some rising to needle-like points, others being truncated cones. The most lofty, Karisimbi (14,683 ft.), lies in 2° 27' 20" E., 1° 30' 20" S. Mikeno, a few miles north of Lake Albert, is Karisimbi, is 14,385 ft. high. The mass of the great central group is 1898 ft. high, and 1898 ft. high, is an isolated salt-woof-shaped mass with a crater filled with water on its summit. This is the mountain to which the names Mfumbiro and Kirunga were originally applied. Some 6 m. west and a little north of Muahavura is Salyino (Sabinjo), 11,881 ft. high. The eastern peaks are snowcapped for a part of the year. North of these high mountains is a district, extending towards Albert Edward Nyanza, containing hundreds of low peaks and extinct volcanoes. It is to this region that the name Umfumbiro of the Karmans is said properly to belong.

Mfumbiro, i.e. Muahavura, was first seen by a white man in 1851, J. H. Speke, in his journey to discover the source of the Nile, obtaining a distant view of the cone, which was also seen by H. M. Stanley in 1856. By its Baganda name of Mfumbiro (cook-house mountains) it figured on the maps somewhat east of its true position, first ascertained by Franz Stuhlmann in 1891. In 1894 Count von Götzen travelled through the volcanic region, and the range was subsequently explored by E. S. Grogan, Major S. Hill Gibbons, Captain Herrmann, Dr. R. Kandt and others. The principal objects of the volcanic region in 1907–1908 were geologically and topographically examined by the duke of Mecklenburg's expedition. By the Anglo-German agreement of the 1st of July 1890 "Mount Mfumbiro" was included in the British sphere in East Africa.

See Captain Herrmann, "Vulkangebiet des zentralafrikanischen Grabens," in Mittell. v. Forsch. u. Gegenb. d. deutschen Gesch. und der Kolonialbeh., xvii. (Berlin, 1904), and Adolf Friedrich, duke of Mecklenburg, Ins Innerste Afrika (Leipzig, 1909); both give maps.

MIHOW, a town of Central India, with British military cantonment, within the native state of Indore, on the Malwa branch of the Rajputana railway, 13 m. s. of Indore. Pop. (1901), 36,039. It is the headquarters of the 5th division of the southern army, and one of the chief military stations of India. There are two high schools, a Zoroastrian and a Canadian mission, the Dorabji Pestonji dispensary, and a gaol.

MIAGAO, a town on the southern coast of the province of Iloilo, island of Panay, Philippine Islands, about 25 m. W.S.W. of the town of Iloilo, the capital. Pop. (1903), 20,656; in the same year the neighbouring town of San Joaquin (pop. 1903, 14,335) was incorporated with Miagao. It has a cool and healthful climate, is well watered, and produces sibuca in considerable quantities. The weaving of fabrics of abacá (Musa textilis), or Manila hemp, and pineapple fibre is the most important local industry. The language is Panay-Visayan.

MIALL, EDWARD (1809-1881), English Nonconformist divine and journaler, was born at Portsmouth on the 8th of May 1809. He was Congregational minister at Ware (1831) and Leicester (1834), and in 1841 founded the Nonconformist, a weekly newspaper in which he advocated the cause of disestablishment of the Established Church. In 1854 he was appointed one of the editors of the programme of Nonconformism to be carried through it must have more effective representation in Parliament. One of the firstfruits of his work was the entrance of John Bright into parliamentary life; and by 1854 forty Dissenters were members of the House of Commons. This was due largely to the efforts of the Anti-State Church Association, afterwards known as the Liberation Society, which Miall had founded in 1844. The long fight for the abolition of compulsory church-rates was finally successful in 1868, and then in 1870 Miall was prominent in the discussions aroused by the Education Bill. He was at this time M.P. for Bradford (1867-1870), and of the Nile lights being detected. In 1874 he retired from public life, and received from his admirers a present of ten thousand guineas. He died at Sevenoaks on the 20th of April 1881. See the Life, by A. Miall (1884).
MIAMI, a city and the county-seat of Dade county, Florida, U.S.A., in the S.E. part of the state, on the N. bank of the Miami river and on Biscayne Bay. Pop. (1900), 1681; (1905), 4733 (1910), 5471. It is served by the Florida East Coast railway and by lines of coastwise steamships, and is the point of departure of the P. & O. steamships for Nassau and Havana. Miami is the centre of a farming country in which citrus fruits, especially grape-fruit, pineapples and winter vegetables are raised for northern markets. There is excellent rod-fishing; Spanish and king mackerel and blue-fish are shipped from Miami in large quantities; and in Biscayne Bay there are important sponge fisheries. An alligator "farm" and the Subtropical Laboratory of the U.S. government are points of interest. In the city is Fort Dallas (now abandoned), where American troops were quartered during the Seminole War; and Miami is still the trading point of the Seminole Indians, being immediately south of the Everglades, their home. In 1900 a project was on foot to cut a channel from Miami to Lake Okeechobee and from the other side of that lake west to the Gulf at Fort Myers, thus providing an inland waterway and draining much swampland but fertile land. In 1866 there were only two dwellings and one storehouse within the present corporate limits, but in that year the place was chosen as the southern terminal of the Florida East Coast railway, which was afterwards extended towards Key West. Soon afterwards Henry M. Flagler (b. 1830), the owner of the railway, began the construction of the magnificent Royal Palm hotel, and Miami became a popular winter resort. Then came the development of commerce by the improvement of the harbour, by donations from Mr Flagler and grants by the United States government.

MIAMI, a tribe of North American Indians of Algonquian stock. The English called them Twighitces, a corruption of the native name, which meant the cry of the crane. They were first found in south-eastern Wisconsin, and in 1764 numbered about 1730. Their civilization was advanced and they lived in stockaded towns. They took part in Pontiac's conspiracy in 1764 and in the American War of Independence and American War of 1812 they fought on the English side. At the close of this war they were greatly reduced in numbers. A few Miami still live on a reservation in Oklahoma and in Wabash county, Indiana.

MIANTONOMO (? -1643), chief of the Narraganset tribe of North American Indians, nephew of their grand sachem, Canonicus (d. 1647). He seems to have been friendly to the English colonists of Massachusetts and Connecticut, though he was accused of being treacherous. In 1636, when under suspicion, he went to Boston to prove his loyalty to the colonists. In the following year he permitted John Mason to lead his Connecticut expedition against the Pequot Indians through the Narraganset country, and in 1638 he signed for the Narraganset the tripartite treaty between that tribe, the Connecticut colonists and the Mohagan Indians, which provided for a perpetual peace between the parties, and he agreed to take under his jurisdiction eighty of the two hundred troublesome Pequot. In 1643 a quarrel broke out between the Mohogan and the Narraganset, and Miantonomo led his warriors against those of Uncas, the Mohogan sachem. He was defeated and captured at what is now Norwich, Conn., was turned over to the Connecticut authorities, and was later tried at Boston by the commissioners of the United Colonies of New England. A committee of five clergymen, to whom his case was referred, recommended that he be executed, and the commissioners accordingly sentenced him to death and chose Uncas as his executioner. Miantonomo, who was kept in ignorance of this sentence, was taken to the scene of his defeat and was there tomahawked in cold blood by Waywega, the brother of Uncas. There is a monument to Miantonomo in South's Park, Norwich, Conn.

MIAWALI, a town and district of India in the Multan division of the Punjab. The town is situated on the left bank of the Indus, 65 ft. above sea-level. Pop. (1901), 3591. The district was formed in 1901, after the creation of the North-West Frontier Province, out of the Cis-Indus portions of Bannu and Dera Ismail Khan districts. Area 7816 sq. m. Pop. (1901), 424,588, showing an increase of 6.4% in the decade. About three-quarters of the district lies to the east of the Indus. Along the river is a low fertile tract, liable to floods. The remaining upland, known as the Thal, is barren and sandy, cultivable only where irrigation is possible. In the north-east the district includes the western flank of the Salt Range. The part of the district to the east of the Indus is a varied and fairly fertile plain, bounded by the Chichali and Maidani hills. The chief agricultural products are wheat and other grains and oil-seeds. Hides and wool are also exported, together with small quantities of alum (abundant in the Salt Range), salt (from the Salt and Maidani ranges), and coal of poor quality, which is found at several points. Petroleum has been discovered. The district is served by the Multan-Rawalpindi line of the North-Western railway.

MIAOTZSE, or MIAUTSZE, one of the aboriginal tribes of southern China. At one time they occupied a considerable part of the fertile plain which now forms the central province of the empire, but as the Chinese advanced southwards they were driven into the mountain districts of the provinces of Yunnan, Kwei-chow, Kwang-si and Kwang-tung, where they are found at the present day. As early as the reign of King Suan (about 800 B.C.) we read of an expedition having been sent to drive them out of Hu-nan. The last important campaign against them was undertaken by the emperor K'i'en-lung, who, having completely subjugated the Eleuths, attacked the Miaotsze, who suffered a crushing defeat, and were compelled to purchase peace by swearing allegiance to their conquerors. The word Miaotsze, as used in their mountain-homes, but are a decaying race, gradually giving way before the Chinese. They are allowed to govern themselves on their own patriarchal system. The Miaotsze of both sexes are shorter and darker-complexioned than the Chinese, their faces are rounder and their features sharper.

MIAULIS, ANDREAS VOKOS or BOKOS (1768-1835), Greek admiral and politician, was born in Negropont. The surname Miaulis, which was added to his family name of Vokos, or Bokos, is said to be derived from the Turkish word miaoulis, a felucca. He settled in the island of Hydra on the east of the Morea, and when the Greek War of Independence began was known among his fellow townsmen as a trader in corn who had gained wealth, and who made a popular use of his money. He had been a merchant captain, and was chosen to lead the naval forces of the islands when they rose against the government of the Sultan. The islanders had enjoyed some measure of exemption from the taxes imposed on the rest of the empire, and the conscription raised to man the Turkish ships; and though they seemed to be peculiarly open to attack by the Sultan's forces from the sea, they took an early and active part in the rising. As early as 1822 Miaulis was appointed navarch, or admiral, of the swarm of small vessels which formed the insurgent fleet. He commanded the expedition sent to take revenge for the massacre of Chio (see KANARIS) in the same year. He continued to be the naval chief of the Greeks till Lord Dundonald entered their service in 1827, when he retired in order to leave the English officer free to act as commander. In the interval he had had full direction of the naval side of the Greek struggle for freedom. He had a share in the successful relief of the first siege of Missolonghi in December 1822 and January 1823. In 1824, after the conquest of Psara by the Turks, he commanded the Greek forces which prevented the further progress of the Sultan's fleet, though at the cost of the loss of many fire ships and men to themselves. But in the same year he was unable to prevent the Egyptian forces from occupying Navarino, though he harassed them with some success. During 1825 he succeeded in carrying stores and reinforcements into Missolonghi, when it was threatened with capture, and with a small force repulsed the Turks.

His efforts to interrupt the sea communications of the Egyptian forces failed, owing to the enormous disproportion of
the two squadrons in the siege and strength of the ships. As the war went on the naval power of the Greeks diminished, partly owing to the penury of their treasury, and partly to the growth of piracy in the Eastern Mediterranean. When Mauisalz' (MgOH) 1876, the developed: olivine; not KLi[Al(OH,F)
angles India, corresponding primary dendritic siliceous such they produced. (112). other sharp

The different kinds of mica vary from perfectly colourless and transparent—as in muscovite—through shades of yellow, green, red and brown to black and opaque—such as in lepidolame; the former have a pearly lustre and the latter a submetallic lustre on the cleavage surfaces. Sheets of mica very often show coloured rings and bands (Newton's rings), due to the interference of light at the surfaces of internal cleavage cracks. The spec. grav. varies between 2.7 and 3.1 in the different species. The hardness is 2–3; smooth cleavage surfaces can be just scratched with the finger-nail. The micas are bad conductors of heat and electricity, and it is on these properties that many of their technical applications depend.

Inclusions of other minerals are frequently to be observed in mica. Flattened crystals of garnet, films of quartz, and needles of tourmaline are not uncommon. Cleavage sheets are frequently disfigured and rendered of little value by brown, red or black spots and stains, often with a dendritic arrangement of iron oxides. Minute acicular inclusions, probably of rutile, arranged parallel to the rays of the percussion figure, give rise to the phenomenon of the candle-flame or spot of light viewed through a cleavage sheet of such mica appears as a six-rayed star.

**Chemical Composition.**—The micas are extremely complex and variable in composition. They are silicates, usually orthosilicates, of aluminium together with alkalis (potassium, sodium, lithium, rarely rubidium and caesium), basic hydrogen, and, in some species magnesium, ferrous and ferric iron, rarely chromium, manganese and barium. Fluorine is also often an essential constituent, and titanium is sometimes present.

The composition of mica is given by the following formulae, some of which are only approximate. It will be seen that they may be divided into two groups—alkalimicas and the magnesium micas which correspond roughly with the division into light and dark micas.

Muscovite  
\[ H_2KAl_3(SiO_4)_2 \]
Paragonite  
\[ H_2NaAl_3(SiO_4)_2 \]
Lepidolite  
\[ KLi[Al(OH,F)F]Al_2(SiO_4)_3 \]
Zinnwaldite  
\[ (K,Li)[Al(OH,F)F]FeAl_2(SiO_4)_3 \]
Biotite  
\[ (H,K)Mg_3Fe_3(Al,F)Si_3O_10 \]
Phlogopite  
\[ H_2K,3Mg[Al,MgAl_2Si_3O_10] \]

The water which is present in muscovite to the extent of 4 to 6%, and rather less in the other species, is expelled only at a high temperature; the water is therefore water of substitution, existing as basic hydrogen or as hydroxyl replacing fluorine.

Roscoelite is a mica in which the aluminium is largely replaced by vanadium (V-OH 30%) it occurs as brownish-green scaly aggregates, closely associated with gold in California, Colorado and Western Australia.

**Artificially formed crystals of the various species of mica have been observed in furnace-slags and in smelting fusions.**

**Occurrence.**—Mica occurs as a primary and essential constituent—aggregates of almost all kinds; it is also a common product of alteration of many mineral silicates, both by weathering and by contact- and dynamo-metamorphic processes. In sedimentary rocks it occurs as detrital material.

Muscovite and biotite are commonly found in siliceous rocks, whilst phlogopite is characteristic of calcareous rocks. The best crystallized specimens of any mica are often found in small brilliant crystals of biotite, with sharp edges and cavities in the limestones blocks ejected from Monte Somma, Vesuvius. Large sheets of muscovite, such as are of commercial value, are found only in the very coarsely crystalline pegmatites, particularly with muscovite, gneiss or mica schist. These veins consist of felspar, quartz and mica, often with smaller amounts of other crystallized minerals, such as tourmaline, beryl and garnet; they are worked for mica in India, the United
States (South Dakota, Colorado and Alberta), and Brazil (Goyaz, Bahia and Minas Geraes). The commercially valuable micas of Canada and Ceylon are mainly phlogopite, (q.v.), which has a rather different mode of occurrence. The mica produced in India is practically all muscovite. The principal mining districts are those of Hazari-bigh in Bengal and Nellore in Madras; in the former district the mica is usually better graded than in the latter it is more often ground. In the Jukári mine, Nellore, "books" of mica measuring 10 ft. across, and up to 15 ft. across the folia have been found, and rectangular sheets measuring 36 by 24 in. and free from cracks and flaws are sold commercially.

Uses.—On account of its transparency and its resistance to fire and sudden changes of temperature, mica has been much used for the windows of stoves and lanterns, for the ppop-heals of furnaces, and the chimneys of lamps and gas-burners. At one time it was used for window panes of houses and the port-holes of Russian men-of-war, being commonly known as "Muscovy glass." Spangles of mica are much used for decorative purposes of various kinds, and the mineral was formerly known as glacies Mariae (Ger., Framenlos) because of its use for decorating statues of the Virgin. The lapides speculaires of Pliny, scattered over the Circus Maximus to produce a shining whiteness, was probably mica. Large quantities of ground mica are used in the manufacture of wall-paper, and to produce a frosted effect on toys, stage scenery, &c. Powdered mica is also used in the manufacture of paints and paper, as a lubricant, and as an absorbent of nitro-glycerine and disinfectants. Sheets of mica are used as a surface for painting, especially in India; for lantern slides; for carrying photographic films; as a protective covering for pictures and historical documents; for mounting soft and collapsible natural history specimens preserved in spirit; for the vanes of anemometers; mirrors of delicate physical instruments; for various optical and many other purposes. Being a bad conductor of heat it is used for the packing and jackets of boilers and steam-pipes. Other applications depend on the strength of its resistance to acids.

The most extensive application of mica at the present day is for electrical purposes. Being a bad conductor of electricity it is of value as an insulator, and the smooth flexible sheets are much used in the construction of armatures of dynamos and in other electrical machinery. For various purposes a manufactured material known as "micantine" or "micacite cloth" is much used; this consists of small sheets of mica cemented with shellac or other insulating cement on cloth or paper.

Phlogopite and phlogopite are practically the only species used commercially, the former being the more common. Phlogopite is rarely found as colourless transparent sheets and is therefore almost exclusively used for electrical purposes. Many other uses of mica might be mentioned. The potassium it contains renders it valuable for masonry. The species lepidolite is largely used for the manufacture of lithium and rubidium salts.

Mining, Preparation and Value.—Mica mining is an industry of considerable importance, especially in India; but here the methods of mining are very primitive and wasteful. In working downwards in open quarries and in tortuous shafts and passages much of the mica is damaged, and a large amount of labour is expended in hauling waste material to the surface. Since the mica occurs in definite veins, a more satisfactory and economica1 method would be that adopted in the American heavy-mines, with a vertical shaft, cross-cuts, and levels running along the strike of the vein: the mica could then be extracted by overhead stopping, and the waste material used for filling up the worked-out excavations.

In dressing mica the "books" are split along the cleavage into sheets of the required thickness, and the sheets trimmed into rectangles with a sharp knife, shears or guillotine, stained and damaged portions being rejected. The dressed sheets are sorted according to size, transparency, colour and freedom from spots or stains. Scrap mica is ground to powder or used in the manufacture of micantine.

The price of mica varies very considerably according to the size, transparency and quality of the sheets. An average price for cut sheets of all sizes is about 45s. per lb, but for large sheets it may be as high as 35s. per lb.
no longer deals with idolatry, but with the corruption of society, and particularly of its leaders—the grasping aristocracy whose whole energies are concentrated on devouring the poor and depriving them of their little holdings, the unjust judges and priests who for the most part are mere hired conspirators. The prophecies of the great prophets who make war against every one “that putteth not into their mouth,” but are ever ready with assurances of Yahweh’s favour to their patrons, the wealthy and noble sinners that fatten on the rash excess of the people, are vividly depicted by Micah are also prominent in Isaiah’s prophecies; they were closely connected, not only with the foreign complications due to the approach of the Assyrians, but with the break-up of the old agrarian society within Israel, and with the rapid and uncontrolled aggrandisement of the nobles during those prosperous years when the conquest of Elam by Assurbanipal and the occupation of Babylon by Nebuchadnezzar placed a new trade between the Mediterranean and the Red Sea in the hands of the rulers of Judah. On the other hand the democratic tone which distinguishes Micah from Isaiah, and his announcement of the impending fall of the capital (the deliverance of which from the Assyrian appears to Isaiah as the necessary condition for the preservation of the seed of a new and better kingdom), are explained by the fact that, while Isaiah lived in the centre of affairs, Micah, a provincial prophet, sees the capital and the aristocracy entirely from the side of a man of the oppressed people, and foretells the utter ruin of both. But this ruin does not present itself to him as involving the captivity or ruin of the nation as a whole, the congregation of Yahweh remains in J ude a when the oppressors are cast out (ii. 5); Yahweh’s words are still good to them that walk uprightly: the glory of Israel is driven to take refuge in Adullam. Thus the vision of broken-down Jerusalem was the true hope of the nation, but there is no hint that it is banished from the land.

Our only evidence as to the reception of Micah’s message by his contemporaries is that afforded by Jer. xxvi. 17 seq., both directly, in the king’s condemnation on Hezekiah and the people, and indirectly, by the fact that the prophecy was incorporated with Hosea’s in a MS. remem-
bered a century afterwards. Micah resembles Amos, both in his country origin, and in his general character, which expresses itself in strong emphasis on the ethical side of religion. As the last of the four great prophets of the 8th century he undoubtedly contributed to that religious and ethical reformation whose literary monument is the Book of Deuteronomy.1

The remainder of the book bearing the name of Micah falls into two main divisions, viz. iv. v and vi. Each differs from the first division (i.-iii.) in a marked degree. The second consists mainly of prophecy of restoration including eschatological (iv. 1 seq.) and Messianic (v. 2 seq.) hopes. The third is formed of three or four apparently unrelated passages, on the spirituality of true worship (vi. 1-8), social immorality and its doom (vi. 9-16; vii. 1-6), and Israel’s future recovery from present adversity through Divine grace (vii. 7-20). It is improbable that much, if any, of these chapters can be ascribed to Micah himself,4 not only because their contents are so different from his undoubted work (i.-iii.), for which he was subsequently remembered (Jer. xxvi. 18), but because they presuppose the historic outlook of the Exile, or a later age (e.g. iv. 6 seq.; vii. 7 seq.). It is neither psychologically nor historically impossible for a prophet of

1 i. 15; the reference, however, obscure and uncertain.
2 See the Introduction to the Century Bible, “Deuteronomy and Joshua,” by H. Wheeler Robinson.
3 chs. i.-iii., which, but slightly modified recensions of the same text, and as Isa. i. is older than the prophecy of Micah, while on the other hand Mic. iv. 4 seems the natural completion of the passage, it is common to suppose that both copy an older prophecy, the last in fact being written with the help of Isaiah, and may be the quotation of a copyist suggested by ver. 5. On the other hand it has been urged that the passage belongs to a later stage of prophetic thought than the 8th century B.C. Reasons making the view the more improbable are given by Wellhausen (p. 142) and Marti (p. 281).
4 Nowack thinks that iv. 9, 10, 14 and v. 10-14 may possibly belong to Micah; Wellhausen recognizes the same possibility, without, however, being able to identify either of them. “Ach, der weise Prophet, der alle Sprache, in Eney, Bii.,” finds nothing by Micah in iv.-vii., thinks these chapters have crystallized round two central passages, viz. iv. 1-4, and vii. 1-5, whose remodelling to the first three chapters forms a second stage in the growth of the present book. More conservative views as to authorship are taken by Driver and C. A. Smith, the former suggesting, however, that the existing Book of Micah consists only of the parts of chs. ii.-iv. .

5 judgment to be also a prophet of comfort; but the internal evidence of composition and (in whole or part) later authorship must outweigh the traditional attachment of these passages to a MS. containing the work of Micah.

The sequence of thought in chs. iv. v. is really difficult, and has led some to reverse the order (e.g. iv. 11-13 stands in direct contradiction to iv. 9, 10, and indeed 12). The last two passages agree in speaking of the capture of Jerusalem, the first declares Zion inviolable, and its capture an impossible proposition. But somehow the words are written so that we resort to the violent harmonistic process of imagining that two quite distinct situations, separated by a renewal of the theocracy, are spoken of in consequence. Another difficulty lies in the words “and thou shalt come even unto Mount Zion, and no inventions of man come between Him and His people.”

The first chapter of Micah presents a very different situation from that of chs. i.-iii. or iv.-v. Yahweh appears to pleased with His people for their sins, but the sinners are no longer a careless and oppressive aristocracy buoyed up by deceptive assurances of Yahweh’s help, by prophecies of wine and strong drink; they are bowed down by a religion of terror, wearied with attempts to propitiate an angry God by countless offerings, and even by the sacrifice of the first-born. Meantime the substance of true religion—justice, charity and a humble walk with God—is forgotten, fraud and deceit reign in all classes, the works of the house of Ahab are observed (worship of foreign gods). Yahweh’s judgments are against them; the issue is nothing less than the total desolation. All these marks may be held to foreshadow mainly the evil times of Manasseh as described in 2 Kings xxi. Cp. vii. 1-6, in which the public and private corruption of a hopeless age is but vaguely referred to. “The good old days are gone to 

Micah may very well have lived into Manasseh’s reign, but the title in i. 1 does not cover a prophecy which certainly falls after Hezekiah’s death, and the style has nothing in common with the earlier part of the book. It is therefore prudent to regard the prophecy, with Ewald, as anonymous. Ewald ascribed the whole of chs. vi. vii. to one author. Wellhausen, however, remarks with justice that the thread is abruptly broken at vii. 6, and that verses 7-20 represent Zion as already fallen before the heathen and her inhabitants as plining in the darkness of captivity. The hope of Zion is in future restoration after she has patiently borne the chastisement of her sins. Then Yahweh shall arise mindful of her (as in x. 30) to the fame of Israel shall be glorified and restored, and the heathen humbled. The faith and hope which breathe in this passage have the closest affinity with the book of Lamentations and Isa. xl-xlvi. Indeed, as Marti points out (p. 259) the triple division of the book of Micah (i.-iii.; iv.; v.; vii.) corresponds with that of the book of Isaiah (i.-xxxix.; xl.-lv.; lvi.-lxxi.) in the character of the three divisions (judgment; coming restoration; prayer for help in adversity) respectively, and in the fact that the first alone gives us pre-exilic writing in the actual words of the prophet to whom the whole book is ascribed. In both cases, it need hardly be added, that deeper spiritual values of the later passages ought in no way

1 Regarded by Stade (Z. A. T. W., 1903, p. 164 seq.) as an independent psalm.
to suffer prejudice from critical conditions as to their date and authorship.

LITERATURE.—The chief modern commentaries are those of Noetling (Die Kleinen Propheten, 1897; 2nd ed., 1904) and Marti (Doodkatpropheten, 1904), where detailed references to the older literature may be found; cf. Wellhausen, Die Kleinen Propheten (3rd ed., 1898); reference may also be made to Cheyne and Keil in the Cambridge Bible, 1882; 2nd ed., 1895), and to G. A. Smith ("The Book of the Twelve," vol. i., in I Expounder’s Bible, 1896); also to the articles on "Micah" by Neumann in Herzog’s Realency., and by Cheyne in the Ency. Bibl. (1902), iii. c. 360-374, the latter incorporating most of the original article (Ency. Brit. 9th ed.) by W. Robertson Smith, which was (as is generally) revised above. For a review of recent criticisms see Cheyne, introduction to W. R. Smith’s The Prophets of Israel, 2nd ed., pp. xxviii.-xxxvii.; also Ency. Bib. loc. cit. J. M. P. Smith discusses The Strophic Structure of the Book of Micah in vol. 3 ofed., and Semitic Studies: the Literary of W. R. Harper (Chicago, 1908).

(W. R. S.; H. W. R. *)

MICAH, in the Bible, a man of the hill-country of Ephraim whose history enters into that of the foundation of the Israelite sanctuary at Dan (Judges xvii. seq.). He had stolen from his mother eleven hundred pieces of silver (for the number cf. Judges xvi. 3), and when she uttered a curse upon the unknown thief he restored the money and she consecrated it to Yahweh. A carved image was set up in the temple temple with an ephod and teraphim (objects used in divination, cf. Gen. xxxi. 19, 30; Hos. iii. 4). He employed one of his sons to serve as priest, but when a Levite from Bethhchom came to him and gladly installed him as “father and priest.” When the tribe of Dan subsequently sought new territory and sent men to search for a suitable district they passed by Micah’s house, recognized the Levite and requested an oracle from him. When, later, they migrated, they despoiled the sacred place and carried off the gods and priest to their new home at Lehi.

MICA-SCHIST, in petrology, a rock composed essentially of mica and quartz, and having a thin parallel-banded or foliated structure, with lamellae rich in mica alternating with others which are principally quartz. They split readily along the micaceous films, and have smooth or slightly uneven surfaces covered with lustrous plates of muscovite or biotite; the quartzose lamellae are often visible only when the specimens are looked at edgewise. Mica-schists are very common in regions of Archean rocks accompanying gneisses, crystalline limestones and other schists. Some flat bands of mica in schists are crumpled or contorted with undulating foliation. Occasionally the quartz forms elliptical lenticles or “eyes.” In some cases mica comprises nearly the whole of the rock, in others quartz preponderates so that they approach quartz-schists and quartzites.

The mica may be muscovite or biotite; both are often present, while garnet or andalusite or chlorite or chrome-mica are not so common. In addition to quartz there may be a small amount of feldspar, usually albite. A great number of accessory minerals are known in mica-schists, and when these are conspicuous or important they may be regarded as consisting special varieties receiving distinctive names. Garnet, in rounded red crystals, not uncommonly idiomorphic, is the most frequent. Brown staurolite, pinkish andalusite, and grey or blue kyanite occur in some kinds of mica-schist, separately or together. The white mica-schist of the Swiss Alps contains kyanite and staurolite. Graphite (or graphoid) is also a very frequent ingredient of these rocks, giving them a leaden grey colour and causing them to soil the fingers when handled. In some mica-schists there is much calcite (calc-mica-schist); and hornblende, scapolite and augite are often seen in rocks of this sort. Tourmaline occurs, sometimes in large black prisms but more commonly in minute crystals visible only in microscopic sections. Rutile in tiny prisms, ilmenite and hematite in black or brown scales, zircon, apatite, granules of epidote or zoisite chlorite, chloritoid and pyrophyllite, or less frequency in the rocks of this group.

Mica-schists are in nearly all cases of metamorphic rocks which have been recrystallized and have obtained a schistose structure during the process. This can be proved by their chemical composition, which, with the exception of the iron minerals, is the same as that of the original rocks, though sometimes in some districts it is possible to trace every gradation from a slate (or gneiss) to a mica-schist, the intermediate stages being represented by a gneissoid schist (gneiss) which consist of quartz, muscovite and chlorite, and are neither crystalline nor so well foliated as the schists. In a few places, e.g. Bergen in Norway, fossils have been found in mica-schists. The association of quartzites and quartz-schists, graphite-schists and crystalline limestones with mica-schists in the field is explained by the fact that all these rocks are altered sediments, viz. sandstones, carbonates and slate.

Under the microscope the appearance presented by mica-schists differs according to whether the rock is cut parallel to or across the planes of foliation. In the latter case thin alternating bands comprising quartz, muscovite, chlorite and graphite will be seen, separated by thin layers of mica. In the former case the thin bands are not visible and the structure is that of a slate. In some cases andalusite and kyanite are well developed and the rock is then called an andalusite-kyanite schist (p. 359) or an andalusite-kyanite schist. These rocks are usually of recent origin, and are very commonly developed in the contact zone of a intrusive igneous body.

The mica-schists are of great importance in the engineering industry. The plates of muscovite, which are always present, are formed into mica paper or mica cloth for the insulation of electrical apparatus. In some districts it is possible to trace every gradation from a slate (or gneiss) to a mica-schist, the intermediate stages being represented by a gneissoid schist which consists of quartz, muscovite and chlorite, and are neither crystalline nor so well foliated as the schists. In a few places, e.g. Bergen in Norway, fossils have been found in mica-schists. MICHAEL (1596–1643), tsar of Russia, was the first tsar of the house of Romanov, being the son of Theodore Nekitich Romanov, afterwards the Patriarch Philaret (q.v.), and Xenia Chestovaya, afterwards the nun Martha. He was elected unanimously tsar of Russia by a national assembly on the 21st of February 1613, but not till the 24th of March did the delegates of the council discover the young tsar and his mother at the Ipatievsky monastery near Kostroma. At first Martha protested that her son was too young and tender for so difficult an office in such troublesome times. At the last moment, however, Michael consented to accept the throne, but not till the weeping boyars had solemnly declared that if he persisted in his refusal they would hold him responsible to God for the utter destruction of Muscovy. In so dilapidated a condition was the capital at this time that Michael had to wait for several weeks at the Troitsa monastery, 75 m. off, before decent accommodation could be provided for him at Moscow. He was crowned on the 22d of July. The first care of the new tsar was to clear the land of the robbers that infested it. Sweden and Poland were then got rid of respectively by the peace of Stolbova (March 10, 1617) and the truce of Deulina (Feb. 13, 1619). The most important result of the truce of Deulina was the return from exile of the tsar’s father, who henceforth took over the government till his death in October 1633, Michael occupying quite a subordinate position. He was a gentle and pious prince who gave little trouble to any one and effaced himself behind his counsellors. Fortunately for him they were relatively honest and capable men. Michael’s failure to wed his daughtergirlfriend Theodora, the daughter of the Patriarch Philaret, was due partly to the refusal of the latter to accept orthodoxy, so deeply afflicting him as to contribute to bring about his death on the 12th of July 1645.

See R. Nisbet Bain, The First Romanovs (Lon., 1905). (R. N. B.)

MICHAEL, the name of nine East-Roman emperors.

MICHAEL I. RHIANGABAS (d. 815), an obscure nobleman who had married Procopia, the daughter of Nicephorus I., and been made master of the palace. He was made emperor in a revolution against his brother-in-law, Stauracius (811).

Michael II., called PSelles, “the stammerer,” emperor 820–829, was native of Anazarbus in Phrygia, where he began life as a shepherd, but rose by his talents to the rank of general. He had favoured the enthronement of his old companion in arms Leo the Armenian (813), but, detected in a conspiracy against that emperor, had been sentenced to death in December 820; his partisans, however, succeeded in assassinating Leo and calling Michael from the prison to the throne. The principal features of his reign were a struggle against his brother general, Thomas, who aimed at the throne (822–824); the conquest of Crete by the Saracens in 823; and the beginning of their attacks upon Sicily (827). In spite of his iconoclastic sympathies, he endeavoured to conciliate the image-worshippers, but incurred the wrath of the monks by entering into a second marriage with Euphrosyne, daughter of Constantine VI., who had previously taken the veil.

Michael III. (839–867), “the drunkard,” was grandson of Michael II., and succeeded his father Theophillus when three years old (842). During his minority the empire was governed by his mother Theodora, who in spite of several defeats inflicted upon her generals maintained the frontiers against the Saracens of Bagdad and Crete. The regent displayed her religious zeal by restoring image-worship (842) and persecuting the Paulician heretics, but she entirely neglected the education of her son. As a result Michael grew up a debauchee, and fell under the sway of his uncle Bardas, who induced him to banish Theodora to a convent and practically assumed the chief control (857). Bardas justified this usurpation by introducing various internal reforms; in the wars of the period Michael himself took a more active part. During a conflict with the Saracens of the Euphrates (856–63), the emperor sustained a personal defeat (860), which was retrieved by a great victory on the part of his uncle Petronas (861). In 862 Michael and Bardas invaded Bulgaria and secured the conversion of the king to Christianity. On sea the empire suffered under the ravages of the Cretan corsairs; and in 865 the first pillaging expedition of the Russians endangered the Bosporus. In 867 Michael was assassinated by Basil the Macedonian, a former groom, who had overthrown the influence of Bardas and in 866 been associated in the Empire.

Michael IV. (d. 1041), “the Paphlogonian,” owed his elevation to Zoe, daughter of Constantine VIII., who was the wife of Romanus III., but becoming enamoured of Michael, her chamberlain, poisoned her husband and married her attendant (1034). Michael, however, being of a weak character and subject to epileptic fits, left the government in the hands of his brother, John the Eunuch, who had been first minister of Constantine and Romanus. John’s reforms of the army and financial system revived for a while the strength of the Empire, which held its own successfully against its foreign enemies. On the eastern frontier the important post of Edessa was relieved after a prolonged siege. The western Saracens were almost driven out of Sicily by George Maniakes (1038–40); but an expedition against the Italian Normans suffered several defeats, and after the recall of Maniakes most of the Sicilian conquests were lost (1041). In the north the Serbs achieved a successful revolt (1040), but a dangerous rising by the Bulgarians and Slavs which threatened the cities of Thrace and Macedonia was repressed by a triumphant campaign which the decrepit emperor undertook in person shortly before his death (1041).

Michael V. CALYPHATES, or “the caulker,” nephew and successor of the preceding, surnamed after the early occupation of his father. He owed his elevation (Dec. 1041) to his uncle John, whom along with Zoe he almost immediately banished; this led to a popular tumult in consequence of which he was deposed after a brief reign of four months, and relegated to a monastery. His unpopularity seems largely due to his attempts at administrative reform, which were strongly resented by the dominant classes.

Michael VI., “the warlike,” was already an old man when chosen by the empress Theodora as her successor shortly before her death in 1056. He was unable to check the disaffection of the feudal aristocracy, who combined with an officer named Bardas Phokas to depose him. After a successful battle in Phrygia, the rebels had no difficulty in dethroning Michael (1057), who spent the rest of his life in a monastery.

Michael VII. Ducas, or PARAPINES, was the eldest son of Constantine X. Ducas. After a joint reign with his brothers, Andronicus I. and Constantine XI. (1067–1071), he was made sole emperor through his uncle John Ducas. The feebleness of Michael, whose chief interest lay in trifling academic pursuits, and the avarice of his ministers, was disastrous to the empire. As the result of anarchy in the army, the Byzantines lost their last possessions in Italy (1071), and were forced to cede a large strip of Asia Minor which they had held since the brief period of Seljuk Turks (1074). These misfortunes, which were but partially retrieved by the suppression of a Bulgarian revolt (1073), caused widespread dissatisfaction. In 1078 two generals, Nicephorus Bryennius and Nicephorus Botaniates, simultaneously revolted. Michael resigned the throne with hardly a struggle and retired into a monastery. His nickname Parapinenes (“starver”) was due to his causing the price of wheat to rise.

Michael VIII. PALAEOLOGUS (1254–1328) was the son of Andronicus Palaeologus Comnenus and Irene Angels, the granddaughter of Alexius Angelus, emperor of Constantinople. At an early age he rose to distinction, and ultimately became
commander of the French mercenaries in the employment of the emperors of Nicaea. A few days after the death of Theodore Lascaris II. in 1259, Michael, by the assassination of Muzale (which he is believed but not proved to have encouraged) became joint-guardian with the patriarch Arsenius of the young emperor, John Lascaris, then a lad of eight years. Afterwards invested with the title of "despot," he was finally proclaimed joint-emperor and crowned alone at Nicaea on the 1st of January 1260. In July 1261, Michael, who had attacked Constantinople with the help of the Genoese, conquered the town through his general Statopoulo. He thereupon had John Lascaris blinded and banished. For this last act he was excommunicated by Arsenius, and the ban was not removed until six years afterwards (1268) on the accession of a new patriarch. In 1263 and 1264 respectively, Michael, with the help of Urban IV., concluded peace with Villehardouin, prince of Achaias, and Michael, despot of Epirus, who had previously been invited by the pope to attack him, but had been decisively beaten at Pelagonia in Thessaly (1259); Villehardouin was obliged to cede Mistra, Monemvasia and Maira in the Morea. Subsequently Michael was involved in wars with the Genoese and Venetians, whose influence in Constantinople he sought to diminish by maintaining the balance of strength between them. In the case of Charles of Sicily, aided by John of Thessaly, made war on the alleged purpose of restoring Baldwin to the throne of Constantinople, and pressed Michael so hard that he consented to send deputies to the council of Lyons (1274) and there accept the papal supremacy. The union thus brought about between the two Churches was, however, extremely distasteful to the Greeks, and the persecution of his "schismatic" subjects to which the emperor was compelled to resort weakened his power so much that Martin IV. was tempted to enter into alliance with Charles of Anjou and the Venetians for the purpose of reconquering Constantinople. The invasion, however, failed, and Michael so far had his revenge in the "Sicilian Vespers," which he helped to bring about. He died in Thrace in December 1282. In reconstituting the Byzantine Empire Michael restored the old administration without endeavouring to correct its abuses. By debasing the coinage he hastened the decay of Byzantine commerce.

MICHAEL IX. PALAEOLOUS, was the son of Andronicus II. and was associated with him on the throne from 1259, but probably not regent until 1267. He took the field against the Turks (1261, 1268) with the Grand Catalan Company (1269), but was repeatedly defeated.

MICHAEL OBRENOVICH III. (1825-1868), Prince of Servia, was the youngest son of Prince Milosh, the founder of the Obrenovich dynasty. After the abdication of his father Michael (1840) he ascended the throne of Servia. He wished to continue the work of his father, in liberating all the Servian people, and if possible all other Balkan Christians, from direct Turkish rule. But while this programme made the Sultan hostile, it also failed to win the support of Austria, which did not wish the Western Question to be opened by the ambitious Servian. The support which his aspirations found in Russia increased Turkey's and Austria's suspicions of the prince's activity. At the same time the political situation at home was not favourable to his anti-Turkish policy. The power was in the hands of men who had forced Obrenovich I. to abdicate, and feared that Obrenovich III. might avenge his father. They thought it safer for them to replace him on the throne by a man who was not an Obrenovich, and who would be personally obliged to them for his elevation. These motives were at the bottom of the revolt, started and led by Vuchich in August 1842, the outcome of which was that Prince Michael left the country and that his cœurny, Alexander Karageorgevich, was elected Prince of Servia. As an exile Prince Michael lived principally in Vienna, improving his education by studies and travels, and frequently visiting England. He constantly refused to agree to suggestions for his restoration by forcible means. His device was Tempus et meum jus, "Time and my right." He supported Servian authors and artists, and wrote himself a book in defence of his father Milosh against the attacks of Cyprian Robert. He wrote poetry too, and some of his songs, set to beautiful music, were very popular amongst the Servians. He married in 1856 the beautiful Julia, Countess Hunyadi.

In 1858 the Servians, having dethroned Prince Karageorgevich, recalled Michael's father Milosh Obrenovich I. Michael returned to Servia and on his death (1859) ascended the throne for the second time. His proclamation "that henceforth the law is the highest will in Servia," opened a new era of strict legality and at the same time of entire emancipation from foreign influences, and more especially from Turkey's interference with the internal affairs of Servia. The old constitution, granted to Servia by the sultan as the suzerain and the tsar as the protector of Servia as far back as 1839, was discarded and replaced by one which limited the power of the oligarchic senate and gave a certain share in legislation to the "Narodna Skupisha." As such a body, it was a beginning of the national army and increased the regular army. Reference in all branches of public administration were introduced, and Servia, until then a half-oriental and half-patriarchial state, was resolutely led to become a civilized country in a European sense. When in 1862 the Turkish garrison bombarded the town of Belgrade from its citadel, Prince Michael, supported by the European diplomacy, succeeded in obtaining evacuation of some of the smaller forts in Servia, but the strong fortress of Belgrade still remained garrisoned by the Turkish troops. Prince Michael now made vigorous political and military preparations for war against Turkey. He made secret arrangements with the Bulgarian, Bosnian and Albanian leaders, an alliance with Montenegro and an understanding with Greece, with the object that they should all rise if Servia declared war on Turkey. He even succeeded in obtaining Austria's promise, that it would observe an attitude of friendly neutrality and would have nothing against an eventual annexation of the largest part of Bosnia to Servia, and he secured to himself the sympathies of Napoleon III. and his government. In the beginning of 1867 he formally asked the Porte to withdraw the Turkish garrisons from the forts of Belgrade, as well as from other two of minor importance (Shabets and Smederevo (Serbia)). For some time the chances were that a war would take place that spring (1867) between Servia and Turkey, but peace was kept by the action of Great Britain, who advised the sultan to withdraw the Turkish garrisons from the Servian fortresses; and this advice, backed by Russia, France and Austria, prevailed at last with the sultan. On the 26th of April 1867 the fortresses were delivered over to Prince Michael, who shortly afterwards went to Constantinople to thank the sultan personally.

Prince Michael's policy had triumphed. But his success was short-lived. A group of young men, mostly educated in France and Germany, now started a liberal movement under the leadership of Yovon Ristich (or Ristitch). They wanted a more liberal constitution than that which Prince Michael had given; and this movement tended to qualify his popularity. Meanwhile the prince contemplated divorce from his wife Princess Julia, by whom he had no children, and marriage with the daughter of his cousin Madame Arika Constantinovich; and the adherents of the exiled Karageorgevich dynasty were alarmed at the prospect of his eventually having legal heirs to the throne. A former private secretary to Prince Alexander Karageorgevich, and two of his prince's brothers-in-law, formed a conspiracy, which resulted in the brutal assassination of Prince Michael on the 26th of May (June 10 (O.S.), 1868), whilst he was walking in the park of Koshutnyak, a few miles distant from Belgrade.

(C. M.)

MICHAELIS, JOHANN DAVID (1717-1791), German biblical scholar and teacher, a member of a family which had the chief part in maintaining that solid discipline in Hebrew and the
cognate languages which distinguished the university of Halle in the period of Pietism. Johann Heinrich Michaelis (1668-1738) was the chief director of A. H. Francke's Collegium orientale theologicum, a practical school of biblical and oriental philology then quite unique, and the author of an annotated Hebrew Bible and various exegetical works of reputation, especially the Adnotationes ulteriores in hagiographis (1720). In his chief publications J. H. Michaelis had as fellow-worker his sister’s son Christian Benedikt Michaelis (1680-1762), the father of Johann David, who was likewise influential as professor at Halle, and a sound scholar, especially in Syriae. J. D. Michaelis was trained for academical life under his father’s eye. At Halle he was influenced, especially in philosophy, by Sigmund J. Baumgarten (1762-1757), the link between the old Pietism and J. S. Semler, while he cultivated his strong taste for history under Chancellor Ludwig. In 1739-1740 he qualified as university lecturer. One of his dissertations was a defence of the antiquity and divine authority of the vowel-points in Hebrew. His scholarship still moved in the old tradition, and he was also much exercised by religious scruples, the conflict of an independent mind with that submission to authority at the expense of reason encouraged by the Lutheranism in which he had been trained. A visit to England in 1741-1742 lifted him out of the narrow groove of his earlier education. In passing through Holland he made the acquaintance of Albert Schultens (1686-1759), whose influence on his philological views became all-powerful a few years later. At Halle Michaelis felt himself out of place, and in 1745 he gladly accepted an invitation to conduct a grammar in Munich. In 1746 he became professor extraordinarius, in 1750 ordinarius, and in Göttingen he remained till his death in 1791.

His intellect was active in many directions; universal learning indeed was perhaps one of his foibles. Literature—modern as well as ancient—occupied his attention; one of his works was a translation of four parts of Clarissa; and translations of some of the then current English paraphrases on biblical books manifested his sympathy with a school which, if not very learned, attracted him by its freer air. His oriental studies were reshaped by diligent perusal of the works of Schultens; for the Halle school, with all its learning, had no conception of the principles on which a fruitful connexion between Biblical and Oriental learning could be established. His linguistic work indeed was always hampered by the lack of manuscript material, which is felt in his philological writings, e.g. in his valuable Suplementa to the Hebrew lexicons (1754-1792). He could not become such an Arabist as J. J. Reiske (1716-1774); and, though for many years the most famous teacher of Semitic languages in Europe, he had little of the higher philological faculty, and neither his grammatical nor his critical work has left a permanent mark, with the exception perhaps of his text-critical studies on the Peshatta. His tastes were all for such studies as history, antiquities, and especially geography and natural science. He had in fact started his university course as a medicænæ cælor, and in his autobiography he half regrets that he did not choose the medical profession. In geography he found a field hardly touched since Samuel Bochart, in whose footsteps he followed in the Spicilegium geographiæ hebraeorum externe post Bochartum (1760-1780); and to his impulse we owe the famous Eastern expedition conducted by Carsten Niebuhr. In spite of his doctrinal writings—which at the time made little noise, so that his Commentarius dogmaticus (1760) was unimpressed by Wash. and the knighthood of the North Star was afterwards given him in reparation—it was the natural side of the Bible that really attracted him, and no man did more to introduce the modern method of studying Hebrew antiquity as an integral part of ancient Eastern life.

The personal character of Michaelis can be read between the lines of his autobiography with the aid of the other materials collected by J. M. Hassencamp (1743-1797) the editor (J. D. Michaelis Lebensbeschreibung, &c., 1793). The same volume contains a full list of his works. Besides those already mentioned it is sufficient to refer to his New Testament Introduction (the first edition, 1750, preceded the full development of his powers, and is a very different work of his later editions), his reprint of Robert Lowth’s Prælectiones with important additions (1758-1762), his German translation of the Bible with notes (1733-1792), his Orientallische und exegetische Bibliothek (1773-1785) and Neue O. E. Br. (1780-1791), his Haßeltisches Recht (1759-1762), the 2nd edition of E. Castel’s Lexicon syriacum (1778-1788). His Literarischer Briefwechsel (1794-1796) contains much that is interesting for the history of learning in his time.

MICHAUD, JOSEPH FRANÇOIS (1767-1830), French historian and publicist, was born of an old family on the 10th of June 1767, at Albens, Savoy, was educated at Bourg-en-Bresse, and afterwards engaged in literary work at Lyons, where the events of 1789 first called out the strong dislike to revolutionary principles which manifested itself throughout the rest of his life. In 1790 he went to Paris, where, not without danger, he took part in editing several royalist journals. In 1796 he became editor of La Quotidienne, for his connexion with which he was arrested after the 13th of Vendémiaire; he succeeded in escaping his captors, but was sentenced to death par contumace by the military council. Having resumed the editorship of his newspaper on the establishment of the Directory, he was again proscribed on the 18th of Fructidor, but at the close of two years returned to Paris in consequence of the Directory having superseded the Directory. His Bourbon sympathies led to a brief imprisonment in 1802, and on his release he for the time abandoned journalism, and began to write or edit books. Along with his brother and two colleagues he published in 1806 a Biographie moderne, ou dictionnaire des hommes qui se sont fait un nom en Europe depuis 1750, the earliest work of its kind; and in 1811 appeared the first volume of his Histoire des croisades and also the first volume of his Biographie universelle. In 1813 he succeeded the last editor of La Quotidienne, and in the same year was elected Academician. In 1815 his brochure entitled Histoire des guerres semitiques ou le dernier règne de Benabarte met with extraordinary success, passing through twenty-seven editions within a very short time. His political services were now rewarded with the cross of an officer in the Legion of Honour and the modest post of king’s reader, of which last he was deprived in 1827 for having opposed Peyronnet’s “Loi d’Amour” against the freedom of the Press. In 1830-1831 he travelled in Syria and Egypt for the purpose of collecting additional materials for the Histoire des croisades; his correspondence with a fellow explorer, J. J. P. Poujoulat, consisting practically of discussions and elucidations of various points in that work, was afterwards published (Correspondance d’orient, 7 vols., 1833-1835). Like the Histoire, it is more interesting than exact. The Bibliothèque des croisades, in four volumes more, contained the “Pièces justificatives” of the Histoire. Michaud died on the 30th of September 1830, at Passy, where his home had been since 1832.

MICHAUX, ANDRÉ (1746-1802), French botanist and traveller, was born at Versailles on the 7th of March 1746. In 1779 he spent some time botanizing in England, and in 1780 he explored Auvergne, the Pyrénées and the north of Spain. In 1782 he was sent by the French government on a botanical mission to Persia. His journey began unfavourably, as he was robbed by Arabs of all his equipment except his books; but he gained influential support in Persia, having cured the shah of a dangerous illness. After two years he returned to France with a fine herbarium, and also introduced numerous Eastern plants into the botanical gardens of France. In 1785 he was sent by the French government to North America, and travelled with his son François André (1770-1853) through, Canadians, 

1 By a strange fortune of war it was the occupation of Göttingen by the French in the Seven Years’ War, and the friendly relations he formed with the officers, that procured him the Paris MS, from which he edited Abulfeda’s description of Egypt.

MICHEL, C.—MICHELANGELO

Nova Scotia and the United States. On his return to France in 1792 he was shipwrecked and lost most of his collections. In 1800 he went to Madagascar to investigate the flora of that island, and died there on the 16th of July 1803. His work as a botanist was chiefly done in the field, and he added largely to what was previously known of the botany of the East and of America.

MICHEL, CLAUDE, known as Clodion (1738-1814), French sculptor, was born on the 20th of December 1736 in Nancy. Here and probably in Lille he spent the earlier years of his life. In 1755 he came to Paris and entered the workshop of Lambert Sigsbert Adam, his maternal uncle, a clever sculptor. He remained four years in this workshop, and on the death of his uncle became a pupil of J. B. Pigalle. In 1759 he obtained the grand prize for sculpture at the Académie Royale; in 1761 he obtained the first silver medal for studies from models; and in 1762 he went to Rome. Here his activity was considerable between 1767 and 1771. Catherine II. was eager to secure his presence in St. Petersburg, but he returned to Paris.

Among his patrons, which were very numerous, were the coterie of Roi, the pension Languedoc, and the Direction générale. His works were frequently exhibited at the Salon. In 1782 he married Catherine Flore, a daughter of the sculptor Augustin Pajou, who subsequently obtained a divorce from him. The agitation caused by the Revolution drove Clodion in 1792 to Nancy, where he remained until 1798, his energies being spent in the decoration of houses. Among Clodion’s works are a statue of Montesquieu, a “Dying Cleopatra,” and a chimney-piece in the South Kensington Museum.

One of his last groups represented Homer as a beggar being driven away by fishermen (1810). On the 29th of March 1814 Clodion died in Paris, on the eve of the invasion of Paris by the allies.

Thirion’s Les Adam et Clodion (Paris, 1885) contains a list of the sculptor’s works sold between 1767 and 1884. See also A. Jacquot, Les Adam et les Michel et Clodion (Paris, 1898).

MICHEL, CLÉMENCE LOUISE (1839-1903), French anarchist, called la Vierge rge de Montmartre, was born at the château de Vroncourt (Haut-Marne) on the 27th of April 1839. Her daughter was a daughter of a serving-maid, Marianne Michel, and the son of the house, Étienne Charles Demais. She was brought up by her father’s parents, and received a liberal education. After her grandfather’s death in 1850 she was trained to teach, but her refusal to acknowledge Napoleon III. prevented her from serving in a state school. She found her way in 1866 to a school in the Montmartre quarter of Paris, where she threw herself ardently into works of charity and revolutionary politics. She became violently anti-Bonapartist, and is said to have meditated the assassination of Napoleon. During the siege of Paris she joined the ambulance service, and unflinchingly preached resistance to the Prussians. On the establishment of the Commune she joined the National Guard. She offered to shoot Thiers, and suggested the destruction of Paris by way of vengeance for its surrender. She was with the Communards who made their last stand in the cemetery of Montmartre, and was closely allied with Théodore Ferré, who was executed in November 1871. This ardent attachment was perhaps one of the sources of the exaltation which marked her career, and gave many handles to her enemies. When she was brought before the 6th court of war in December 1871 she defied her judges and defended the Commune. She was sent as a convict to New Caledonia, among her companions being Henri Rochefort, who remained her friend till the day of her death. The amnesty of 1880 found her revolutionary ardour unchanged. She travelled throughout France, preaching revolution, and in 1883 she led a Paris mob which pillaged a baker’s shop. For this she was condemned to six years’ imprisonment, but was released in 1886, at the same time as Prince Kropotkin and other prominent anarchists.

After a short period of freedom she was again arrested for making inflammatory speeches. She was soon liberated, but, hearing that her enemies hoped to intern her in a lunatic asylum, she fled to England. She returned to France in 1895, and in 1902 was back in London. She was touring France and lecturing on behalf of anarchist propaganda when she died at Marseilles on the 10th of January 1905.

Her Mémoires (Paris, 1886) contain accounts of her trials. See also La Bonne Louise (Paris, 1900), by E. Girault.

MICHEL, FRANCISSE XAVIER (1809-1887), French anti- revolutionary, was born at Lyons on the 9th of January 1809. He became known for his editions of French works of the middle ages, and the French Government, recognizing their value, sent him to England (1833) and Scotland (1837) to continue his researches there. In 1839 he was appointed professor of foreign literature in the Faculté des lettres at Bordeaux. Between 1834 and 1842 he published editions of a large number of works written between the eleventh and fourteenth centuries in French, English and Saxon, including the Roman de la rose and the Chanson de Roland.

Subsequently he published French translations of Godfrey, Stereo, Shake- speare’s “Cymbeline” and Tennyson. He died in Paris on the 19th of May 1887.

His original works include Histoire des races maudites de la France et de l’Espagne (1847); Recherches sur le commerce pendant le moyen âge (1852-1854); Les Ecossais en France et les français en Ecosse (1869); and Vie et opere de Théophile Paré (1856-1860). On the basque (1857); Histoire du commerce et de la navigation à Bordeaux (1867-1871); and, in conjunction with Edouard Fournier, Histoire des hôtelleries, cabarets, hôtels gérés (1851-1854).

MICHELANGELO (MICHELANGELO BUONARROTI) (1475-1564), the most famous of the great Florentine artists of the Renaissance, was the son of Ludovico Buonarotti, a poor gentleman of that city, and of his wife Francesca dei Neri. The Buonarroti Simon were an old and pure Florentine stock of the Guelf faction: in the days of Michelangelo’s fame a connexion of the family with the counts of Canossa was imagined and admitted on both sides, but has no foundation in fact. Ludovico was barely able to live on the income of his estate, but made it his boast that he had never stooped to add to it by mercantile or mechanical pursuits. The favour of the Medici procured him temporary employment in minor offices of state, among them that of podestà of Pisa; and in 1479 he was made Maestro di Caprese, of the painting of frescoes in the chapel of the Medici (1476). On 23rd of May 1477, at Castello di Chiusi and Caprese in the Casentino. At Caprese, on the 6th of March 1475, his second son Michelagniolo or Michelangelo was born. Immediately afterwards the family returned to Florence, and the child was put to nurse with a marble-worker’s wife of Settignano. His mother’s health had already, it would seem, begun to fail; at all events in a few years from this time, after she had borne her husband three more sons, she died. While still a young boy Michelangelo determined, in spite of his father’s opposition, to be an artist. He had sucked in the passion, as he himself used to say, with his foster-mother’s milk. After a sharp struggle his stubborn will overcame his father’s pride of gentility, and at thirteen he got himself articulated as a paid assistant in the workshop of the brothers Ghirlandaio. Domenico Ghirlandaio, bred a jeweller, had become by this time the foremost painter of Florence. In his service the young Michelangelo laid the foundations of that skill in fresco with which twenty years afterwards he confounded his detractors at Rome. He studied also, like all the Florentine artists of that age, in the Brancacci chapel, where the frescoes of Masaccio, painted some sixty years before, still held their own and here, in reply, to a taunt he had flung at a fellow-student, Torrigiano, he received the blow on the nose which disfigured him to his dying day.

Though Michelangelo’s earliest studies were directed towards painting, he was by nature and predilection much more inclined to sculpture. In that art he presently received encouragement and training under the eye of an illustrious patron, Lorenzo dei Medici. On the recommendation, it is said, of Ghirlandaio, he was transferred, before the term of his apprenticeship as
Michelangelo's stay in Rome at this time lasted five years—from the summer of 1496 till that of 1501. The interval had been one of extreme political distraction at Florence. The excitement of the French invasion, the mystic and ascetic regiment of Savonarola, the reaction which led to his overthrow, and finally the external wars and internal dissidences which preceded a new settlement, had all created an atmosphere so repulsive to art. Nevertheless Ludovico Buonarroti, who in the turmoil of the Florence war was lost and the house of the Medici fell from power, and Michelangelo, who had been repeatedly urging him to come home. A spirit of family duty and family pride was the ruling principle in all Michelangelo's conduct. During the best years of his life he submitted himself sternly and without a murmur to pinchardship and almost superhuman labour for the sake of his father and brothers, who were ever so easily ready to be fed and helped by him. Having now, after an illness, come home in 1501, Michelangelo was requested by the cardinal Francesco Piccolomini to adorn with a number of sculptured figures a shrine already begun in the cathedral of Siena in honour of the most distinguished member of his house, Pope Pius II. Four only of these figures were ever executed, and those not apparently, or only in small part, by the master's hand. A work of greater interest in Florence itself had diverted him from his engagement to his Sienese patrons. This was the execution of the famous colossal statue of David, popularly known as the Giant. It was carved out of a huge block of marble on which another sculptor, Agostino d'Antonio, had begun unsuccessfully to work forty years before, and which had been lying idle ever since. Michelangelo had here a difficult problem before him. Without much regard to the traditional treatment of the subject or the historical character of his hero, he carved out of the vast but cramped mass of material an adolescent, frowning colossal, tensely watchful and self-balanced in preparation for his great action. The result amazed every beholder by its freedom and science of execution and its victorious energy of expression. All the best artists of Florence were called in council to determine on what site it should be set up, and after much debate the terrace of the palace of the Signory was chosen, in preference to the neighbouring Loggia dei Lanzi. Here accordingly the colossal "David" of Michelangelo took, in the month of May 1504, the place which it continued to hold until 1882 it was removed for the sake of protection to a hall in the Academy of Fine Arts, where it inevitably looks crushed and cabined. Other works of sculpture belong to the same period: among them a second "David," in bronze and on a smaller scale, commissioned by the maréchal Pierre Rohan and left by the young master to be finished by Benedetto da Maiano, who was known as "Brutus" or "the great rough-hewn "St Matthew" begun but never completed for the cathedral of Florence; a "Madonna and Child" executed on the commission of a merchant of Bruges; and two unfinished bas-reliefs of the same subject.

Neither was Michelangelo idle at the same time as a painter. Leaving disputed works for the moment out of sight, he in these days at any rate painted for his and Raphael's common patron, Angelo Doni, the "Holy Family" now in the Uffizi at Florence. In the autumn of 1504, the year of the completion of the "David," he was engaged in the Florentine state's commission for a work of monumental painting on a heroic scale. Leonardo da Vinci had been for some months engaged on his great cartoon of the "Battle of Anghiari," to be painted on the wall of the great hall of the municipal council. The gonfaloniere Piero Soderini now procured for Michelangelo the commission to design a companion work. Michelangelo chose an incident at the battle of Cascina during the Pisan war of 1536, when the Florentine soldiery had been surprised by the enemy in the act of bathing. He dashed at the task with his accustomed fiery energy, and had carried a great part of the cartoon to completion when, in the early spring of 1505, he broke off the work in order to obey a call to Rome which reached him from Pope Julius II. His unfinished cartoon, in its power over the varieties and contrasts
of energetic and vitally significant action, showed how greatly Michelangelo had profited by the example of his elder rival, Leonardo, little as, personally, he yielded to Lecchi's or any other counsel or could bring himself to respond as his courtesy. The work of Michelangelo's is such for the most part comparatively treated in character. His early sculpture, showing a degree of science and perfection unequalled since the antique, has also something of the antique serenity. It bears strongly the stamp of intellectual research, but not by any means that of storm or strain. In the cartoons of the "Bathers" the qualities afterwards proverbially associated with Michelangelo—his furia, his terribilitá, the tempest and hurricane of the spirit which accompanied his unequalled technical mastery and knowledge—first fully disclosed their nature.

With Michelangelo's departure to Rome early in 1505 the first part of his artistic career may be said to end. It will be convenient here to recapitulate its principal results in sculpture and painting, both those preserved and those recorded but lost.

**SCULPTURE.**—Florence, 1489-1494. — Head of a Faun; marble; lost. Condelli describes Michelangelo's first essay in sculpture as a head of an aged faun with a front tooth knocked out, this latter point having it an afternoon he gave the Pitti Faun a mouth. The head is sometimes identified with one in the National Museum, at Florence, which however bears no marks of Michelangelo's early style and is in all probability an outgrowth of Madonnina St Peter's, Rome; marble; lost. Shakespeare's "tempest" of the word of Donatello, Florence. This base-relief, executed in imitation of the technical style of Donatello, is a genuine example of Michelangelo's early work in the Medici school under Benvenuto Cellini. It bears a surname of sterile genuine work in full relief, of probably somewhat later date than the last-mentioned. The subject occurs often in ancient sarcophagus reliefs; Michelangelo has followed the antiquity in his conception and treatment of it. In the arrangement of the subject is the same in Bologna, 1493-1495.—Statuettes of "St Petronius," "St Proculus," and a "Kneeling Angel," marble; part of the decorations of the shrine of St Dominic in the church that saint at Bologna; the style of all three much influenced by the work of Jacopo della Quercia in the same church; the attitude of the kneeling angel with the candelabrum imitated from an ancient base-relief.

**PAINTING.**—1497.—"St John the Baptist," fresco, executed for Lorenzo di Pierfrancesco de'Medici, marble; probably lost. Declared in 1875 to have been found again in the possession of Count Guiseppe Rosamini at Pisa, Vehement and prolonged discussions arose as to the authenticity of this newly-discovered S. Giovanni, and at last it was bought for the Berlin Museum, where its genuineness is still stoutly maintained. But the finicking and affected elegance of the conception denote a different temperament from Michelangelo's and probably a later date. With this figure must be given up also the restoration of an antique group of "Bacchus and Ampelus" at the Uffizi, which has been declared by no less an authority than the himself as the "Genesis of Michelangelo." —"Rembrandt Cupid," bought by the cardinal San Giorgio as an antique, marble; lost. The attempts to recognize it in certain extant copies or servile imitations of the original are quite a species of at least held mantelpiece. Rome, 1505-1507. — "Virgin lamenting the dead Christ," commissioned by the abbot de la Graole; marble, St Peter's, Rome. — "Bacchos and young Faun," commissioned by Jacopo Galli; marble, National Museum, Florence. (Of these two masterpieces of Michelangelo's youth enough has been said above.) — "Cupid," commissioned by the abbot de la Graole; marble; lost; has been commonly identified as the "Kneeling Cupid" of the Victoria and Albert Museum, but this, if by Michelangelo at all, which is not quite certain, must in all likelihood belong to a later time. Florence, 1507-1506. — Five Saints, in niches decorating the stair of Pius II., executed for the Pio-Panfilii family; niche in the cathedral of Siena. The contract for the sculptured decoration of this shrine was one of those which the pressure of other work prevented Michelangelo ever taking in hand, and the saints in niches, traditionally reputed to be his work, the St Peter alone shows any clear marks of his style; the other four were probably designed, and certainly carried out, by weaker hands. — "David" (the copy), commissioned for the city of Florence by Pietro Soderini; marble; Florence Academy. Besides what has been said above, it has only to be added that a wax model in the Casa Buonarroti, Florence, and a supporting design with a different movement of the legs, is probably Michelangelo's. — "Becket" (the sketch for a statue), commissioned by the Cathedral Chapter of London, Royal Academy. The motive of the Child-christ frightened by the flower of St John is the most playful in all Michelangelo's work; the whole drawing shows the influence of Leonardo in his gentler, as much as the cartoon of the "Bathers" shows it in his more violent, mood.

"Virgin and Child with St John," commissioned by Bartolommeo Pitti; nearly circular relief, unfinished, marble; Florence, National Museum; a more tranquil and very charming presentation. — "Madonna of the Child," commissioned by the Minio family of Bruges (known in Italy as Moscheroni), and by them presented to the church of Notre Dame in that city; group in the round, marble; church of Notre Dame, Bruges. A meditative seated Virgin with upright Child, the curve of his head being rounded in form in strong contrast with her complicated draperies. — "St Matthew": one of a set of twelve statues of Apostles commissioned by the censor sold to the Medici; marble; National Museum, Florence. Unfinished (only roughly blocked out), the other figures of the set never having been so much as begun; the contract was signed in 1503 and cancelled in 1505. There is an early drawing by Raphael from this statue.

**PAINTING.** — "Holy Family," painted for Angelo Doni; tempera, circular; Florence, Uffizi. The only perfectly well-attested panel painting of Michelangelo which exists. His love of restless and somewhat strained actions is illustrated by the gesture of the Father who kneels on the ground holding up the child on her right shoulder; his love of the nude by the introduction (wherein he follows Luca Signorelli) of some otherwise purposeless undraped figures in the background. — "Virgin and Child with Four Angels": tempera; National Gallery, London. This unfinished painting, strongly marked by the influence of Michelangelo in his work at this period, has been confidently claimed for him, but lacks his strength and mastery, and is far more probably the work of his imitator and intimate associate, Francesco Granacci. — "Cartoon of the Bathers": and lost and utterly perished. The only authentic records of it are сохранины из фрагментов the few drawings, of which one was by studi Venexiano and a certain number of sketches and studies by the master himself, chiefly at the Albertina, Vienna, the British Museum and the Louvre. The untrammelled Michelangelo leaves us to infer that many figures at Holkham Hall, well known and often engraved, seems to be a later of de facto destitute of real authority.

Michelangelo had not been long in Rome before Pope Julius devised fit employment for him. That capacious and headstrong spirit, on fire with great enterprises, had conceived the idea of a sepulchral monument to commemorate his glory when he should be dead, and to be executed according to his own plans while he was still living. He entrusted this congenial task to Michelangelo. The design being approved, the artist spent the winter of 1505-1506 at the quarries of Carrara, superintending the excavation and shipment of the necessary marbles. In the spring he returned to Rome, and when the marbles arrived fell to with all his energy at the preparations for the work. For a while the pope followed their progress eagerly, and was all kindness to the young sculptor. But presently his dispositions of the money was his to use as he pleased. Pope Julius, a friend of his, Bramante of Urbino, had been selected by Julius to carry out a new architectural scheme, commensurate with the usual vastness of his conceptions, viz., the rebuilding of St Peter's church. To the influence and the jealousy of Bramante Michelangelo attributed the unwell invitation he now received to interrupt the great work of sculpture which he had just begun in order to decorate the Sixtine chapel with frescoes. Soon, however, schemes of war and conquest interposed to divert the thoughts of Julius, not from the progress of his own monument merely, but from artistic enterprises altogether. One day Michelangelo heard him say at table to his jeweller that he meant to spend no more money on pebbles, either small or great. To add to the artist's discontent, when he went to apply in person for payments due, he was first put off from day to day, and at last actually with scant courtesy dismissed.

At this his dark mood got the mastery of him. Convinced that not his employment only but his life was threatened, he suddenly took horse and left Rome, and before the messengers of the pope could overtake him was safe on Florentine territory. Michelangelo's flight took place in April 1506. Once among his own people, he turned to a dead ear from Rome for his return, and stayed throughout the summer at Florence, where he occupied we are not distinctly informed, but apparently, among other things, on the continuation of his great battle cartoon.

During the same summer Julius planned and executed the victorious military campaign which ended with his unopposed entry at the head of his army into Bologna. Thither, under strict safe-conduct and promises of renewed favour, Michelangelo...
as far as Bologna. This was between September 1510, by which time the whole of the great series of subjects along the centre of the vault were completed, and January 1511, when the master set to work again and began filling the complicated lateral spaces of his decorative scheme.

The main field of the Sixtine ceiling—in form a depressed barrel vault—was filled in Michelangelo’s scheme into four larger, alternating with five smaller, compartments. The subjects depicted in them: (1) the division of the light from the darkness; (2) the creation of sun, moon and stars; (3) the creation of man and woman; (4) the fall of man; (5) the temptation of Adam and Eve; (6) the expulsion; (7) the sacrifice of Noah; (8) the deluge; (9) the drunkenness of Noah. The figures in the last three of these scenes are on a smaller scale than those in the first six. In the central compartment of the vault, these encroachments of the architectural framework with its seated pairs of supporters, commonly known as “Slaves” or “Atlases.” Flanks of the vault and the walls on either side, are scenes of prophets and sibyls alternately; two other prophets are introduced at each extremity of the series—making seven prophets and five sibyls in all. In the triangles to right and left of the prophets at the two extremities are the death of Goliath, the death of Holophernes, the brazen serpent and the punishment of Haman. In the upper lunettes, the windows are groups of the ancestors of Christ, their names designated by inscription. In the lower triangles above them (between the prophets and sibyls) other kindred groups crowded or sitting. These last are all shown in similar groups by Raphael’s simple, confident design, heightened but not falsified by the artist’s genius, and rising into majestic significance from roots deep in daily human nature. The work represents all the powers of Michelangelo at their best. During the whole of the undertaking the artist, living at Rome, concentrated himself upon the exclusive delineation of the human form and face at their highest power. His imagination has conceived, and his knowledge and skill enabled him to realize, attitudes and combinations of unmatched variety, grace, and grandeur, and countenances of unmatched expressiveness and power. But he has not trusted, as he came later to trust, to science and acquired knowledge merely; neither did his persons, so far as the sculptor afterwards, transcend human possibility or leave the facts of actual life behind them. The profoundest knowledge and the most searching analysis serve to give his inspiration and sustain all this subtlety; the sublimity, moreover, is combined with the noblest elements of grace and even of tenderness. As for the intellectual meanings of his vast design, over and above those which reveal themselves at a first glance or by a bare description, they are from the nature of the case inexhaustible, and can never be perfectly defined. Whatever the soul of this great Florentine, the spiritual heir of Dante, with the Christianity of the middle ages never seen in his mind, but expanded and transcendentalized, did the knowledge and love of Plato,—whatever the soul of such a man, full of suppressed tenderness and righteous indignation, and of the sublime contumely of a tyrant's death. More than once Michelangelo has expressed or shadowed forth in this great and significant scheme of paintings. The powers of the artist seem to have expanded with the progress of his work. He seems to have begun (as he says) in the vault, and then to have ascended step by step, by what is chronologically the last subject of the series, the drunkenness of Noah, and to have worked backwards, increasing the scale of his figures for their better effect from the fourth subject (the Temptation and Expulsion), and rising in ascending scale of majesty through the successive acts of creation from the last to the first.

The Sixtine chapel was no sooner completed than Michelangelo resumed work upon the marbles for the monument of Julius. But four months only had passed when Julius died. His heirs immediately entered (in the summer of 1513) into a new contract with Michelangelo for the execution of the monument on a reduced scale. What the precise nature and extent of the original design had been we do not know; all that we do know is, that it was to be detached from the wall, and to stand four-square and free—a thing hitherto unknown in Renaissance sepulchral architecture—in one of the chapels of St Peter’s. But the new design was extensive and magnificent enough. It was to consist of a great three-sided structure, two courses high, projecting from the church wall, and decorated on its three unattached sides with statues. On the upper course was to be placed the colossal recumbent figures of the pope, with a vision of the Virgin and Child above him, angels mourning at the sides, and prophetic and allegoric personages. The lower course was to be enriched with twenty-four figures in niches and on projecting pedestals: in the niches, Victories; in front of terminal pilasters between them,
slaves or captives denoting, it would seem, either captor or provinces or arts and sciences in bondage after their patron's death. A much injured and manuscriptable sketch by the master at Bologna, a copy of the same by Sacchetti, are supplied to show the design at this stage of its reduction. The entire work was to be completed in nine years' time. During the next three years, it would seem, Michelangelo brought to completion three at least of the promised figures, for which the blocks had reached Rome from Carrara as early as July 1508; and they are among the most famous of all existing works of the sculptor's art—namely, the "Moses," now in the church of S. Pietro in Vincoli at Rome and the two "Slaves" at the Louvre.

The "Moses," originally intended for one of the angles of the upper course, is now placed at the level of the eye, in the centre of the principal face of the monument as it was at last finished, on a deplorably reduced and altered scale, by Michelangelo and his assistants in his old age. The prophet, supposed to have just come down from Mount Sinai and found the Israelites worshipping the golden calf, sits, heavily bearded and draped, with only his right arm bare, his foot left drawn back, his head raised and turned to the left, his hands laid on his lap and his right grasping the tables of the law—an incarnation of majestic indignation and menace. The work, except in one or two places, is of the utmost finish, and the statue is one of the most of the prophets and Sixtine ceiling lions in marble. The "Slaves" at the Louvre are youthful male figures of equally perfect execution, nude but for the band which passes over the breast of one and the right leg of the other. One, with his left hand raised to his head and his right pressed to his bosom, his eyes almost closed, seems succumbing to the agonies of death; the other, with his arms bound behind his back, looks upward still hopelessly struggling. All three of these figures were finished between 1513 and 1516.

By 1516 Michelangelo's evil star was again in the ascendant. Julius II. had been succeeded on the papal throne by Cardinal Giovanni de' Medici under the title of Leo X. The Medici, too, had about the same time by force and fraud re-established their sway in Florence, overthrowing the free institutions that had prevailed there since the days of Savonarola. Now, on the one hand, this family were the hereditary friends and patrons of Michelangelo; on the other hand he was a patriotic son of republican Florence; so that henceforward his personal allegiance and his political sympathies were in conflict. Over much of his art, as has been thought, the pain and perplexity of this conflict have cast their shadow. For the present it seems to him of the rise to power of the Medici was a fresh interruption of his cherished work on the tomb of Julius. Leo X. and his kin were full of a vast new scheme for the enrichment and adornment of the façade of their own family church of San Lorenzo in Florence. Michelangelo, carried away by the idea and forgetful of his other still great and onerous task, offered his services for the new façade. They were eagerly accepted, although for a moment the idea had been entertained of entrusting the work to Leonardo da Vinci. The heirs of Julius on their part showed an accommodating temper, and at the request of Leo allowed their three-years-old contract to be cancelled in favour of another, whereby the scale and sculptured decorations of the Julian monument were again to be reduced by nearly a half. Michelangelo soon produced for the San Lorenzo façade a design of combined sculpture and architecture as splendid and ambitious in its way as had been that for the original monument of Julius. The contract was signed in January 1518, and the artist went to Carrara to superintend the excavation of the marbles.

Michelangelo was now in his forty-fourth year. Though half his life was yet to come, yet its best days had, as it proved, been spent. All the hindrances which he had encountered hitherto were as nothing to those which began to beset him now. For the supply of materials for the façade of San Lorenzo he had set a firm of masons to work, and had himself, it seems, entered into a kind of partnership with them, at Carrara, where he knew the quarries well, and where the industry was hereditary and well understood. When all went well in progress there under his own eye, reasons of state induced the Medici and the Florentine magistracy to bid him resort instead to certain new quarries at Pietrasanta, near Seravezza in the territory of Florence. Hither, to the disgust of his old clients at Carrara and to his own, Michelangelo accordingly had to transfer the scene of his labours. Presently he found himself so impeded and enraged by the mechanical difficulties of raising and transporting the marbles, and by the disloyalty and incompetence of those with whom he had to deal, that he was fain to throw up the commission altogether.

The contracts for the façade of San Lorenzo were rescinded in March 1518, and the whole magnificent scheme came to nothing. Michelangelo then returned to Florence, and the final result of work poured in on him from many quarters. The king of France desired something from his hand to place beside the two pictures he possessed by Raphael. The authorities of Bologna wanted to him to design a façade for their church of St Petronius; those of Genoa to cast a statue in bronze of their great commander, Andrea Doria. Cardinal Grimani begged hard for any picture or statue he might have to spare; other amateurs importuned him for so much as a pencil drawing or sketch. Lastly his friend and partisan Sebastian del Piombo at Rome, ever eager to keep up the feud between the followers of Raphael and those of Michelangelo, by boiled him in Raphael's death to return at once to Rome, and take out of the hands of the dead master's pupils the work of painting still remaining to be done in the Vatican chambers. Michelangelo complied with none of these requests. All that we certainly know of his doing between 1518 and 1522 is the blocking out in the rough of four more of the "Slaves" for the tomb of Julius, and carrying out a commission, which he had received from three citizens of Rome as early as 1514, for a statue of the risen Christ. The roughed-out "Slaves" now stand immersed in a grotto in the Boboli Gardens, Florence; the Christ, practically finished by the master himself but with the last touches added by pupils, stands in the church, for which it was destined, of Sta Maria sopra Minerva at Rome; there is little in it either of devotional spirit or imaginative power, although, in those parts which Michelangelo himself finished, there is extreme accomplishment of design and workmanship.

The next twelve years of Michelangelo's life (1522-1534) were spent at Florence, and again employed principally in the service of his capricious and uncongenial patrons—the Medici. The plan of a great group of monuments to deceased members of this family had long been agitated in their council, and the finished tomb of Julius II., who had been so lately interred in San Lorenzo, was first broached to Michelangelo in 1520 by Cardinal Giulio de' Medici. No practical impulse, however, was given to the work until Giulio, after the death of Leo X. and the brief pontificate of the puritanical and iconoclastic Adrian VI., had in his turn become pope in 1523 under the title of Clement VII. Even then the impulse was a wakening one. First Clement proposed to associate another artist, Sansovino, with Michelangelo in his task. This proposal being on Michelangelo's peremptory demand abandoned, Clement next distracted the artist with an order for a new architectural design—that, namely, for the proposed Medicean or "Laurentian" library. When at last after many changes of scope and scheme the plans for the sepulchral chapel or "Sagrestia Nuova" took shape, they did not include, as had been at first intended, memorials to the founders of the house's greatness, Cosimo (pater patriae) and Lorenzo the Magnificent, or even to Pope Leo X. himself, but only to two younger members of the house lately deceased, Giuliano, duke of Nemours, and Lorenzo, duke of Urbino. Michelangelo brooded long over various designs for this work, and was still engaged on its execution when his time being partly also taken up by the building-plans for the Medicean library—when political revolutions interposed to divert his industry. In 1527 came to pass the sack of Rome by the Austrians, and the apparently irretrievable ruin of Pope Clement. The Florentines seized the occasion to expel the Medici from their city, and set up a free republican government once more. Naturally no more funds for the works in San Lorenzo were forthcoming, and Michelangelo, on the invitation of the new signory, occupied himself for a while with designs for a group of Hercules and Cacus, and another of Samson
and the Philistines—the latter to be wrought out of a block of marble which had been rough-hewn already for another purpose by Baccio Bandinelli. Soon, however, he was called to Rome by Clement VII, who desired his assistance against his enemy Charles V. Having been reconciled, both alike were now bent on bringing Florence again under the rule of the Medici. In view of the approaching siege, Michelangelo was appointed engineer-in-chief of the fortifications. He spent the early summer of 1530 in strengthening the defences of San Miniato; from July to September he was absent on a diplomatic mission to Ferrara and Venice. Returning in the middle of the latter month, he found the cause of Florence hopeless from internal treachery and from the overwhelming strength of her enemies, and determined to leave the city, and depart again suddenly for Venice. There for a while he remained, negotiating for a future residence in France. Then, while the siege was still in progress, he returned once more to Florence; but in the final death-struggle of her liberties he bore no part.

When in 1530 the city submitted to her conquerors, no mercy was shown to most of those who had taken part in her defence. Michelangelo believed himself in danger with the rest, but on the intervention of Baccio Valori he was presently taken back into favour and employment by Pope Clement. For four years, from 1531 to 1535, he was employed on the completion of the Medici monuments, with the help from 1532 of Giovanni Montorsoli and other pupils, and on the building of the Laurentian library. In 1533 he suffered a severe illness; in 1532 he made a long stay at Rome, and entered upon yet another contract for the completion of the Julian monument, to be reduced now to a still more shrunken scale and to be placed not in St Peter's but in the church of San Pietro in Vincoli. In the autumn of 1534 he left Florence for good. What remained to be done in the Medici chapel was done by pupils, and the chapel was not finally closed before 1545.

The statues of the Medici monument take rank beside the "Moses" and the "Slaves" as the finest work of Michelangelo's central time in sculpture. They consist of a Madonna and Child and of the two famous monumental groups, each composed of an armed and seated portrait-statue in a niche, with two emblematic figures reclining on each side of a sarcophagus below. The "Madonna and Child" (left unfinished because the marble was short in bulk) combines astonishingly the divers qualities of realistic motive and natural animation with learned complexity of design and imposing majesty of effect. It was set up finally—not at all in accordance with the artist's first intention—against a blank wall of the chapel, and flanked at wide intervals by two mosaic reliefs of the workmen who fashioned it. The portraits are treated not realistically but typically. In that of Lorenzo seems to be typified the mood of crafty brooding and concentrated inward thought; in that of Giuliano, the thought of outward action. To this contrast of the meditative and active characters corresponds a contrast in the emblematic groups accompanying the portraits. At the side of the statue of Florence rise the statues of "Apollo" and "Vulcan.

The statues "Moses" and "Vulcan" (now in the Florence Museum), and "Michielangelo's Day" —the former a female, the latter a male, personification; the former sunk in an attitude of deep but uneasy slumber, the latter (whose head and face are merely blocked out of the marble) lifting himself in one of wrathful and disturbed awakening. For Michelangelo's unfinished grandeur of style, and for the sense which his works convey of a compulsive heat and tempest of thought and feeling in the spirit than he thus conceived them, both these attitudes must be charged with an inexpressible grandeur. As grand, but far less violent, are those of the two companion figures that recline between sleep and waking on the sarcophagi of the pensive Lorenzo. Of these, the male figure, at the feet of the statue of Florence, is known in the inscription as "The Mourning of Michelangelo," and artistically as "Day" and "Night." 

In Michelangelo's original idea, partly founded on antique precedent in pedimental and sarcophagus groups, figures of "Earth" and "Heaven" were to be associated with those of "Night" and "Day," as (in the famous "Museo dell' Accademia," Florence) and of "Earth" and "Heaven" with those of "Morning" and "Evening." 

Other works of 1532-1534—"Victory" marble (National Museum, Florence). A youthful conqueror standing over a bearded enemy, whose shoulders he crushes down with his left knee. Fine and typical work; whether one of the group can be identified as the hero of the Julian monument, or having some connexion with the "Hercules and Cacus" and "Samson and the Philistine," subjects sought after for the Signory in 1528, must remain uncertain. For the former of these the deceased patron of the Albert Museum, for the latter a plaster model at the Casa Buonarroti, are claimed, perhaps rightly, as original. "David" (formerly "Apollo"), marble, unfinished (National Museum, Florence). Both the authenticity and the approximate date of this fine work are beyond doubt; of its origin and destination we are uninformed. "Crouching boy" marble, unfinished (the Hermitage, Petersburg), another masterly sketch in marble; the seated boy stoops forward between his parted knees, having both hands occupied with his left foot; the figure blocked out of the marble, with the least possible attention to the marble, as a sketch and motive enigmatical. "Cupid," kneading, apparently in the tempo of the fresco, with a bow, marble (Victoria and Albert Museum). Probably, but not quite certainly, authentic; if so, then of 1530 or thereabouts; its identification with the early Cupid done for Jacopo Galli in Rome in 1496 is untenable. "Leda," painting, done for the duke of Ferrara, but withheld because of the misconduct of his messenger, and given by the master to his pupil Antonio Mini in 1534; lost. A fine injured tempera painting of the subject in the store-rooms of the National Gallery in London may presumably be an early copy.

Michelangelo had fully purposed, as soon as he could get free of his task on the Medici tombs, to devote all his powers to the completion of the Julian monument in accordance with the new contract of 1532. But his intention was again frustrated when Pope Clement insisted that he must complete his decorations of the Sixtine Chapel by painting anew the great east wall above the altar, adorned until then by frescoes of Perugino. The subject chosen was the Last Judgment; and Michelangelo began to prepare sketches. In the autumn of 1534, in his sixtieth year, he settled finally, and for the remainder of his life, at Rome. Immediately afterwards Clement died, and was succeeded by a Farnese under the title of Paul III. Even more than his predecessor, Paul insisted on claiming the main services of Michelangelo, for his own notions; and indeed his intentions drifted. For the first seven years after the artist's return to Rome, his time was principally taken up with the painting of the colossal and multitudinous "Last Judgment." This being completed in 1541, he was next compelled to undertake two more great frescoes—one of the Conversion of Paul and another of the Martyrdom of Peter—in a new chapel which the pope had caused to be built in the Vatican, and named after himself—Capella Paolina.

The frescoes of the Sixtine Chapel are probably the most famous single picture in the world. In it Michelangelo shows more than ever the omnipotence of his artistic science, and the fiery daring of his conceptions. But the work, so far as its deplorably deteriorated condition admits comparison, is hardly comparable in the qualities of colour and decorative effect to the earlier and far more nobly inspired frescoes of the ceiling. It is to these and not to the "Last Judgment" that the student must turn if he would realize what is best and greatest in the art of Michelangelo.

The frescoes of the Pauline Chapel are on their part so injured as to be hardly susceptible of useful study or criticism. In their ruined state they bear evidence of the same tendencies that made the art of Michelangelo in its latest phase so dangerous an example to weaker men—the tendency, that is, to seek for unequalled energy and violence of action, both in place and out, for "terribleness" quod e, and to design actions not by help of direct study from nature, but by scientific deduction from the abstract laws of structure and movement. At best these frescoes can never have been happy examples of Michelangelo's art.

Other Work of the years 1534-1540. SCULPTURE. During the fifteen years when Michelangelo was mainly engaged on these paintings, he had also been enabled to acquire himself, although in a manner that can have been satisfactory to none concerned, of his engagements to the heirs of Julius. Once more the influence of the papacy had to be buoyed up to other engagements to their disadvantage. By a final contract dated 1542, it was agreed that the "Moses" executed thirty years before, seated on a low plinth in a central recess, should be the chief figure of the new
Michelangelo's incompletion, Bologna. In Michelangelo's niche was His position year which, conceiving, Christ occupying friends large those later master's probably the first by, making drawings, or pupils must exist of genious at Florence; there roughed nearly "Phaeton," "Leah," "Surprised," "Sketches," etc. These, meaning an unfinished sketch in marble of a life-size "Pietà" (Palazzo Rondini, Rome)—the mourning mother, standing on an elevation behind her son, holds his body upright in his hands. He had begun after 1550 a complicated and more finished group of the "Pietà," with the corpse of Christ collapsing in utter relaxation through the arms of those who try to uphold it; this Michelangelo destinies for his own sacrifice; it stands now in the cathedral at Florence.

Painting—"The Entombment of Christ" (National Gallery, London). This unfinished painting bears all the marks of Michelangelo's design, and must have been begun from a cartoon by him, probably of about 1555–1560. The touch of his own hand seems evident in some parts, particularly the body of Christ; other parts, in various degrees of incompleteness, are apparently the work of various pupils.

For nearly all his great life-works mentioned above, preparatory sketches and studies by the master's hand exist. These, with a large number of his own drawings, form his own notes and not for any other use, are of infinite value and interest to the student. Michelangelo was the most learned and scientific as well as the most inspired and daring of draughtsmen, and from boyhood to extreme old age never ceased to practice with pen, chalk or pencil. He is said to have burned vast numbers of his drawings with his own hand and caused others to be burned by friends and pupils to whom he had given them, so that the possessor must be less than a fool of what he executed. But there are some 250 genuine sheets—enough to let us follow and understand his modes of conceiving, preparing and maturing his ideas at all stages of his life. These are scattered in various collections, chiefly public; those in England (at the British Museum, the University Galleries, Oxford, and the Royal Library, Windsor), are quite half the whole number; other important examples remain still at what was first the home of his heirs, the Casa Buonarroti at Florence; others at the Uffizi, Florence; the Venice Academy; the Albertina, Vienna; the Louvre; the Conde Museum at Chantilly; the Berlin Museum; and, not least, the Teyler Museum at Haarlem. By means of these drawings and the many published facsimiles we are best able to trace the progress of the master's genius and its secrets. We see him diligently coping in yet another medium, using his sinews and brain, his brain and body in endless schemes of rearrangement, and studies from his own sketches, the "David," the "Bathers Surprised," the accessory figures for the tomb of Julius as first conceived, and the great series of the Sixtine Chapel decorations. But in the working out of the Sixtine Chapel, chiefly the figures of the ceiling, comes into use along with the pen, and many of the finest studies for the "Slaves" or "Atlases" and other decorative figures of the ceiling are in the latter material (many more studies are preserved for these subordinate figures than for the main compositions). After the Sixtine Chapel period the pen gives way to red or black chalk almost entirely. Sketches are rare for the great abortive scheme of the Julius monument; almost non-existent for the equally abortive San Lorenzo façade; fairly abundant for the various stages of the Medici monument scheme in its architectural parts, but not for the great figures. About the time of Michelangelo's final change of design from the St Peter's to Rome (1546), he began his movement of making highly finished and fully shaded drawings of classic or symbolic subjects in red or black chalk for presentation to his friends or pupils. Among those of Tommaso Cavaliere, the subject of his passionate Platonic affection, from about 1532. The figures of Phaeton, the "Titans," the "Pharises," the "Men shooting at a Mark," are well-known examples; in this class of work the Windsor contain the most perfect. At the beginning of the same period were produced drawings little less powerful and finished of Christian subjects, especially the "Crucifixion," "Entombment," "Resurrection," Caravaggio, and the great series of the "Last Judgment," for which there exist both general sketches and a particular study. A few extant drawings for the Cappella Paolina a faltering both of the imagination and of the hand become discernible. To the same or to a similar period belongs some tentative drawings done either directly for, or nearly in the spirit of, the "Crucifixion" which he is recorded to have painted with so much devotion for Vittoria Colonna. About many of these, for all their immensity of feeling, is a wavering touch betraying the approach of infirmity; so there is about many of the architectural studies done for the buildings in Rome of which he charged his last years, the old impressive power and penetration are not wanting in some even of the latest drawings that have come down to us.

During his later years the long-pent human elements of fervour and tenderness in Michelangelo's nature had found vent and utterance such as they had never found before. He had occasionally practised poetry in youth, and there are signs of some transient love-passages during his life at Bologna. But it was not until towards his sixtieth year that the springs of feeling were fairly opened; and, once opened, they were masterful and stormy, life-scorched and labour-hardened.

About 1532–1534 we find him beginning to address impassioned sonnets—of which the sentiment is curiously comparable to that expressed in some of Shakespeare's—to a beautiful and gifted youth, the young Roman noble Tommaso Cavaliere. Soon afterwards he made the acquaintance of the pious, accomplished, and high-souled lady, Vittoria Colonna, widow of the Marquess Pescara. For ten years until her death, which happened in 1547, her friendship was the great solace of Michelangelo's life. On her, in all loyalty and reverence, he poured all the treasures of his mind, his heart, and his power, to the end of tenderness and devotion. She was the chief inspirer of his poetry—of which, along with her praises, the main themes are the Christian religion, the joys of Platonic love, and the power and mysteries of art. Michelangelo's poetical style is strenuous and concentrated like the man. He wrote with labour and much self-correction; we seem to feel him flinging himself on the material of language with the same overwhelming energy and vehemence with which contemporaries describe him as flinging himself on the material of marble—the same impetuosity of temper that continued to life even in his seclusion; but with far less either of innate instinct for the material or of trained mastery over its difficulties.

And so the mighty sculptor, painter, and poet reached old age. An infirmity which settled on him in 1544, and the death of Vittoria Colonna in 1547, left him broken in health and heart. But his strength held on for many a year longer yet. His father and brothers were dead, and his family sentiment concentrated itself on a nephew, Leonardo, to whom he showed unremitting practical kindness, coupled with his usual suspiciousness and futilness of temper. In almost all his relations to the world he continued to try to end and to manifest the same loyal and righteous heart, accompanied by the same masterful, moody, and estranging temper, as in youth. Among the artists of the younger generation he held a position of absolute ascendency and authority; nor was his example, as we have said, by any means altogether salutary for them. To artists, and to a certain number of chosen friends, belonging chiefly to the lettered, diplomatic, and secretarial classes, he was more accessible and affable than he had been to any one in earlier days, though still formidable in moods of scorn and scoffing. His great age and fame had made him the most honoured citizen of Rome, to whom the highest, both of his fellow countrymen and foreigners, were eager to do homage. During the last years of his life he made but few more essays in sculpture, and those not successful, but was much employed in the fourth art in which he excelled—that of architecture. A succession of popes demanded his services for the embellishment of Rome. Between 1536 and 1546 he was engaged on plans for the rearrangement and reconstruction of the great group of buildings on the Capitol—plans which were only partially and imperfectly carried out during his lifetime even after his death. For all his relations to the palace called after the name of the pope's family the Farnese. On the death of Antonio da San Gallo he succeeded to the venerable and coveted office of chief architect of St Peter's church, for which he remodelled all the designs, living to see some of the main features, including the supports and lower portion of the great central dome, carried out in spite of all obstacles, according to his plans. The dome as it stands is his most conspicuous and one of his noblest monuments: the body of the church was completed in a manner quite different from his devising. Other
great architectural tasks on which he was engaged were the reconstruction of the Porta Pia, and the conversion of a portion of the baths of Diocletian into the church of Sta Maria degli Angeli; the great cloister with its hundred columns, now used as the Museo delle Terme, is the only part of this reconstruction which has survived. Michelangelo must indeed have been in charge of these vast schemes and responsibilities, the heroic old man's last remains of strength gave way. He died on the threshold of his ninety-ninth year, on the 18th of February 1564.

AUTHORITIES.—For the earlier bibliography of Michelangelo, which is extensive, see the useful though very imperfect compilation of Passavant, Bibliografia di Michelangelo Buonarroti, &c. (Rome, 1824). The most important of the biographies and the more or less chronological order, are the following: V. Giovio, supplement to the fragmentary Dialogus de viris litteris illustris, written soon after 1527, first published in the second edition of Vite della letteratura italiana (1581); G. Vasari, in Vite degli più eccellenti architetti, pittori, e scultori, &c. (Florence, 1550); A. Condovi, Vita di Michelangelo Buonarroti (1553); this account, for which the author, a pupil and friend of the master's, had long been collecting materials, was much fuller than that of Vasari, who made use of it in rewriting his own life of Michelangelo for his second edition, which appeared after the master's death (1568). The best edition of Vasari is that by Milanesi (Florence 1879-1883); of Condovi, that by Gori and Mariette (Paris, 1746); for English readers there is a useful translation with notes, by Sir Charles Holroyd. The first additions of importance were found in the publications of the Academy of Science in Rome, 1754; 2nd ed. by Ticcozi, Milan, 1822); the next by Cay, Caricaggi e incision (1840). Portions of the correspondence preserved in the Buonarroti archives were published by Guasti in his notes to the Nuovissime lettere di Michelangelo Buonarroti, ed. G. Milanesi (Florence, 1875). This material was first employed in a connected but too trivial narrative by A. Gotti, Vita di Michelangelo (Florence, 1875). Next followed C. Heath Wilson, The Early Life of Michelangelo (Fremantle, 1876), and G. Holroyd, The technical remarks in which, especially as concerns the fresco paintings, are still valuable. Other lives of Michelangelo are by Anton Springer, in his Michelangelo u. Raphael (Leipzig, 1883); J. A. Symonds, The Life of Michelangelo (London, 1893), full of valuable matter on the history and spirit of Michelangelo's times, but not trustworthy in the criticism of his works; H. Mackowsky, Michelangelo (Berlin, 1908), excellent in all respects, and a masterly compass; Emile Gebhardt, Michel-Ange, sculpteur et peintre (1868) is a handsome volume of reproductions with text. Michelangelo, by Fritz Knapp, in the Klassiker der Kunst series (Stuttgart, 1906) is a compendious and exhaustive work. For abbreviated compilations, the standard authority is H. Wöllflin, Die Jugendarbeiten Michelangelos (Munich, 1891, and later editions), a masterly work, though not exhaustive in all respects. J. F. Joffe, in his life of Michelangelo, display of the Sixtine frescoes, magnificently illustrated, is by E. Steinmann, Die Statistische Kapelle, vol. ii. (Munich, 1902). Consult also C. Just, Michelangelo (Leipzig, 1903), and with caution H. Thode, Michelangelo u. das Ende der Renaissance (Berlin, 1902-1903). The poems of Michelangelo of the first sound edition is that already referred to, G. Guasti, Rime di Michelangelo Buonarroti (1863); in earlier editions the text had been recklessly tampered with, and the rugged individuality of the master's style smoothed. The first edition with German translations was published by Hasenclever (Leipzig, 1875); and a thorough critical edition by Karl Frey (Berlin, 1897); for English high school student translations J. G. Symonds, Mich. and the Standard Edition of Michelangelo's Complete Works (London, 1878), invaluable. On the drawings of Michelangelo see especially B. Berenson, The Drawings of Florentine Painters (London, 1903). A critical study of Michelangelo's work the way in which the important examples are reproduced and discussed, unfortunately not arranged chronologically, is Karl Frey, Die Zeichnungen Michelangelos (Berlin, 1908 sec.), still in progress. An elaborate life by the author of Le Vies de France (Michelet, Histoire de la révolution française) is in progress, and his work is also in progress, but is more to be prized for documentary fullness and accuracy than for critical insight.

MICHELET, JULES (1798-1874), French historian, was born at Paris on the 21st of August 1798, of a family which had Huguenot traditions. He was placed by nature a prodigy, very prosperous, and the son at an early age assisted him in the actual work of the press. A place was offered him in the imperial printing office, but his father was able to send him to the famous Collège or Lycée Charlemagne, where he distinguished himself. He passed the university examination in 1821, and was shortly after appointed to a professorship of history in the Collège Rollin. Soon after this, in 1824, he married. The period of the restoration and the July monarchy was one of the most favourable to rising men of letters of a somewhat similar cast of mind that has ever been known in France, and Michelet had powerful patrons in Villermé, Victor Cousin and others. But, though he was an ardent politician (having from his childhood embraced republicanism and a peculiar variety of romantic free-thought), he was first of all a man of letters and an inquirer into the history of the past.

His earlier works were school-books, and they were not written at a very early age. Between 1825 and 1827 he produced divers sketches, chronological tables, &c., of modern history. His Précis of the subject, published in the last-mentioned year, is a sound and careful book, far better than anything that had appeared before it, and written in a sober yet interesting style. In the same year he was appointed maître de conférences at the École normale. Four years later, in 1831, the Introduction à l'histoire universelle showed a very different style, exhibiting no doubt the idiosyncrasy and literary power of the writer to greater advantage, but also displaying the peculiar visionary qualities which made Michelot the most stimulating, but the most untrustworthy (not in facts, which he never consciously falsifies, but in suggestion) of all historians.

The events of 1830 had dismused him, and put him in a better position for study than before; he was admitted to the Record Office, and a deputy-professorship under Guizot in the literary faculty of the university. Very soon afterwards he began his chief and monumental work, the Histoire de France. But he accompanied this with numerous other books, chiefly of erudition, such as the Oeuvres choisies de Vico, the Mémoires de Luther écris par lui-même, the Origines du droit français, and somewhat later the Proces des templiers. 1838 was a year of great importance in Michelot's life. He was in the French ministry, and under his direction the archives, which had fed his natural aversion to the principles of authority and ecclesiasticism, and at a moment when the revived activity of the Jesuits caused some real and more pretended alarm he was appointed to the chair of history at the Collège de France. Assisted by his friend Edgar Quinet, he began a violent polemic against the unpopularity and the principles which it represented, a polemic which made their lectures, and especially Michelot's, one of the most popular resorts of the day. He published, in 1839, his Histoire romaine, but this was in his graver and earlier manner. The results of his lectures appeared in the volumes Le Prêtre, la Faim, la Famille, et le Peuple de Michelot these books show that he was not unskilled in the apocalyptic style which, partly borrowed from Lamennais, characterizes Michelot's later works, but they contain in miniature almost the whole of his curious ethicopolitical creed—a mixture of sentimentalism, communism, and anti-sacerdotalism, supported by the most eccentric arguments, but urged with a great deal of eloquence. The principles of the outbreak of 1848 were in the air, and Michelot was not the least important of those who condensed and propagated them; indeed his original lectures were of so incendiary a nature that the government were inclined to suppress them. The actual revolution broke out Michelot, unlike many other men of letters, did not attempt to enter on active political life, and merely devoted himself more strenuously to his literary work. Besides continuing the great history, he undertook and carried out, during the years between the downfall of Louis Philippe and the final establishment of Napoleon III., an enthusiastic Histoire de la révolution française. Despite or because of its enthusiasm, this was by no means Michelot's best book. The events were too near and too well known, and hardly admitted the picturesque sallies into the blue distance which make the charm and the danger of his earlier works. In actual picturesque ness as well as in general veracity of picture, the book cannot approach Carlyle's; while as a mere chronicle of the events it is inferior to half a dozen prosaic histories older and younger than itself.
The coup d'état lost Michelet his place in the Record Office, as, though not in any way identified with the republic administratively, he refused to take the oaths to the empire. But the new régime only kindled afresh his republican zeal, and his second marriage (with Mlle Adèle Malaret, a lady of some literary capacity, and of republican belongings) seems to have further stimulated his powers. While the history steadily held its way, a crowd of extraordinary little books accompanied and diversified it. Sometimes they were expanded versions of its episodes, sometimes what may be called commentaries or companion volumes. In some of the best of them natural science, a new subject with Michelet, to which his wife is believed to have introduced him, supplies the text. The first of these (by no means the best) was Les Femmes de la révolution (1854), in which Michelet's natural and inimitable faculty of dithyrambic too often gives way to tedious and not very conclusive argument and preaching. In the next, L'Outeau (1856), a new and most successful vein was struck. The subject of natural history was treated, not from the point of view of mere science, nor from that of sentiment, nor of anecdote nor of gossip, but from that of the abbat who prevent democratic pantheism, and the result, though, as was to be expected, unequal, was often excellent. L'Insecte, in the same key, but duller, followed. It was succeeded by L'Amour (1859), one of the author's most popular books, and not unworthy of its popularity, but perhaps hardly his best. These remarkable works, half pamphlets half moral treatises, succeeded each other as a rule at the twelve months' interval, and the succession was almost unbroken for five or six years. L'Amour was followed by La Femme (1860), a book on which a whole critique of French literature and French character might be founded. Then came La Mer (1861), a return to the natural history class, which, considering the powers of the writer and the attraction of the subject, is perhaps a little disappointing. The next year (1862) the most striking of all Michelet's minor works, La Sorcière, made its appearance. Developed out of an episode of the history, it has all its author's peculiarities in the strongest degree. It is a nightmare and nothing more, but a nightmare of the most extraordinary verisimilitude and poetic power.

This remarkable series, every volume of which was a work at once of imagination and of research, was not even yet finished, but the latter volumes exhibit a certain falling off. The ambitious Bible de l'humanité (1864), an historical sketch of religions, has but little merit. In La Montagne (1868), the last of the natural history series, the tricks of staccato style are pushed even farther than by Victor Hugo in his less inspired moments, though—as is inevitable, in the hands of such a master of language and style—the effect is frequently grandiose if not grand. Nos fils (1860), the last of the string of smaller books published during the author's life, is a tractate on education, written with ample knowledge of the facts and with all Michelet's usual sweep and range of view, if with visibly declining powers of expression. But in a book published posthumously, Le Banquet, these powers reappear at their fullest. The picture of the industrious and famishing populations of the Riviera is (whether true to fact or not) one of the best things that Michelet has done.

To complete the list of his miscellaneous works, two collections of essays, written and partly published at different times, may be mentioned. These are Les Soldats de la révolution and Légendes démocratiques du nord.

The publication of this series of books, and the completion of his history, occupied Michelet during both decades of the empire. He lived partly in France, partly in Italy, and was accustomed to spend the winter on the Riviera, chiefly at Hyères. At last, in 1867, the great work of his life was finished. In the usual edition it fills nineteen volumes. The first of these deals with the history up to the death of Charlemagne, the second with the flourishing time of feudal France, the third with the 13th century, the fourth, fifth, and sixth, with the Hundred Years' War, the seventh and eighth with the establishment of the rural power under Charles VII. and Louis XI. The 16th and 17th centuries have four volumes apiece, much of which is very distantly connected with French history proper, especially in the two volumes entitled Renaissance and Réforme. The last three volumes carry on the history of the 18th century to the outbreak of the Revolution. Michelet was perhaps the first historian to devote himself to anything like a picturesque history of the middle ages, and his account is still the most vivid that exists. His inquiry into manuscript and printed authorities was most laborious, but his lively imagination, and his strong religious and political prejudices, made him regard all things from a singularly personal and interested point of view. The strain on his health increased, and for further convenient texts for his polemic, are handled at inordinate length, while others are readily dismissed or passed over altogether.

Uncompromisingly hostile as Michelet was to the empire, its downfall and the accompanying disasters of the country once more stimulated him to activity. Not only did he write letters and pamphlets during the struggle, but when it was over he set himself to complete the vast task which his two great histories had almost covered by a Histoire du XIXe siècle. He did not, however, live to see Waterloo, and the best criticism of it is perhaps contained in the opening words of the introduction to the last volume—"l'âge me presse." The new republic was not altogether a restoration for Michelet, and his professorship at the Collège de France, of which he contended that he had never been properly deprived, was not given back to him. He died at Hyères on the 6th of February 1874. Almost all Michelet's works, the exceptions being his translations, compilations, &c., are published in uniform size and in about fifty volumes, partly by Marpon and Flammarion, partly by Calmann Lévy. He has not received much recent attention from critics and monographers, but his Oeuvres du droit français, recherchées dans les symboles et formules du droit universel was edited by Émile Faguet in 1890 and went into a second edition in 1900. See G. Monod, Jules Michelet; Études sur la vie et ses œuvres (Paris, 1905).

MICHELET, K. L.—MICHELL (G. Sa.)

MICHELET, KARL LUDWIG (1801-1893), German philosopher, was born on the 4th of December 1801, at Berlin, where he died on the 16th of December 1893. He studied at the gymnasium and at the university of his native town, took his degree as doctor of philosophy in 1824, and became professor in 1829, a post which he retained till his death. Educated in the doctrine of Hegel, he remained faithful to his early teaching and spent his life in defending and continuing the Hegelian method. His first notable work was the System der philosophischen Moral (Berlin, 1848), an extension of the Hegelian theory of responsibility. In 1836 he published, in Paris, a treatise on the Metaphysics of Aristotle, written in French and crowned by the Académie des Sciences Morales et Politiques. He wrote also two other treatises on Aristotle, Nikomachische Ethik (2nd ed., 1848) and Die Ethik des Aristoteles in ihrem Verhältnis zum System der Moral (1857). His own views are best expressed in his Vorlesungen über die Persönlichkeit Gottes (1841) and Die Epiphänien der ewigen Persönlichkeit des Gottes. This philosophical theology developed in these works has been described as a "Neo-Chrétien Nationalism."

Among his other publications may be mentioned Geschichte der letzten Systeme der Philosophie, in Deutschland von Kant bis Hegel (1837-1838); Anthropologie und Psychologie (1840); Essai de logique (Paris, 1845); Naturrecht und Rechtsphilosophie (1866); Hegel der unwiederlegte Weltpolitiker (1870). Wahrheit aus meinem Leben (1886). From 1832 to 1842, Michelet was engaged in publishing the complete works of Hegel, and in 1845 he founded the Berlin Philosophical Society which continuously represented the Hegelianism of Germany. He was the first editor of Der Gedanke (1860), the official organ of the society.

MICHELL, JOHN (1724-1793), English natural philosopher and geologist, was born in 1724, and educated at Queens' College, Cambridge. His name appears fourth in the Tripos list for 1748-1749; and in 1755 he was moderator in that examination which became M.A. in 1752, and B.D. in 1761. He was a fellow of his college and a university lecturer, and also professor of geology in 1762, and in 1797 rector of Thornhill in Yorkshire, where he died on the 20th of April 1793. He was
elected a fellow of the Royal Society in the same year as Henry Cavendish (1760). In 1750 he published at Cambridge a work of some eighty pages entitled A Treatise of Artificial Magnets, in which is shown an easy and expeditious method of making them superior to the best natural ones. Besides the description of the method of magnetization which still bears his name, this work contains a variety of accurate magnetic observations, and is distinguished by a lucid exposition of the nature of magnetic induction. He was the original inventor of the torsion balance, which afterwards became so famous in the hands of its second inventor Coulomb. Micheli described it in his proposal of a method for obtaining the mean density of the earth. He did not live to put his method into practice; but this was done by Henry Cavendish, who made, by means of Michelli's apparatus, the celebrated determination that now goes by the name of Cavendish's experiment (Phil. Trans., 1768). His most important geological essay was entitled Conjectures concerning the Cause and Observations upon the Phenomena of Earthquakes (Phil. Trans., 1766), which showed a remarkable knowledge of the strata in various parts of England and abroad.

Michelli's other contributions to science are: "Observations on the Comet of January 1760 at Cambridge, Phil. Trans. (1760); "A Recommendation of Hadley's Quadrant for Surveying," ibid. (1765); "Proposal of a Method for measuring Degrees of Longitude upon the Sea," ibid. (1761); "An Inquiry concerning the Probable Parallax and Magnitude of the Fixed Stars," ibid. (1767); "On the Twinkling of the Fixed Stars," ibid. (1767); "On the Movement of Discovering the Distance, Magnitude, &c., of the Fixed Stars," ibid. (1754).

MICHEL OF NORTHGATE, DAN (fl. 1340). English writer, the author of the Avey bile of Inwyt. Nothing is known of him except what can be gathered from his work. It is a literal translation in the Kentish dialect of a French treatise entitled Le Somme des vices et des vertus (also known as Le Miroir du monde or Le Livre des commandemens, &c.), which was written in 1279 by Laurentius Gallus, a Dominican monk and confessor to Philip III. of France. This work was translated into Flemish, Catalonian, Spanish and Italian, and appears in no less than six English translations. Dan Michel's autograph MS. is preserved in Arundel MS. 57, which states that the work was completed in the year 1340 on the eve of the apostles Simon and Jude by Dan Michel of Northgate, a brother of the cloister of St Austin of Canterbury. The value of the book is chiefly philological as an authenticated and dated example of the southern dialect.

The Avey bile of Inwyt was edited for the Roxburgh Club by the Rev Joseph Stevenson in 1835, and for the Early English Text Soc. by Richard Morris in 1876.

MICHELOZZO DI BARTOLOMMEO (1391-1472?), Italian sculptor, was a Florentine by birth, the son of a tailor, and in early life a pupil of Donatello. He worked in marble, bronze and silver. The statue of the young St John over the door of the Duomo at Florence, opposite the Baptistery, is by him; and he also made the beautiful silver statuette of the Baptist on the altar-frontal of San Giovanni. Michelozzo's great friend and patron was Cosimo de Medici, whom he accompanied to Venice in 1433 during his short exile. While at Venice, Michelozzo built the library of San Giorgio Maggiore, and designed other buildings there. In 1426, together with Donatello, he erected an open-air pulpit at an angle of the cathedral of St Stephen at Prague. The magnificent Palazzo del Comune of Florence was designed by him; it is one of the noblest specimens of Italian 15th-century architecture, in which the great taste and skill of the architect has combined the delicate lightness of the earlier Italian Gothic with the massive staleness of the classical style. With great engineering skill Michelozzo shored up, and partly rebuilt, the Palazzo Vecchio, then in a ruinous condition, and added to it many important rooms and staircases. When, in 1437, through Cosimo's liberality, the monastery of San Marco at Florence was handed over to the Dominicans of Fiesole, Michelozzo was employed to rebuild the domestic part and remodel the church. For Cosimo I. he designed numerous other buildings, mostly of great beauty and importance. Among these were a guest-house at Jerusalem for the use of Florentine pilgrims, Cosimo's summer villa at Careggi, and the strongly fortified palace of Cafaggiolo in Mugello. For Giovanni dei Medici, Cosimo's son, he built a very large and magnificent palace at Fiesole. In spite of Vasari's statement that he died at the age of sixty-eight, he appears to have lived till 1472. He is buried in the monastery of San Marco, Florence. Though skilled as a sculptor and engineer, his fame rests chiefly upon his architectural works, which claim for him a position of very high honour even among the greatest names of the great 15th-century Florentines.

See Hans Stegmann, Michelozzo di Bartolommeo, eine kunstgeschichtliche Studie (1888); Fritz Wolff, Michelozzo di Bartolommeo (1906); cf. also Hans Semper, Donatello (1887).

MICHIGAN, a north central state of the United States, situated between latitudes 41° 44' and 47° 30' N. and longitudes 82° 25' and 90° 31' W., and consisting of two peninsulas—the upper or northern and the lower or southern—separated by a strait. The upper or northern peninsula is bounded N. by Lake Superior; E. by lakes Superior, George, Huron, and Michigan, and by St Mary's River, which separates it from the Province of Ontario, Canada; S. by lakes Huron and Michigan and the Straits of Mackinac, which separate it from the lower peninsula; and S. and W. by Wisconsin, and the Menominee, Montreal and Brulé Rivers, which separate it in part from Wisconsin. The lower southern peninsula is bounded N. by lakes Michigan and Huron and the Straits of Mackinac, E. by lakes Huron and St Clair Rivers, and S. by St Clair, Detroit Rivers, which separate it from Ontario; S. by Ohio and Indiana, and W. by Lake Michigan. In size Michigan ranks eighteenth among the states of the Union, its total area being 57,680 sq. m., of which 500 sq. m. are water surface.

Physical Features.—Physiographically the history of the state is similar to that of Minnesota. The northern part is rugged moun-
taneous old kind, not completely worn down by erosion; and the southern part is a portion of the old coastal plain, whose layers contain salt, gypsum and some inferior coal. Lake Huron on the east and Lake Michigan on the west of the lower peninsula are each 815 ft. above sea-level, and Lake Superior on the north of the upper peninsula is 602 ft. above sea-level. For the most part the surface of the state is gently undulating and at a slight elevation above the lakes. The low marshy slopes of the lakes; a part of the lower peninsula is occupied by a plateau of considerable dimensions, and the north-west part of the upper peninsula is rugged with hills and small mountains. Lake Michigan, Saginaw Bay west by south through the valleys of the Saginaw, Maple and Grand rivers, is a depression—the former channel of an old glacial river—which in elevations for a considerable area are less than fifty feet; above this the surface rises gradually to the south-east of this depression a water-parting with summits varying from about 400 to 600 ft. above the lakes extends from a point between Saginaw Bay and Lake Huron south by west to the south border of the state and beyond. The east slope descends quite rapidly to a low flat belt from 5 to 40 m. wide along the east border of the state south from Lake Huron. From Lake Huron to the south-east shore of Saginaw Bay a wide sandy beach is followed northward by precipitous shores abounding in rocks and bluffs. West of the divide and south of the depression, south-west Michigan is occupied by the valleys of the St Joseph, Kalamazoo and Grand rivers, by the gently rolling uplands that form the north and south borders of the state; and the north-eastern part of this state has a level surface of much varying elevation; which here and there rise to a height of from 100 to 200 ft. or more along the shore of Lake Michigan, and are formed on this side (but not on the Wisconsin side) of the lake by the over-lying formation of the Michigan sea. The northern and north-western portions of the lower peninsula— including the counties of Rosecommon and Missaukee, parts of Wexford and Oscawau, and those to the north and north-west, and the Lake Huron Lakes— are occupied by the Lake Huron lakes. The land slopes gently down to the depression and the lower shores of Lake Michigan and Saginaw Bay. This forms the upper

---

1 This is the northernmost point of the mainland; the northerly part of the islands north-east of Isle Royal and belonging to Wisconsin is more than 30 m. farther north.

2 In addition, within the boundaries of Michigan, are approximately 16,653 sq. m. of Lake Superior, 12,992 sq. m. of Lake Michigan, 6925 sq. m. of Lake Huron and 460 sq. m. of lakes St Clair and Erie.

A
of the lower peninsula.
peninsula is more irregular than that
west and south
portion extending through the middle from east to
from west of the centre to Green Bay, is either flat and even swampy
or only gently undulating. Eastward from Green Bay are two ranges
of hills: the one lining the south shore and ranging from 100 to
300 ft. in height, the other close to or touching the north shore and
reaching in places an elevation of 600 ft. above Lake Superior.
The famous Pictured Rocks in Alger county on the lake shore, east
of Munisirig, form the west portion of this north range; they are of
sandstone formation, extend for several miles along the coast, rise
almost perpendicularly from the water's edge, and display an
interesting diversity of shapes as well as a great variety of tints and

hues, especially of gray, blue, green and yellow. The most rugged
portion of the state is farther west. South and south-east of Keweenaw Bay, in the Marquette iron district, is an irregular area of
mountains, hills, swamps and lakes, some of the mountain peaks
of the Huron Mountains (in Marquette county) rising to an elevation
of 1400 ft. or more above the lake. These and a peak in the Porcupine

Mountains (2023 ft. above the sea) in the north-west part of Ontonagon county are the highest in the state. To the south of this is

marked somewhat regularly by east
a general north-east and south-west
through Keweenaw peninsula to the Wisconsin border and

the Menominee
and west ridges.

iron district,

Extending

in

beyond is the middle of three approximately parallel ranges, separated from each other by flat lands, with here and there an isolated
peak (in the Porcupine Mountains) having an elevation of from 900 to
1400 ft. above the lake. The north portion of these ranges, together
with Isle Royale some distance farther north, which is itself traversed
by several less elevated parallel ridges, contains the Michigan copperbearing rocks; while to the south, along the Wisconsin border, is
another iron district, the Gogebic. The rivers of the entire state
In the interior
consist of numerous small streams of clear water.
of the upper peninsula, along the east border of the lower peninsula
south from Lake Huron, and in Saginaw valley, they are rather
sluggish; but many of the larger streams of the lower peninsula
have sufficient fall to furnish a large amount of water-power, while
the small streams that flow into Lake Superior from the central
portion of the upper peninsula as well as some of the larger ones
farther west, have several falls and rapids; in places also they are
lined with steep, high banks. Most of the larger rivers of the state
the Muskegon, Grand, St Joseph, Manistee and Kalamazoo are in
the west portion of the lower peninsula. Several thousand lakes of
clear water, formed by glacial action, dot the surface of the state, and
many of them are lined with picturesque woodland shores. Islands
in lakes Superior, Michigan and Huron are scarcely less numerous.
Fauna and Flora. Michigan, especially the north portion, still

in game.
The mammals include black bear, deer, lynx,
porcupine, fox, squirrels, hares, rabbits, musk rats, minks, weasels,
skunks and woodchucks. Among the game birds are quails (" Bob
White"), "partridges" (ruffed grouse), ducks, geese, woodcocks,
Of song birds the favourites are the robin,
snipes and plovers.
thrushes, bobolink, oriole, chickadee, meadow-lark, cat-bird, bluebird, wrens and warblers.
Among fishes, white fish, lake trout,
perch, herring, sun-fish, bass, sturgeon, pickerel, suckers, German
carp and fresh-water drum abound in the lakes. The speckled
trout thrives in many of the streams.
Before it was settled by the whites the area now included in Michigan was a forest, except in the south-west, where there were a few
small prairies, possibly cleared by the Indians. The remainder of the
south part of this area for about 60 m. along the southern boundary
was a part of the great hardwood forest of the Ohio Basin with
woods varying with soil and drainage: on the drier gravel lands
were oak forests consisting of red, black and white oak, hickory,
ash, cherry, basswood and walnut in depressions there were maple,
elm, ash, beech, sycamore, poplar and willow; and in the southeast there were a few chestnuts and tulip trees.
North of this
southern hardwood forest there were pine forests on the sandier
land, mixed hardwoods and conifers on the loam and clay, and
tamaracks and cedar in the swamps. The sandy lands were in
part burnt over by Indians, and there was a growth of scrub oak,
aspens and huckleberry bushes. The tamarack and cedar swamps

abounds

;

now have a growth,
on their edges, of spruce, balsam,
especially
white pine, soft maple, ash and aspens. In 1909 about 25

farmland, and about 40
Red
oak, birch, elm, ash, white cedar, hemlock, basswood, spruce,
poplar, balsam, fir and several other kinds of trees are found in many
sections; but a large portion of the merchantable timber, especially
in the lower peninsula, has been cut. 1
Among forest shrubs are the
willow, hazel, alder, shrub maple, birch, hawthorn, dogwood,
elderberry, viburnum and snowberry.
Yews are common in the
north, and dwarf juniper in the south. In 1900 the woodland area,
including stump lands, was estimated at 38,000 sq. in., or nearly
two-thirds of the entire state. Huckleberry,
blackberry and raspberry bushes are common in the north sections.
Smilax, clematis,
honeysuckle and woodbine are the commoner forest vines.

west portion of that peninsula that the

greatest, both the summer and winter isotherms being
there deflected more than half the length of the peninsula. On the
other hand, the prevailing winds of the upper peninsula being north-

moderation

is

westerly, the lakes have little effect on the temperature there; and
so, while in the south-west the extremes are not great, in the rest
of the state they have ranged within two years from 104
F. at
points in the south-east to 49 F. in the north-west. Throughout
the state July is invariably the warmest month, February the coldest,
the mean annual temperature is about 45 F. The mean annual
precipitation is not far from 31 in., a little more than one-half of
which falls during the five growing months from May to October;
the rain is evenly distributed over all parts of the state, but the snow

exceptionally heavy along the north shore of the upper peninsula.

horses 704,000.
Michigan produces the bulk of the peppermint crop of the United
States, and it is in the front rank as a fruit-producing state.
Barley and buckwheat are grown chiefly in the east part of the
lower peninsula south of Saginaw Bay. Potatoes are grown in considerable quantities in the north-west part of the lower peninsula in
the vicinity of Grand Traverse Bay as well as throughout the southern
portion of the state the largest crops of beans are grown in the south
central part of the lower,peninsula, and of peas in the counties
bordering on Lake Huron. Kalamazoo, Jackson, Washtenaw,
Lenawee, Ingham, Bay and Muskegon are the leading celery-producing counties; the peppermint district is in the south-west corner of
the state; and market gardening is an important industry both in the
south-west and in the south-east counties. All the principal fruits
are grown in largest quantities in what is commonly known as the
fruit belt in the south-west, particularly in Berrien, the corner county.
The fresh-water fish caught in the Great Lakes by residents in
Michigan exceed in value those caught by residents of other states,
and in 1907 the catch was valued at $1,806,767. Nearly one-half
30th in quantity and value arc taken from Lake Michigan, and,

Minerals. Of the mineral products (for which the state is noted)
ron is the most valuable.
This mineral was discovered in the
Vlarquette district along the shore of Lake Superior early in the
1 8th
century, but active operations for mining it did not begin until
1845; in 1877 mining of the same mineral began farther south in
:he Menominee district, and seven years later farther west along
the Wisconsin border in Gogebic county.
The annual product
steadily increased from 3000 long tons in 1854 to 1 1,830,342 in 1907
rom 1890 to 1901 Michigan ranked first in the union as an ironjroducing state, but after 1901 its product was exceeded by that
of Minnesota. Up to 1909 it was estimated that 380,417,085 tons
of ore were shipped from the Lake Superior region.
Next in value
among the mineral products is copper; there are about twenty copper
nines in Keweenaw peninsula and its vicinity. The Calumet and
rlecla mine, in the central part of that peninsula, is probably the
most profitable copper mine in the world; up to 1909 it had paid
;


about $107,850,000 in dividends. Copper mining in the state began about the same time as iron mining, and the quantity mined increased from 12 long tons in 1845 to 102,543 in 1906. In 1893, 39,175 long tons were mined. The principal product of any other state; from 1847 to 1883 its copper product was more than one-half of all the states, but after 1887 (except in 1891) Michigan was the leader in Michigan in 1906 and in 1907 the yield in both Arizona and Montana was greater than in Michigan. Fields of bituminous coal extend over an area of about 10,000 sq. m. in the central portion of the lower peninsula; but 82% of the production is in Houghton and Jackson counties. In 1835 and there was a slow increase in the output until 1882 (135,339 short tons); then there was a tendency to decrease until 1897, from which time the product increased from 273,502 short tons in 1897 to 726,007 short tons in 1907. The principal mines are in Saginaw, Bay, Eaton, Jackson, Huron and Shiawassee counties. Salt wells are numerous in the middle and south-east sections of the state, and the market for the production increased to 2398; but the great period of railway building in Michigan, from late enough in 1830, but little progress had been made in 1837 when the state began the construction of three railways and two canals across the peninsula and the western end of Lake Michigan. The Michigan Central was completed from Detroit to Ypsilanti in 1847, and the Michigan Southern was in operation in November 1840, and considerable work was done on the proposed Michigan Northern and Southern railroads. The government was not competent to carry on the work and sold its interests to private companies. In 1850 there were 342 m. completed, and from then until 1855 the mileage increased to 3208; but the period of railway building in Michigan, from late 1830 to 1890, when the mileage was increased to 7108. By the close of 1898 it had further increased to 8629.35. The principal lines are the Michigan Central, the Port Marquette, the Lake Shore & Michigan Southern, the Grand Rapids & Indiana, the Ann Arbor, the Grand Trunk, the Chicago & North-Western, the Duluth South Shore & Atlantic, the Minneapolis, St Paul & Sault Ste. Marie, and the Chicago, Milwaukee & St Paul. The road of railway commissioners, which in 1897 succeeded a commissioner (whose office was created in 1873) learns complaints, has power to suspend the orders of the majority in minor importance to railway companies, and reports annually to the legislature. The general property is empowered to appoint a commission to fix transportation rates for railways and express companies. Besides railway communications, Michigan has a coast line of about 1500 m., along which vessels of 2000 tons can sail and find several good harbours, the water communication having been extended and improved by several canal systems. The state undertook to construct the canal at the Sault Ste. Marie, which passes the rapids of St Mary's River; the St Clair Flats, at the north end of Lake St Clair, by which a deeper channel is made through shallow water; and the Portage Lake, in the copper district, which connects the upper lake with Lake Superior. The state undertook to construct that at Sault Ste. Marie, in 1857 but little had been accomplished in 1852 when the national government granted 750,000 acres of land to the state in aid of the enterprise, and three years later, when the railroad was completed, the national government has enlarged its locks so as to make it navigable for vessels drawing 21 ft. of water. The national government contributed the canal at the St Clair Flats in 1871 and contributed land for aid in the construction of that connecting lake. Portage and Superior, which was completed in 1873 and passed under national control in 1891.

Population.—The population of Michigan in 1880 was 1,830,937; in 1890 it was 2,093,889, an increase of 27.9% within the decade; in 1900 it was 2,420,836, a further increase of 16.4% within the decade. In 1830 the state had a population of about 541,653 in 1840, 1,28,675 in 1850, 2,093,889 in 1860. That of the total population, in 1850, 2,308,563 or 99.07% were whites, 15,861 were negroes, 6,554 were Indians, 240 were Chinese, and 9 were Japanese. 1,879,349 or 77.6% were native born and 541,005 were foreign-born, 184,398 of the foreign-born being natives of Canada (1,591,155 English; 3,248 French), 125,074 of Germany, 43,839 of England, and 30,406 of Holland. In 1890 952,479 emigrants had moved to emigrants of different nationalities were reported: of these 432,193 were Roman Catholics, 128,675 Methodists, 105,803 Lutherans, 45,876 Baptists, 37,560 Presbyterians, 28,345 Methodists, 26,345 of the Protestant Episcopal Church. In 1900 39.3% of the total population lived in houses having at least 2500 inhabitants.

Administration.—The constitution under which Michigan is now governed was first adopted in 1830, when it was felt that the powers which the first one, that of 1835, conferred upon the executive and the legislature were too unrestricted. In 1916 it was revised, and many changes were made.

The constitution admits of amendment by an affirmative vote of three-fifths of both houses of the legislature. An amendment may be proposed by a petition signed by more than 20% of the total number of electors who voted for secretary of state at the preceding election, and such an amendment (unless approved by a majority vote in a joint meeting of the two houses of the legislature) is submitted to popular
vote at the next election and comes into effect only if it receives a favourable majority of the popular vote. Amendments suggested by the legislature have been frequently adopted, and one, adopted in 1862, provided that the question of a general revision shall be submitted to the popular vote once every sixteen years and at such other times as may be provided by law. When this question was submitted for the first time, in 1866, the vote was to revise the constitution or to adopt a convention; but the purpose was rejected at the polls. The revision by the Constitution Convention of 1907-1908 was adopted by popular vote in 1908.

In its present form the constitution confers suffrage upon every male citizen of the United States who is twenty-one years of age and who has resided in the state six months and in his township or ward twenty days immediately preceding an election; and any woman may vote in an election involving the direct expenditure of public money or the issue of bonds if she have property assessed for taxes in any part of the district or territory affected by the election in question. At the head of the executive department is the governor, who is elected for two years, and who at the time of his election must be at least thirty years of age and must have been a citizen of the state for at least one year immediately preceding his election and for the two years immediately preceding a resident of the state. A lieutenant-governor, for whom the same qualifications are prescribed, is elected at the same time for the same term. Under the first constitution the secretary of state, treasurer, auditor-general, attorney-general, commissioner of the land office, superintendent of public instruction and the judges were all appointed by the governor, but under the present one they are elected and only minor officers are appointed. In 1863 the legislature created a board of four members to be appointed by the governor, one of whom must be a physician, another an attorney, and made it its duty to investigate the case of every convict for whom a petition for pardon is received and then report and recommend to the governor what it deem expedient. The governor's salary is fixed by the revised constitution of 1908 at $5000 a year. The lieutenant-governor succeeds the governor in case of vacancy, and next in order of succession comes the secretary of state.

The legislature, consisting of a Senate of 32 members, and a House of Representatives of 100 members (according to the constitution not less than 64 and not more than 100), meets biennially, in odd-numbered years, at Lansing. Both senators and representatives are elected for a term of two years by single districts, except that a township or city which is entitled by its population to more than one representative elects its representatives on a general ticket. Beginning in 1913 and at each subsequent tenth year, the legislature, under the revised constitution of 1908, rearranges the senatorial districts and reapportions the representatives among the counties and districts, using as a basis the returns of the two preceding decennial census; the taking of a state census between the decennial periods is discontinued.

No bill can pass either house except by an affirmative vote of a majority of the members elected to that house, and on its third reading the ayes and nays must be taken and recorded; for appro- priation bills a two-thirds majority of all members elected to each house is required. All legislation must be by bill, legislation by joint and concurrent resolutions thus being prevented. No bill may be passed at a regular session until it has been printed and in posses- sion of each house for five days; no bill may be passed at a special session on any subject not expressly stated in the governor's proclamation or submitted by special message. The governor has ten days (Sundays not being counted) in which to exercise his veto power (which may be applied to any item or items of any bill making appropriations of money and embracing distinct items), and an affirmative vote in both house of two-thirds of the members elected is required to pass a bill over his veto. Under the revised constitu- tion of 1908 any bill passed by the legislature and approved by the governor, except appropriation bills, may be referred by the legis- lature to the judicial electors; and if, by a vote of two-thirds of the law unless approved by a majority of the electors voting thereon; no local or special act, passed by the legislature, takes effect until it is approved by a majority vote of the electors in the affected district.

The administration of justice is entrusted to a supreme court, a continually increasing number of circuit courts (thirty-eight in 1909), one probate court in each county, and not exceeding four justices of the peace in each township. The supreme court is composed of one chief justice and seven associate justices, all elected for a term of ten years, not more than two retiring every two years; it holds four sessions annually, exercises a general control over the inferior courts, may issue, hear and determine any of the more important writs, and has appel- late jurisdiction only in all other important cases. There is only one circuit court judge for a circuit, unless the legislature provides more; none is elected for more than six years. The circuit court judges have original jurisdiction in all matters civil and criminal, hear appeals from the lower courts, and must hold at least four sessions annually in each county of the circuit. Each county elects a judge of probate for a term of four years; he has original concurrent jurisdiction with the circuit court in matters of probate, and has original jurisdiction in all cases of juvenile delinquents and dependents. The legislature may provide for the election of more than one judge of probate in a county with more than 100,000 inhabitants. Justices of the peace are elected by the townships for a term of four years, not more than four in each township, in civil matters they have exclusive jurisdiction of cases in which the demand does not exceed $500 and concurrent jurisdic- tion with the circuit courts in contract cases in which the demand does not exceed $300.

For purposes of local government the state is divided into eighty-three counties, each of which is in turn divided regularly by N. and S. and E. and W. lines into several townships. In the more sparsely inhabited counties of the upper peninsula and in the N.E. section of the lower peninsula the townships are much larger than in other parts of the state. The officers of the township are a supervisor, clerk, treasurer, highwaycommissioner, one overseer of highways for each highway district, a justice of the peace, and not more than four constables, all of whom are elected at the annual township meeting in April. The supervisor, two of the justices of the peace and the clerk constitute the township board, whose duty it is to settle claims against the township, audit accounts, and publish annually an itemized statement of receipts and disbursements. The supervisor is also the township assessor, and the several township supervisors constitute the county board of supervisors who equalize property valuations as between townships, authorize townships to borrow money with which to build or repair bridges, are entrusted with the care and management of the property and business of the county, and may borrow or raise by tax what is necessary to meet the more common expenses of the county. Other county officers are a treasurer, clerk, sheriff, register of deeds, attorney, surveyor and two coroners, each elected for a term of two years, a school commissioner elected for a term of four years, and one or more notaries public appointed by the governor.

Under the revised constitution of 1908 the former classifica- tion of cities into four classes and the practice of granting special charters were abolished, and the legislature is required to provide by general laws for the incorporation of cities and villages; "such general laws shall limit their rate of taxation for municipal purposes and restrict their powers of borrowing money and contracting debts." Cities and villages are permitted—upon authorization by the affirmative vote of three-fifths of the electors voting on the question—to own and operate electric light, heat, water, and light to an amount not more than one-fourth that furnished by them in each case within their corporate limits; but no city or village of less than 25,000 inhabitants may own or operate transportation facilities. Under the revision of 1908 corporate franchises cannot be granted for a longer term than thirty years.

Law.—A wife in Michigan has the same right to her property acquired either before or after marriage as she would have if single, except that she cannot under ordinary circumstances give, grant or
sell it to another without her husband's consent. Grounds for a divorce are adultery, physical incapacity at the time of marriage, separation for three years or more, desertion for two years, habitual drunkenness, extreme cruelty, or in case of refusal of the husband to provide for her maintenance when sufficiently able to do so; but in the cases where the parties were married outside of Michigan, theactus reus must rest in the husband, if both parties are residents of the state at least one year before petitioning for the same. An insolvent debtor's homestead—consisting of not more than 40 acres of land with a house thereon, or a house and lot in a city or village not exceeding $1500 in value; and not more than $3000 of household property—is exempt from execution. For several years previous to 1876 a clause of the constitution prohibited the sale of intoxicating liquors for human consumption; but this liquor business has been subjected to a heavy tax, and since 1887 the prohibition of liquor traffic has been left to the option of each of the several counties. A state court of mediation and arbitration, consisting of three members appointed by the governor, to be of the age of 35 years, was created in 1889 to inquire into the cause of grievances threatening or resulting in any strike or lock-out and to endeavour to effect a settlement.

Charitable and Penal Institutions. — The state supports the Michigan Asylum for the Insane (opened 1859), at Kalamazoo; the Eastern Michigan Asylum for the Insane (opened 1878), at Pontiac; the Northern Michigan Asylum for the Insane (opened 1886), at Traverse City; the Michigan Asylum for the Dangerous and Criminal Insane (established 1885), at Ionia; the Upper Peninsula Hospital for the Insane, at Newberry; a Psychopathic Hospital (established 1907), at Allegan; the State Hospital for the Consumptive (established 1885), at Jackson; the Michigan Reformatory (established 1887), at Ionia; the State Hospital of the Deaf (established 1885), at Marquette; the Industrial School for Boys, at Lansing; the Industrial School for Girls (established 1879), near Adrian; the State Public School (opened 1874), at Coldwater, a temporary home for dependent children; the Michigan Soldiers' Home (established 1885), at Flint; and the School for the Blind, at Lansing; an Employment Institution for the Blind (established 1903), at Saginaw; the Home for the Feeble Minded and Epileptic (established 1893), at Lapeer; and the Michigan Soldiers' Home (established 1885), at Grand Rapids. Each of these institutions is under the control of a board of three or more members appointed by the governor, with the approval of the Senate, and the head of the department is the State Board of Corrections and Charities, consisting of the governor and four other members appointed by him with the approval of the Senate, for a term of eight years, one retiring every two years. This board is required to visit each of the institutions at least once a year to ascertain its condition and needs, and all proposed appropriations for their support, plans of buildings, proposed systems of sewerage, ventilation and heating must be submitted to it.

Education.—Michigan was a pioneer state in creating the American educational system; she began the organization of it at the time of her admission into the Union in 1837, and has since been noted for the high standard of her schools. Each township operating under the District Act has two school inspectors—one being elected at each town meeting for a term of two years—who with the township clerk constitute the township board of education, to be the inspectors, and to this board is given authority to divide the territories among the several school districts and to exercise a general supervision over the several schools within their jurisdiction; a township may be organized as a single district, called a “township unit district.” The qualified electors of each district having an ungraded school elect a moderator, a director and a treasurer—one at each annual school meeting—for a term of three years, who constitute the district school board, and this board is entrusted with ample power for directing the affairs of the school. In a district having more than 100 children of school age a graded school under the control of five trustees is formed whenever two-thirds of the electors vote for it at a town meeting, and the trustees of a graded school may establish a high school whenever a majority of the electors authorize them to do so. A high school may also be established in any township in which there is no incorporated village or city if when the question is submitted to the electors of that township a majority of the votes cast are in the affirmative. Each county has a county school commissioner, elected for a term of four years, who exercises a general supervision over the schools within his jurisdiction, and a board of examiners, consisting of three members (including the commissioner) and appointed by the several boards of county supervisors, from whom teachers receive certificates. Finally, at the head of all the public elementary and secondary schools of the state is the state superintendent of public instruction, elected for a term of two years; he is ex officio a member and secretary of the state board of education, and a member, with the right to speak but not to vote, of all other boards having control of public instruction in any state institution. In every district having as many as 800 children between the ages of five and twenty the state requires that the school be taught not less than nine months a year; and a compulsory education law requires the attendance of all children between the ages of eight and fifteen for four months each year, between the same ages for the full school year, and between the ages of ten and fifteen only if found frequenting public places without lawful occupation.

The higher state institutions of learning consist of a university, to which graduates of high schools on an accredited list are admitted without examination, four normal schools, an agricultural college, and a school of mines. The university (at Ann Arbor) was established in 1837, and is under the control of a board of regents elected by the people for a term of eight years, two every two years; the president of the institution and the superintendent of public instruction are members of the board but without the right to vote. The state normal schools are: the Michigan State Normal College at Ypsilanti (organized in 1849); the Central Michigan Normal School at Mount Pleasant (established in 1867); the Northern State Normal College at Marquette (established in 1867); the Western State Normal School at Kalamazoo (established in 1894). All of them are under the state board of education, which consists of the state superintendent of public instruction and seven other members, one every two years, for a term of six years. The agricultural college at East Lansing, 3 m. east of Lansing, is the oldest in the United States; it was provided for by the state constitution of 1850, organized in 1855 and opened in 1857, and is under the control of the state board of agriculture, consisting of the president of the college and six other members elected by popular vote for a term of six years, two every two years. In 1890 it had 35 instructors, 253 students, and a library collection of 12,000 volumes. Other prominent institutions of the state but not maintained by it are: Albion College (Methodist Episcopal; opened in 1833), at Albion; Hillsdale College (Free Baptist; established 1837, at Hillsdale; Kalamazoo College (Baptist, 1855), at Kalamazoo; Adrian College (controlled by the Methodist Protestant Church since 1867), at Adrian; Olivet College (Congregational, 1859), at Olivet; Hope College (Reformed, 1866), at Holland; Detroit College (Roman Catholic, 1879), at Detroit; Alma College (Presbyterian; incorporated 1886), at Alma; and some professional schools at Detroit (q.v.).

Finance. The revenue of the state is derived almost wholly from property, about 87%, from a direct or general property tax; the rest from various specific or indirect taxes, such as the liquor tax and the inheritance tax. The direct tax, other than that on the corporation income of the railroad corporations or the state, is assessed by the county assessors, or in cities and incorporated villages by the officers named in the county for that service, on what is supposed to be the full cash value of the property. The assessment roll thus prepared is reviewed by a local board of review; an equalization committee is appointed for the state but not maintained by it: Albion College (Methodist Episcopal; opened in 1833), at Albion; Hillsdale College (Free Baptist; established 1837, at Hillsdale; Kalamazoo College (Baptist, 1855), at Kalamazoo; Adrian College (controlled by the Methodist Protestant Church since 1867), at Adrian; Olivet College (Congregational, 1859), at Olivet; Hope College (Reformed, 1866), at Holland; Detroit College (Roman Catholic, 1879), at Detroit; Alma College (Presbyterian; incorporated 1886), at Alma; and some professional schools at Detroit (q.v.).
the last decade of the century. The present constitution (as revised in 1908) forbids the contraction of a state debt exceeding $250,000 except for repelling an invasion. In 1815 it was determined that the power of the minor civil divisions is restricted by a general law.

The early experience of the state with banks was scarcely less sanguine than with public improvements. Although there were already thirteen banks in the state in 1817 yet the cry against monopoly was loud, and so in that year a general banking law was passed whereby ten or more freeholders, by written instrument, could create a bank with capital of less than fifty thousand nor more than three hundred thousand dollars and begin business as soon as 30% of the capital was paid in in specie. Only a few provisions were made, and those ineffective, the law prohibiting the issue of notes; later in the same legislature passed an act for the suspension of specie payments until the 6th of May 1838, and the consequence was that the state was flooded with irredeemable paper currency. But most of the "wild" banks had gone out of existence by 1839, and in 1844 the bank act of 1837 was declared unconstitutional. Profiting by this experience, the framers of the constitution of 1850 inserted a provision in that document whereby no general banking law can have effect until it has been submitted to the people and has been approved by a majority of the votes cast on the question. This provision is included in the revised constitution adopted in 1890, with an additional provision that no amendment shall be made to any banking law unless it shall receive an affirmative two-thirds vote of both branches of the legislature. The present banking law provides that the number of state banks and branches shall not be less than one for each county of not more than 1500 inhabitants, nor less than $25,000 in a city of not more than 5000, nor less than $50,000 in a city of between 5000 and 20,000, nor less than $100,000 in a city of between 20,000 and 50,000, nor less than $250,000 in a city of over 50,000; all larger than $250,000 shall be supported by a stock and all state banks and savings banks are required to keep on hand at least 15% of their total deposits. Every stockholder in a bank is made individually responsible for the amount of bank stock at the par value, in addition to the said stock. And all banks are subject to the inspection and supervision of the commissioner of the state banking department, who is appointed by the governor with the approval of the Senate for a term of four years.

History.—From 1613 until 1760 the territory now within the borders of Michigan formed a part of New France, and the first Europeans to found missions and settlements within those borders were Frenchmen. Two Jesuits, Raymbault and Jogues, visited the site of Sault Sainte Marie as early as 1641 for the conversion of the Chipewas; in 1668 Marquette founded there the first permanent settlement within the state; three years later he had founded a mission among the Hurons at Michilimackinac; La Salle built a fort at the mouth of the Saint Joseph in 1679; and in 1701 Cadillac founded Detroit as an important point for the French control of the fur trade. But the missionaries were not interested in the settlement of the country by Europeans, the fur traders were generally opposed to it, there was bitter strife between the missionaries and Cadillac, and the French system of absolutism in government and monopoly in trade were further obstacles to progress. Even Detroit was so expensive to the government of the mother country that it was occasionally talked of abandoning; and so during the last fifty-nine years that Michigan was a part of New France there were no new settlements, and little if any growth in those already established. During the last war between the English and the French in America the Michigan settlements passed into the possession of the English, Detroit in 1760 and the others in 1761, but the time had not yet come for much improvement. The white inhabitants, still mostly French, were subjected to an English rule that until the Quebec Act of 1774 was chiefly military, and as a consequence many of the most attractive tracts of land lay untouched. and had most of whom had been allies of the French, were so ill-treated, both by the officers and traders, that under Pontiac, chief of the Ottawas, a simultaneous attack on the English posts was planned. Detroit was besieged for five months and both Michilimackinac and Saint Joseph were taken. Moreover, the English policy, which first of all was concerned with the profits of trade and manufacture, gave little more encouragement to the settlement of this section of the country than did the French. By the Treaty of Paris, in 1783, which concluded the American War of Independence, England is now Michigan passed to the United States, and in 1787 this region became a part of the North-West Territory; but it was not until 1796 that Detroit and Mackinac (Michilimackinac), in accordance with Jay's Treaty of 1794, were surrendered to Great Britain. In 1800, on the division of the North-West Territory, the west portion of Michigan became a part of the newly-established Indiana Territory, into which the entire area of the present state was embraced in 1822, when Ohio was admitted as a state. Then, finally, in 1825, Michigan Territory was organized, its south boundary being then described as a line drawn from the same starting point through the middle of Lake Michigan until it intersected Lake Erie, and its west boundary a line drawn from the same starting point through the middle of Lake Michigan to its north extremity and then due north to the north boundary of the United States. In 1812, during the second war between Great Britain and the United States, General William Hull, first governor of the Territory, although not greatly outnumbered, surrendered Detroit to the British without a struggle; in the same year also Mackinac was taken, and Michigan again passed under British rule. This state of short duration, however, for so soon after Commodore Oliver H. Perry's victory on Lake Erie, in September of the next year, Detroit and the rest of Michigan except Mackinac, which was not recaptured until July 1815, were again taken into the possession of the United States. Up to this time the Territory had still remained for the most part a wilderness in which the fur trade reaped the largest profits, its few small settlements being confined to the borders; and the inaccurate reports of the surveyors sent out by the national government described the territory in a way that some of its more sanguine proprietors believed to be as well suited for agriculture as it was for animal husbandry. The larger number of hostile Indians was also a factor in making the Territory unattractive. But during the efficient administration of Lewis Cass, governor of the Territory from 1813 to 1831, the interference of the British was checked and many of the Indians were removed to the west of the Mississippi; printing presses, established during the same period at Detroit, Ann Arbor, Monroe and Pontiac, became largely instrumental in making the country better known; the first steamboat, the "Walk-in-the-Water," appeared at Detroit in 1818; the Erie canal was opened in 1825; by 1830 a railway was running between Detroit and Buffalo, and the population of Michigan, which was only 478,000 in 1810 and 889,000 in 1830, increased to 31,639 in 1830 and 212,267 in 1840. In 1839 the Territory had been empowered to send a delegate to Congress. By 1832 the question of admission into the Union had arisen, and in 1835 a convention was called in Detroit, a constitution was framed in May, that constitution was adopted by popular vote in October, state officers were elected, and application for admission was made; but a dispute with Ohio over the boundary between the two caused a delay in the admission by Congress until early in the year 1836. There had been, with internal improvements, the North-West Territory fixed the boundary line as claimed by Michigan, yet that line was found to be farther south than was at the time expected and when the constitution of Ohio was adopted it was accompanied with a proviso designed to secure to that state a north boundary that was north of the mouth of the Maumee River. The territory between the two proposed lines was unquestionably of greater economic importance to Ohio than to Michigan, and, besides, at this particular time there were forcible political reasons for not offending the older state. The consequence was that after the bloodless war between the two states for the possession of Toledo, Congress settled the dispute in Ohio's favor and gave to Michigan the territory since known as the upper peninsula. The boundaries as fixed by Congress were rejected by a convention which met on the 4th of September at Ann Arbor, but they were accepted by the convention of the Jackson party, which met, also at Ann Arbor, on the 6th of December; the action of this latter convention was considered authoritative by Congress, which admitted Michigan into the Union as a state on the 26th of January 1837. Since admission into the Union the more interesting experiences of the Territory wadeamp with others, and the state, which together resulted in serious financial distress; in the utilization of its natural resources, which have been a vast source of
wealth; and in the development of its educational system, in which the state has exerted a large influence throughout the Union. From the beginning of its government under its first state constitution in 1835 until 1855 Michigan had a Democratic administration. With the exception of the years 1840-1843, when opposition to the financial measures of the Democrats placed the Whigs in power. But it was in Michigan that the Republican party received its first official recognition, at a state convention held at Jackson on the 6th of July 1857, and from the beginning of the following year the administration has been Republican with the exception of two terms from 1883 to 1885, and from 1891 to 1893, when it was again Democratic.

GOVERNORS OF MICHIGAN

Territorial.

William Hull

1805-1813

Lewis Cass

1813-1831

Stevens Thompson Mason (acting)

1831

George Bryan Porter

1911

AUTHORITIES.—The Publications of the Michigan Geological Survey (Detroit, Cass & Co., New York, 1858 seq.) deal largely with the mining districts of the upper peninsula. Alexander Winchell, Michigan: Being Condensed Popular Sketches of the Topography, Climate and Geology of the State (1873), is in large measure based upon the Beauties of the Land, W. J. Beal and C. F. Wheeler, Michigan Flora (Lansing, 1892), contains the results of an extensive study of the subject. See also the Twelfth Census of the United States (Washington, 1890-1900); Nicholas Condit, Michigan: A State Cyclopedia (Lansing, 1883); Sectional County Maps (Detroit, 1901); Bela Hubbard, Memoirs of a Half-Century (New York, 1887), a well written account of observations, chiefly upon scenery, fauna, flora and climate; Webster Cook, Michigan: Its History and Government (New York, 1905), written primarily for use in schools and containing a reference bibliography; A. C. McLaughlin, History of Higher Education in Michigan, in Circulations of Information of the United States Bureau of Education (Washington, 1891), being an account of the origin of the public school system and an individual account of each higher institution of learning; T. M. Cooley, Michigan: A History of Government (New York, 1859), a critical but popular narrative by a jurist; J. V. Campbell, Outlines of the Political History of Michigan (Detroit, 1876), also by a jurist of the state; Henry M. Utley and Byron M. Cutchon, Michigan as a Province, Territory and State (14 vols., Detroit, 1896); Michigan Pioneer and Historical Society, Historical Collections: Collections and Researches (Lansing, 1877 seq.); and Publications of the Michigan Political Science Association (Ann Arbor, 1893).

MICHIGAN, LAKE, the only one of the great lakes of North America wholly within the boundaries of the United States, and the second largest body of fresh water in the world. It lies S. of Lake Superior and W. of Lake Huron, between 41° 37' and 46° 55' N. and 84° 45' and 88° W.; is bounded on the N. and E. by the state of Michigan, on the W. by Wisconsin, while Illinois and Indiana touch its S. end. It is 320 m. long, and has an average width of 65 m. The maximum depth recorded by the United States Lake Survey is 870 ft.; the mean level of the surface is 581 ft. above mean sea-level, being the same as that of Lake Huron and 21 ft. below that of Lake Superior. Its area is 22,400 sq. m., and it has a basin of 85,800 sq. m. in area.

The shores of Lake Michigan are generally low and sandy, and the land slopes gradually to the water. The northern shore of the lake is irregular and more rugged and picturesque than the other shores, the summit of the highest peak being about 1,400 ft. above the sea. On the eastern side are numerous sand hills, formed by the wind into innumerable fantastic shapes, sometimes covered with stunted trees and scantly vegetation, but usually bare and rising to heights of from 150 to 250 ft. The south-western shore is generally low, with sand hills system, with shrivelled pines and bur oaks. Along the western shore woods and prairies alternate, interspersed with a few high peaks. The cliffs on the east shore of Green Bay form a bold escarpment, and from this ridge the land slopes gradually to the lake. With the exception of Green and Traverse bays, Lake Michigan has few indentations of the coast line, and except at the north end it is free from islands. The waters near shore are shoal, and as there are few harbours of refuge of easy access navigation is dangerous in heavy storms. Around the lake the climate is equable, for, though the winter weather is severe, and the summer hot, the waters of the lake modify the extremes, the mean temperature varying from 40° to 54° F. The average annual rainfall is 33 in. The finest agricultural land in the United States is near the lake, and there is an immense trade in all grains, fruits, livestock and lumber, and in products such as flour, pork, hides, leather goods, furniture, &c. Rich lead and copper mines abound, as also salt, iron and coal. Abundant water power promotes manufactures of all kinds. Beer and distilled liquors are largely manufactured, and fine building stone is obtained from numerous quarries.

The lake is practically tideless, though true tidal pulsations amounting to 1 in. have been observed in Chicago. In the water of the lake there is a general set of current towards the outlet at the strait of Mackinac, following the east shore, with slight circular currents in the main portion of the lake and at the northern end around Beaver island. These currents vary in speed from 4 to 10 m. per day. Surface currents are set up by prevailing winds, which also seriously affect water levels, lowering the water at Chicago and raising it at the strait, or the reverse, so as greatly to inconvenience navigation. The level of the lake is subject to seasonal fluctuations, reaching a maximum in midsummer and a minimum in February, as well as to alternating cycles of years of high and low water. Standard high-water of 1858 was 3·36 ft. above mean level and standard low-water of 1895, 2·82 ft. below that datum, giving an extreme recorded range slightly over 6 ft.

The northern portion of the lake only is covered with ice in winter, and ice never reaches as far south as Milwaukee. Milwaukee River remains closed on an average for one hundred days—from the beginning of December to the middle of March. The average date of the opening and closing of navigation at the strait of Mackinac, where the ice remains longest, is the 17th of April and the 9th of January respectively. Lines of steamers specially equipped to meet winter conditions, most of them being car ferries, cross the lake and the strait of Mackinac all winter between the various ports.

No notable rivers flow into Lake Michigan, the largest being the Big Manistee and Muskegon on the east shore, and on the west shore the Manistee and the Fox, both of which empty into Green Bay, the most important arm of the lake. The numerous harbours are chiefly artificial, usually located at the mouths of streams, the improvements consisting of two parallel piers extending into the lake and protecting a dredged channel. Sand bars keep filling up the mouths of these channels, necessitating frequent dredging and extension of the breakwaters, work undertaken by the Federal government, which also maintains a network of aids to navigation, including lighthouses and lightships, fog alarms, gas and other buoys, life-saving, storm signal and weather report stations.

MICHIGAN, UNIVERSITY OF—MICHIGAN CITY

Chicago, the principal port on the lake, is at its south-west extremity, and is remarkable for the volume of its trade, the number of vessels arriving and departing exceeding that of any port in the United States and containing more than the half of the commerce of the lake. It is a large railway centre, and the number and size of the grain elevators are noticeable. The port is protected by breakwaters enclosing the lake to a level of the city above the lake being only 14 ft., much difficulty arose in draining it. A sanitary and ship canal 34 m. long was therefore completed in 1900 to divert the Chicago river, a small stream that flows into the lake, to the Des Plaines river, and in 1884 the river Joliet was diverted into the Mississippi at St Louis. The discharge of water is by law so regulated that the maximum flow shall not exceed 250,000 cb. ft. per minute. The city is divided by the channel of the lake, which is enclose by 250,000 ft. of breakwaters. The proceeds of the lake being water of through this artificial outlet is receiving much attention. Milwaukee, situated on the shore of Lake Huron, is the largest harbour of refuge. Escanaba, on Little Bay de Noc (Noquette), in the northern part of the lake, is a natural harbour and a large iron shipping port. Green Bay and Lake Michigan are connected by a canal extending from the lake to the head of Sturgeon Bay. Lake Michigan is connected at its north-east extremity with Lake Huron by the strait of Mackinac, 45 m. long, with a minimum width of 6 m.; the water is generally deep and the shoals lying near the usually travelled routes are well marked.

MICHIGAN, UNIVERSITY OF, one of the principal educational institutions of the United States, situated at Ann Arbor, Michigan. It embraces a department of literature, science and the arts (including industry and commerce), opened in 1841, and including a graduate school, organized in 1892; a department of medicine and surgery, opened in 1852; a department of law, opened in 1859; a school of pharmacy, opened as a separate department in 1876; a homoeopathic medical college, opened in 1875; a college of dental surgery, opened in 1875; and a department of engineering, separately organized in 1893, which includes courses in marine engineering, architecture, and architectural engineering. The university was one of the first to admit women, having opened its doors to them in 1870 as a natural consequence of its receiving aid from the state (since 1867), and since 1900 they have constituted nearly one-half of the student body in the department of literature, science and the arts. In 1907-1908 there were in all departments 350 instructors and 5031 students (1756 in the department of literature, science and the arts; 1355 in the department of engineering; 991 in the department of medicine and surgery; 151 in the department of law; 821 in the school of pharmacy; 82 in the homoeopathic medical college; 268 in the college of dental surgery; and 170 in the summer sessions). Besides the several main department buildings there is a library building, a museum building, several laboratories, a gymnasium for men, and a gymnasium for women. The general library in 1908 contained 172,940 volumes, 3800 pamphlets, and 3370 maps, and the several department libraries brought the total up to 222,000 volumes and 5000 pamphlets. The general museum contains natural history collections, geological and anthropological collections, including the exhibit of the Chinese government at the New Orleans Exposition, which was purchased by the government to the university in 1885; there are besides several special collections in some of the laboratories. The astronomical observatory is surrounded by a movable dome in which is mounted a refracting telescope having a thirteen-inch object glass. The several laboratories are equipped for use in instruction in physics, chemistry, mineralogy, geology, zoology, botany, forestry, actuarial work, engineering, histology, physiology, hygiene, electrotherapeutics, pathology, anatomy and dentistry.

The university is governed from without by a board of eight regents elected by popular suffrage, two biennially, at the same time as the election of judges of the supreme court; from within the government is to a large extent in the hands of a university senate, in which the faculty of each department is represented. The university is maintained by a permanent annuity of $50,000, derived from the land set apart for it by the Ordinance of 1787, by the proceeds of a three-eighths mill tax, and by small fees paid by the students. Its organic relation to the other public schools of the state was well established in 1870, when it was provided that graduates from such high schools as had been examined and approved by a committee of the university should be admitted without examination; one of the most important functions of the university is to prepare students for teaching in the high schools.

The first charter for a university within a state that was now the state was granted by the governor and judges of the Territory of Michigan in 1817, for a "Catholopistemad," or University of Michiganana, with a remarkable "Greek" system of nomenclature for its courses and faculties; this institution did practically nothing teaching. A university was granted in 1821, for a University of Michigan in Detroit; but that was accomplished without the admission of Michigan into the Union as a state in 1837, when by the third charter the aim was to model the institution after the German university minus the theological department, and the university was entrusted to a board of regents and a chancellor appointed by the governor. Branches to correspond to the German gymnasium were established in the principal towns before any money was spent on the University proper, but the question of the constitutionality of their establishment and maintenance arose, and they were soon discontinued. The State of Michigan opened a college in 1837. The first class graduated in 1845. The department of literature, science and the arts was at first much like a New England college. For some time the prospects did not seem promising; but in 1851 a new state constitution provided that the regents should be elected, and directed them to choose a president; and it was under the administration (1852-1865) of the first incumbent of that office, Henry Philip Tappan (1805-1881), that the present broad and liberal basis was established. Although he was a Presbyterian clergyman, he endeavoured at the outset to substitute the tests of scholarship for those of religion; at the same time a scientific curriculum was introduced, courses in pedagogy followed, and in 1878 the elective system, which has since rapidly expanded, was established. President Tappan was succeeded in 1863 by Erastus Otis Haven (1820-1881), who resigned in 1866, and was succeeded temporarily (1869-1871) by Professor Henry S. Frieze (1817-1889), and in 1871 by James Burrill Angell (b. 1839), who resigned in 1900. In 1874-1872 the German seminar method was introduced in graduate work in history, by Prof. Charles Kendall Adams (1835-1902), afterwards president of Cornell University (1885-1892) and of the University of Wisconsin (1892-1902).

See B. A. Hinsdale and L. N. Denmon, History of the University of Michigan (Ann Arbor, 1906); Elizabeth M. Farrand, History of the University of Michigan (Ann Arbor, 1885); and The Quarterly Centennial of the Presidency of James Burrill Angell (Ann Arbor, 1899).

MICHIGAN CITY, a city of Laporte county, Indiana, U.S.A., on the S.E. shore of Lake Michigan, about 40 m. E. by S. of Chicago. Pop. (1890) 10,776; (1900), 14,850, of whom 3602 were foreign-born; (1910 census) 19,027. Michigan City is served by the Chicago, Indianapolis & Louisville, the Lake Erie & Western, the Michigan Central and the Pere Marquette railways, by interurban electric lines, and by several lines of lake steamships. The city contains a United States Life Saving Station and the Indiana State Prison, and is the seat of a Protestant Episcopal bishop. Its transportation

President Angell graduated in 1849 at Brown University, where he was assistant librarian in 1850, and later professor of modern languages in 1853-1860; was editor of the Providence Journal in 1860-1866; was president of the University of Vermont in 1866-1871, was United States minister to China in 1880-1881, was a member of the joint commission of 1887-1888 to settle boundary disputes between the United States and Great Britain, was chairman of the international deep waterways commission in 1896, and in 1897-1898 was United States minister to Turkey.
advantages it make one of the principal commercial cities in the state. Its shipments of lumber are of special importance, and it has also a large transshipment trade in salt and iron ore. The total factory product in 1905 was valued at $63,144,226.

The municipality owns and operates its water-works system. Michmash, a place in Benjamin, about 9 Roman miles north of Jerusalem (Onom., ed. Leg., p. 280), the scene of one of the most striking episodes in Old Testament history (1 Sam. xiv.). Though it did not rank as a city (not being mentioned in Joshua xviii. 21 seq.), Michmash was colonized after the exile (Neh. xi. 31), and, favoured by the possession of excellent wheat-land (Mishna, Men. viii. 1), was still a very large village (Max. t. 3) in the time of Eusebius. The modern Mukhmas is quite a small place.

The historical interest of Michmash is connected with the strategic importance of the position, commanding the north side of the Pass of Michmash, which made it the headquarters of the Philistines and the centre of their forays in their attempt to quell the first rising under Saul, as it was also at a later date the headquarters of Jonathan the Hasmonaean (1 Macc. ix. 73). From Jerusalem to Mount Ephraim there are two main routes. The present caravan road keeps the high ground to the west near the watershed, and avoids the Pass of Michmash, which is another important position. The importance of the latter in antiquity may be judged from Isa. x. 28 seq., led southwards from Ai over an unchallenging plateau to Michmash. Thus far the road is easy, but at Michmash it descends into a very steep and rocky gorge, the sides of which are almost perpendicular. At the bottom of the valley is the Pass of Michmash, a noble gorge with precipitous craggy sides. On the north the crag is crowned by a sort of plateau sloping backwards into a round-topped hill. This little plateau, about a mile east of the present village of Mukhmas, seems to have been the post of the Philistines, lying close to the centre of the insurrection, yet possessing unusually good communication with their establishments on Mount Ephraim by way of Ai and Bethel, and at the same time commanding the routes leading down to the Jordan from Ai and from Michmash itself.

See further C. R. Conder, Tentwork ii. 112 seq., and T. K. Cheyne in Encyc. Brit. 9th ed. i. 250 seq. (R. A. S. M.)

MICHOACÁN, or MICHOACÁN DE OCAMPO, a state of Mexico touching on the Pacific, bounded N. by Jalisco and Guanajuato, E. by Mexico and Guerrero, S. by Guerrero and the Pacific, and W. by the Pacific, Colima, and Jalisco. Pop. (1900), 935,808, chiefly Indians and mestizos. Area, 22,874 sq. m. Its territory is divided into two nearly equal parts by the eastern branch of the Sierra Madre Occidental, the northern part belonging to the great central plateau region, and the southern to an extremely broken region formed by the diverging branches of the Sierra Madre, with their wooded terraces and slopes and highly fertile valleys. The general slope of the southern part is toward the Pacific, and its western limits are marked by the boundary-line with Guerrero. The narrow coastal zone on the Pacific is only 101 m. long and has no ports or towns of importance, the slopes of the Sierra Madre del Pacífico being precipitous and heavily wooded and the coastland sandy, hot and malarial. The Lerma, on the northern frontier, and the Balsas on the southern, are the only rivers of importance of the state, their tributaries within its boundaries being small and swift-flowing. There are several large and beautiful lakes in the state, the best known of which are Patzcuaro and Cuitzeo. Lake Chapala lies on the northern boundary. Michoacán lies within the most active volcanic region of Mexico; Jorullo (4,562 ft.) is near its southern line, and Colima (1,250 ft.) is north-west of it in the state of Jalisco. Earthquake shocks are numerous, and Colima was in violent eruption in 1908-1909.

The highest summit in the state is Tancitaro (12,660 ft.). The climate is for the most part temperate and healthy, but it is hot and unhealthy on the coast. Michoacán is essentially a mining region, producing gold, silver, lead and cinnabar, and having rich deposits of copper, coal, petroleum and sulphur. The natural products include fine cabinet and construction woods, rubber, fruit, palm oil and fibres. The soil of the valleys is highly fertile, and produces cereals in the heights.

regions, and sugar-cane, tobacco, coffee and tropical fruits in the lower. Though the plateau region was settled soon after the arrival of the Spaniards in Mexico, there are large districts on the southern and Pacific slopes that still belong almost exclusively to the Indians. Besides Morelia, the capital and largest city, the principal towns of the state are: La Piedad (pop. 1917, 21,751), an important commercial town on the Lerma river; Tepic, on the Mexican railroad between the Mexican Federal; Zamora (10,372), 75 m. N.W.W. of Morelia; Vitor (8,087), on the Mexican National, 55 m. S.W. of Morelia in a mountainous district celebrated for the fine quality of its coffee; Purundio (7,782), a commercial and manufacturing town 40 m. N.W. of Morelia; Patzcuaro (7,621), on Patzcuaro lake, with a station on the Mexican National, 7535 ft. above sea level; Sahuayo (7,408), 103 m. W. by N. of Morelia near Lake Chapala; Zitacuaro (6,952), 60 m. S.E. of Morelia on a branch of the Mexican National, which also passes through the mining town of Anguango (912) in the same district; and Tzitlamaro (5,970), 46 m. S.S.W. of Morelia in a fertile valley of the Rio de las Balsas basin.

MICKIEWICZ, ADAM (1798-1855), Polish poet, was born in 1798, near Nowogrodeck, in the present Russian government of Minsk, where his father, who belonged to the scholastic or lesser nobility, had a small property. The poet was educated at the university of Vilna; but, becoming involved in some political troubles there, he was forced to terminate his studies abruptly, and was ordered to live for a time in Russia. He had already published a small volume of miscellaneous poetry in Vilna, which had been favourably received by his fellow Slavonic public, and on his arrival at St Petersburg he found himself admitted to the leading literary circles, where he was a great favourite both from his agreeable manners and his extraordinary talent of improvisation. In 1825 he visited the Crimea, which inspired a collection of sonnets in which we may admire both the elegance of the rhythm and the rich Oriental colouring. The most beautiful are The Storm, Bahchiseras, and Exile of the Country Poetess.

In 1828 appeared his Konrad Wallenrod, a narrative poem describing the battles of knights of the Teutonic order with the heathen Lithuanians. Here, under a thin veil, Mickiewicz represented the sanguinary passages of arms and burning hatred which had characterized the long feuds of the Russians and Poles. The objects of the poem, although evident to many, escaped the Russian censors, and it was suffered to appear, although the very motto, taken from Machiavelli, was significant: "Dovete adunque sapere come sono due generazioni da combattere...bisogna essere volpe e leone." This is a reference to a poem and two beautiful lyrics. After a five years' exile in Russia the poet obtained permission to return. He had secretly made up his mind never to return to that country or Poland so long as it remained under the government of the Muscovites. Wending his way to Weimar, he there made the acquaintance of Goethe, who received him cordially, and, pursuing his journey through Germany, he entered Italy by the Splügen, visited Milan, Venice, and Florence, and finally took up his abode at Rome. There he wrote the third part of his poem Deszy, the subject of which is the religious commemoration of their ancestors practised among Slavonic nations, and Pac Wodziéz, his longest poem, by many considered his masterpiece. A graphic picture is drawn of Lithuania on the eve of Napoleon's expedition to Russia in 1812. In this village idyll, as Brückner calls it, Mickiewicz gives us a picture of the homes of the Polish magnates, with their somewhat boisterous but very genuine hospitality. We see them before us, just as the knell of their nationalisation, as the poet says, seems to be sounding, and therefore there is something melancholy and dirige-like in the poem in spite of the pretty love story which forms the main incident. Mickiewicz turned to Lithuania with the loving eyes of an exile, and gives us some of the most delightful pages of Lithuanian races and Lithuanian forests. He describes the weird sounds to be heard in the primeval woods in a country where the trees were sacred. The cloud-pictures
are equally striking. There is nothing finer in Shelley or Wordsworth.

In 1832 Mickiewicz left Rome for Paris, where his life was for some time spent in poverty and unhappiness. He married a Polish lady, Selina Seymann-Veszel, who became insane. In 1840 he was appointed to the newly founded chair of Slavonic language and literature in the Collège de France, a post which he was especially qualified to fill, as he was now the chief representative of Slavonic literature, Pushkin having died in 1837. He was, however, only destined to hold it for a little more than three years, his last lecture having been given on the 28th of May 1844. His mind had become more and more disordered under the influence of religious mysticism. He had fallen under the influence of a strange fanatic named Towkow. His lectures became a medley of religion and politics, and thus brought him under the censure of the Government. A selection of them has been published in four volumes. They contain some good sound criticism, but the philological part is very defective, for Mickiewicz was no scholar, and he is obviously only well acquainted with two of the literatures, viz. Polish and Russian, the latter only till the year 1830. A very sad picture of his declining days is given in the memoirs of Herzen. At a comparatively early period the unfortunate poet exhibited all the signs of premature old age; poverty, despair and his frightful affliction had wrought on their worst effects. In 1840 he founded a weekly newspaper, La Tribu de peuples, but it only existed a year. The restoration of the French Empire seemed to kindle his hopes afresh; his last composition is said to have been a Latin ode in honour of Napoleon III.

On the outbreak of the Crimean War he was sent to Constantinople to assist in raising a regiment of Poles to take service against the Russians. He died suddenly in 1855, and his body was removed to France and buried at Montmorency. In 1900 his remains were disinterred and buried in the cathedral of Cracow, the Saxon Croce of Poland, where rest, besides many of the kings, the greatest of her worthies.

Mickiewicz is held to have been the greatest Slavonic poet, with the exception of Pushkin. Unfortunately in other parts of Europe he is but little known; he writes in a very difficult language, and one which is not the fashion to learn. There were both pathos and irony in the expression used by a Polish lady to a foreigner, "Nous avons votre Mickiewicz à nous." He is one of the best products of the so-called romantic school. The Poles had long groaned under the yoke of the czars, and the country was full of legends and picturesque stories which only awaited the coming poet to put them into shape. Hence the great popularity among his countrymen of his ballads, each of them being connected with some national tradition. Besides Konrad Wallenrod and Pan Tadeusk, attention may be called to the poem Grażyna, which describes the adventures of a Lithuanian chieftainess against the Teutonic knights. It is said by Ostrowski to have inspired the brave Emilia Plater, who was the heroine of the rebellion of 1830, and after having fought in the ranks of the insurgents, found a grave in the forests of Lithuania. A fine classical Oriental piece is Farys. Very good too are the odes to Youth and to the historian Lelewel; the former did much to stimulate the efforts of the Poles to shake off their Russian conquerors. It is enough to say of Mickiewicz that he has obtained the proud position of the representative poet of his country; her customs, her superstitions, her history, her struggles are reflected in his works. It is the great voice of Poland appealing to the nations in her agony.

His son, Ladislas Mickiewicz, wrote Vie d'Adam Mickiewicz (Posen, 1890-1895, 4 vols.), also Adam Mickiewicz, sa vie et son œuvre (Paris, 1888) Translations into English (1881-1885) of Konrad Wallenrod and Pan Tadeusk were made by Miss Biggs. See also Œuvres politiques de Mickiewicz, trans. by Christien Ostrowski (Paris, 1843).

MICKLE, WILLIAM JULIUS (1735-1788), Scottish poet, son of the minister of Langholm, Dumfries-shire, was born on the 28th of September 1735. He was educated at the Edinburgh high school, and in his fifteenth year entered business as a broker. His father purchased the business, and on his death William Mickle became the owner; but he neglected his affairs, devoting his time to literature, and before long became bankrupt. In 1765 he went to London, where in 1765 he published "a poem in the manner of Spenser" called the Combawine (afterwards Sir Martyn); was appointed corrector to the Clarendon Press, and translated the Lusiad of Camoens into heroic couplets (specimen published 1771, whole work, 1775). So great was the repute of this translation that when Mickle—appointed secretary to Commodore Johnstone—visited Lisbon in 1779, the king of Portugal gave him a public reception. On his return to London he was appointed one of the agents responsible for the distribution of pamphlets, and this employment, in addition to the sums brought him by his translation of the Lusiad, placed him in comfortable circumstances.

It has been suggested that the Scottish poet "There's nae luck about the hoose" was Mickle's. It is more likely, however, that Jean Adams was the author. Scott read and admired Mickle's poems in his youth, and founded Kenilworth on his ballad of Cumnor Hall, which appeared in Thomas Evans's Old Ballads . . . with some of Modern Date (1784).

MICMAC, a tribe of North American Indians of Algonquin stock. They formerly occupied all Nova Scotia, Cape Breton and Prince Edward Island, New Brunswick, and Newfoundland. They fought on the French side in the colonial wars. They are now civilized and almost all profess Catholicism. They number some 4000 in settled communities throughout their former territory.

There is an excellent account of the Micmac Indians in J. G. Millais's New Brunswick and its Unravelled Ways (1868).

MICON, a Greek painter of the middle of the fifth century B.C. He was closely associated with Polygnotus of Thasos, in conjunction with whom he adorned the Painted Stoa, at Athens, with paintings of the battle of Marathon and other battles. He also painted the Erechtheum at Athens.

MICROCLINE, a rock-forming mineral belonging to the feldspar group (see FELSpar). Like orthoclase it is a potashfeldspar with the formula KAlSi3O8, but differs from this in crystallizing in the anorthic system. The name (from Greek μικρός, small, and κλίνειν, to incline) was given by A. Breithaupt in 1830, and has reference to the fact that the angle (86° 30') between the two perfect cleavages differs but little from a right angle: the species was, however, first definitely established by A. Des Cloizeaux in 1876. The crystals and cleavage masses are transparent to strongly translucent; their colours are white, colourless, or bluish grey, and specific gravity (3-26) are the same for the two minerals; there are, however, important differences in the twinning and in the optical characters. In addition to being twinned according to the same laws as orthoclase, microcline is repeatedly twinned according to the albite-law and the pericline-law, producing a very characteristic grating or cross-hatched structure which is especially prominent when thin sections of the mineral are examined in polarized light. This lamellar structure is often on a very minute scale, sometimes so minute as to be almost indistinguishable: it has therefore been suggested that orthoclase is really a microcline in which the twin-lamellae are ultra-microscopic. In a section parallel to the basal plane c (001) of a microcline crystal the lamellae do not extinguish optically parallel to the edge b as in orthoclase, but at an angle of 15° 30'; further, the obtuse bisectrix of the optic axes in microcline is inclined to the normal of the plane b (010) at an angle of 15° 26'. Green microcline is distinctly pleochroic.

Microcline occurs, usually with orthoclase, as a constituent of pegmatites, granites and gneisses; it is rare in porphyries and is not known in volcanic rocks. A beautiful crystallized variety occurs on the banks of the river Sabrina, a bright green variety known as amazonite (q.v.). Chesterite is a variety occurring as crystals on dolomite in Chester county, Pennsylvania.

Closely allied to microcline is the anorthic soda-potash-feldspar known as anorthoclase or natron-microcline. Here sodium predominates over potassium and a little calcium is also often present, the formula being (NaK)AlSi3O8. It resembles microcline in having a cleavage angle of very nearly 90° and in the cross-hatched structure, the latter being usually very minute and giving rise to a mottled
MICROCOMPACTION—MICROMETER

It is the characteristic field of volcanic rocks which are tumbled in soda, in water, and the lavas of the island of Pantelleria near Sicily and those of Kilimanjaro and Mount Kenya in East Africa: the rhomb-shaped porphyritic fields of the "rhomb-porphry" of southern Norway also belong here. (L. & J. S.)

MICROCOMPACTON, a term often applied in philosophical and in general literature to man regarded as a "little world" (Gr. μικροσ κόσμος) in opposition to the "macrocosm," great world, in which he lives. From the dawn of speculative thought in Greece the analogy between man and the world has been a common-place, and may be traced from Heraclitus and Empedocles, through Plato, Aristotle, the Stoics, the Schoolmen and the thinkers of the Renaissance down to the present day. Thus Lotze's comprehensive survey of mental and moral science is termed the "systema monadologicum" (1643-1667) of which the tendency indicated by the term is the monadology of Leibnitz, in which the monad is regarded as containing within its own closed sphere an expression of the universe, the typical created monad being the human soul.

MICROCOMPOUND, or ammonium sodium hydroxide, NH₄NaHPO₄, 410, so named by the alchemists because it is contained in the decomposing urine of man (the "microcosm"). It is interesting historically as being the raw material from which Brand prepared phosphorus, whence it is derived the name of salt phosphorus, a term still used in laboratory practice.

The true microcosm of the sun, however, lies in large transparent crystals from a mixture of solutions of sal-ammoniac and disodium phosphate, or by saturating a solution of monosodium phosphate with ammonia. When heated to redness, it leaves a transparent glass of sodium metaphosphate, Na₅P₃O₁₀, which like borax dissolves most metallic oxides, with formation of glasses that often exhibit characteristic colours, and which may be used in the qualitative analysis of substances. (See CHEMISTRY, § Analytical.)

MICROMETER (from Gr. μικροσ, small, μετρον, a measure), an instrument applied to telescopes and microscopes for measuring small angular distances with the former or the dimensions of small objects with the latter.

Before the invention of the telescope the accuracy of astronomical observations was necessarily limited by the angle that could be distinguished by the naked eye. The angle between two objects, such as stars or the opposite limbs of the sun, was measured by directing an arm furnished with fine "sights" (in the sense of the "sights" of a rifle) first upon one of the objects and then upon the other (q.v.), or by employing an instrument having two arms, each furnished with a pair of sights, and directing them against a pair of sights upon one object and the second pair upon the other. The angle through which the arm was moved, or, in the latter case, the angle between the two arms, was read off upon a finely graduated arc. With such means no very high accuracy was possible. Archimedes concluded from his measurements that the sun's diameter was greater than 27° and less than 32°; and even Tycho Brahe was so misled by his measures of the apparent diameters of the sun and moon as to conclude that a total eclipse of the sun was impossible. Michael Maestlin in 1579 determined the relative positions of eleven stars in the Pleiades (Historia coelestis Lucii Becatti, Augsburg, 1666), and A. Winnecke has shown (Monthly Notices R.A.S., xxxix. 146) that the probable error of these measures amounted to about ± 0.5°.

The invention of the telescope at once extended the possibilities of accuracy in astronomical measurements. The planets were shown to have visible disks, and to be attended by satellites whose distance and position angle relative to the planet it was desirable to measure. It became, in fact, essential to invent a 1 micro-metre [1] for measuring the small angles which were for the first time rendered measurable. There is now no doubt that William Gascoigne, a young gentleman of Yorkshire, was the first inventor of the micrometer. William Crabtree, a friend of his, taking a journey to Yorkshire in 1639 to see Gascoigne, writes thus to his friend Jeremiah Horrocks: "The first thing Mr Gascoigne showed me was a large telescope amplified and adorned with a few inventions of his own, whereby he can take the diameters of the fixed stars or any small angle in the heavens or upon the earth, most exactly and completely. And the great part of the micrometer so mentioned fell into the possession of Richard Townley of Lancashire, who exhibited it at the meeting of the Royal Society held on the 25th of July 1667.

The principle of Gascoigne's micrometer is that two pointers having parallel edges at right angles to the measuring screw, are moved in opposite directions and set symmetrically at the right angles to the axis of the telescope. The micrometer is at zero when the two edges are brought exactly together. The edges are then separated till they are tangent to the opposite limbs of the disk of the planet to be measured, or till they respectively bisect two stars, the angle between which is to be determined. The symmetrical separation of the edges is produced and measured by a single screw; the fractions of a revolution of the screw are obtained by an index attached to one end of the screw, reading on a dial divided into 100 equal parts.

The whole arrangement is elegant and ingenious. A steel cylinder (about the thickness of a goose-quill), which forms the micrometer screw, has two threads cut upon it, one-half an inch behind the double the pitch of the other. This screw is mounted on an oblong box which carries one of the measuring edges; the other edge is mounted on the box which carries the other edge of the screw relatively to the edge attached to the box, whilst the box itself is moved parallel to the axis of the telescope by the finer screw. This produces an opening and closing of the edges symmetrically with respect to the telescope axis. Planets, stars and the first vaults of the sky are all measured to the accuracy of 30000. The micrometer is a small instrument, and the complexity of the work required the greatest care. The first micrometer was made by William Mauin, in 1667, for Edmund Halley, one of the first to appreciate the value of the instrument for the study of the moon. The micrometer was afterwards improved by Gaspard de Prony, who made it the distinguishing mark of his observatory at Bologna, and by the French Instrument-maker, Le Verrier, who made it the mark of his observatory at Paris.

The micrometer was used by Astronomers of all nations for the measurement of stars, planets and other celestial objects. The most celebrated micrometers are those of Gascoigne, of Borelli, and of William Maclaurin. The micrometer of Gascoigne was used by James Bradley in his investigation of the parallax of the fixed stars, and by William Herschel in his investigation of the parallax of the fixed stars. The micrometer of Borelli was used by Galileo in his investigation of the parallax of the fixed stars, and by William Herschel in his investigation of the parallax of the fixed stars. The micrometer of Maclaurin was used by James Bradley in his investigation of the parallax of the fixed stars, and by William Herschel in his investigation of the parallax of the fixed stars.

The micrometer of Gascoigne was used by James Bradley in his investigation of the parallax of the fixed stars, and by William Herschel in his investigation of the parallax of the fixed stars. The micrometer of Borelli was used by Galileo in his investigation of the parallax of the fixed stars, and by William Herschel in his investigation of the parallax of the fixed stars. The micrometer of Maclaurin was used by James Bradley in his investigation of the parallax of the fixed stars, and by William Herschel in his investigation of the parallax of the fixed stars.

Delambre gives the following comparison between the results of Gascoigne's measurements of the sun's semi-diameter and the computed results from modern determinations:

Gascoigne, from his observations, deduces the greatest variation of the apparent diameter of the sun to be 3°, according to the Connaissance des temps it amounts to 32°. These results prove the enormous advance attained in accuracy by Gascoigne, and his instrument is a milestone in the development of the telescope.

Huygens, in his Systema Saturnium (1659), describes a micrometer with which he determined the apparent diameters of the principal planets. He inserted a slip of metal, of variable breadth, at the focus of the telescope, and observed at what part it exactly covered the object under examination; knowing the focal length of the telescope and the width of the slip at the point observed, he thence deduced the apparent angular breadth of the object. The Marquis Malvasia in his Epithemerides (Bologna, 1662) describes a micrometer of his own invention. At the focus of his telescope he placed fine silver wires at right angles to each other, which, by their intersection, formed a network of small squares. The mutual distances of the intersecting wires he determined by counting, with the aid of a pendulum clock, the number of seconds required by an equatorial star to pass from west to east, while the telescope was adjusted so that the star ran parallel to the wires at right angles to those under investigation. In the Phil. Trans. (1667), No. 21, p. 373, Adrien Auzout gives the results of some measures of the diameter of the sun and moon made by himself, and this communication led to the letters of Townley and Bevis above referred to. The micrometer of Auzout and Picard was provided with silk fibres or silver wires instead of the edges of Gascoigne, but one of the silk fibres remained fixed while the other was moved by a screw. It is beyond doubt that Huygens independently discovered that an object placed in the common focus of the two lenses of a Kepler telescope appears as distinct and well-defined as the
image of a distant body; and the micrometers of Malvaison, Auzout and Picard are the natural developments of this discovery. Gascoigne was killed at the battle of Marston Moor on the 2nd of July 1644, in the twenty-fourth year of his age, and his untimely death was the first double blow to the cause of the telescope. But the publication of the discovery which anticipated, by twenty years, the combined work of Huygens, Malvaison, Auzout and Picard in the same direction.

As the powers of the telescope were gradually developed, it was found that the finest hairs or filaments of silk, or the thinnest silver wires that could be drawn, were much too thick for the refined purposes of the astronomer, as they entirely obliterated the image of a star in the more powerful telescopes. To obviate this difficulty Felice Fontana (in his 'Saggio di fisica e di storia naturale', 1755) first proposed the use of spider webs in micrometers, but it was not till the attention of Troughton had been directed to the subject by Rittenhouse that the idea was carried into practice. In 1813 Wollaston proposed fine platinum wires, prepared by surrounding a platinum wire with a cylinder of silver, and drawing out the cylinder with its platinum axis into a fine wire. The surrounding silver was then dissolved by nitric acid, and a platinum wire of extreme fineness remained. But experience soon proved the superiority of the spider web; its perfection of shape, its lightness and elasticity, have led to its universal adoption.

Beyond the introduction of the spider line it is unnecessary to mention the various steps by which the Gascoigne micrometer assumed the modern forms now in use, or to describe in detail the suggestions of Hooke, Wren, Smeaton, Cassini, Bradley, Maskelyne, Herschel, Arago, Pearson, Bessel, Struve, Dawes, &c., or the successive productions of the great artists Ramsden, Troughton, Fraunhofer, Emet, Simms, Cooke, Grubb, Clarke and Repsold. It will be sufficient to describe those forms with which we are more immediately concerned, those that have been done, or which have survived the tests of time and experience.

Before astronomical telescopes were mounted parallactically, the measurement of position angles was seldom attempted. Indeed, in those days, the difficulties attached to such measures, and to the measurement of distances with the filar micrometer, were exceedingly great, and must have taxed to the utmost the skill and patience of the observer. For, on account of the diurnal motion, the direction of the axis of the telescope when pointed to a star is always changing, so that, to follow a star with a parallactic mounting, the observer requires to move continuously the two handles which give slow motion in altitude and azimuth.

Sir T. Young, in his 'Phil. Trans.' (1781), lixxi, 500. It was used by him in his earliest observations of double stars (1779-1783); but, even in his hands, the measurements were impracticable because of the difficulties. He had to encounter from the want of a parallactic mounting. In the case of close double stars he estimated the distance in terms of the disk of the components. For the measurement of wider stars he invented his lamp-micrometer, in which the components of a double star observed with the right eye were made to coincide with two lucid points placed ft. from the left eye. The distance of the lucid points was the tangent of the magnified angles subtended by the stars to a radius of 10 ft. This angle, therefore, divided by the magnifying power of the telescope gives the real angular distance of the centres of a double star. With a power of 400 the scale was a quarter of an inch for every second.

The Modern Filar Micrometer.

When equatorial mountings for telescopes became more general, no filar micrometer was considered complete which was not fitted with a position circle. The use of the spider line or filar micrometer became universal; the methods of illumination were improved; and micrometers with screws of previously unheard of fineness and accuracy were produced. These facilities, coupled with the wide and fascinating field of research opened up by Sir William Herschel’s discovery of the binary character of double stars, gained an impulse.

Micrometric research which has continued unabated to the present time. A still further facility was given to the use of the filar micrometer by the introduction of clockwork, which caused the movements of the micrometric micrometer to the motion of a star, and left the observer’s hands entirely at liberty.

The micrometer represented in figs. 1, 2, 3 is due to Troughton. Fig. 1 is a horizontal section in the direction of the axis of the tele-

became universal; the methods of illumination were improved; and micrometers with screws of previously unheard of fineness and accuracy were produced. These facilities, coupled with the wide and fascinating field of research opened up by Sir William Herschel's discovery of the binary character of double stars, gained an impulse.

Micrometric research which has continued unabated to the present time. A still further facility was given to the use of the filar micrometer by the introduction of clockwork, which caused the movements of the micrometric micrometer to the motion of a star, and left the observer's hands entirely at liberty.

The micrometer represented in figs. 1, 2, 3 is due to Troughton. Fig. 1 is a horizontal section in the direction of the axis of the tele-

scope. The eyecup ab consists of two plane-convex lenses a, b, of nearly the same focal length, and with the two convex sides facing each other. They are placed at a distance apart less than the focal length of a, so that the wires of the micrometer, which must be distinctly seen, are beyond b. This is known as Ramsden’s eyecup, having been made originally by him. The eyecup slides into the tube cd, which screws into the brass ring ef, through two openings in which the oblong frame, containing the micrometer slides, passes. These slides are shown in fig. 2, and consist of brass ruling. Shown either faulted (or falsely called "fiddling") it is fatal to accurate measurement. One of the most essential points in a good micrometer is that all the webs shall be so nearly in the same plane as to be well in focus together under the highest powers used, and at the same time absolutely free from "fiddling." For measuring position angles a brass circle gh (fig. 3), fixed to the telescope by the screw h, has rack teeth on its circumference that receive the teeth of an endless screw w, which, being fixed by the arms xx to the lower box, gives the latter a motion of rotation round the axis of the telescope; an index upon this box points out on the graduated circle gh the angular rotation of the instrument.

The micrometer by Troughton, fitted to their 5 ft. equatorial telescope, is the first position micrometer constructed capable of measuring position angles to 10".

So far as we can ascertain, the first telescope of large size driven by clockwork was the 6-in. equatorial made for Struve at Dorpat by Fraunhofer; it was completed in 1825. The original idea appears to be due to L. Claudius; the design of the micrometer was published by D. Simms (Phil. Trans., 1812, p. 497). In 1757 he presented a telescope to the king, so accurately driven by clockwork that it would follow a star all night long.
The English micrometer still retains the essential features of Troughton's original construction as described. The later English artists have somewhat changed the mode of communicating motion to the slides, by attaching the screws permanently to the micrometer head and tapping each micrometer screw into its slot. Instead of making the slot or the face of the screw with the hollow cone, as in fig. 4, attached to the end of the micrometer, the French artists still retain Troughton's form.

The micrometer represented in fig. 5 is the original Merz micrometer of the Cape Observatory, made by Fraunhofer. S is the head of the micrometer screw proper, 3 that of the screw moved by the screw attached to the micrometer head. A fixed web is attached, s, that of a screw which moves the eyepiece E. C is the clamp and M the slow motion in position angle. L, L are tubes attached to a large tube N; the former has a long on. A strong hollow cylinder which terminates in the screw V. By this screw the whole apparatus is attached to the telescope. The nozzles of small lamps are inserted in the tubes L, L, for illumination, and placed at a convenient distance from the slit. These lamps are admitted through apertures in the strong hollow cylinder above mentioned (for illumination, see p. 385). In this micrometer the three slides moved by S, s, and s' are simple dovetails. The lowest of these slides repose upon a foundation-plate P, into one end of which the screw s is tapped. In the middle of this slide a stiffly fitting brass disk is inserted, to which a small turn-table motion may be communicated by an attached arm, acted on by two fine opposing screws accessible to the astronomer, and by their means a fixed web may be rendered strictly parallel with the movable one. Another web is fixed parallel to the axis of the screw, as nearly as possible in the same plane with it and passing through the axis of rotation of the micrometer. For the internal structural details of the micrometer the reader is referred to the article "Micrometer" in the 9th edition of the Encyclopaedia Britannica.

To use the instrument, it is well first to adjust the web moved by the screw S, so that its point of intersection with the web (commonly called the "position-web"), which is parallel to the axis of the screw, shall be nearly coincident with the axis of rotation of the micrometer box. For this purpose it is only necessary to direct the telescope to some distant object, bisect that object with the movable wire, and read the number of revolutions and parts of a revolution of the screw; now reverse the micrometer box 180° and repeat the observation; the mean of the two readings will be the point required. Now direct the telescope to a star near the equator and so that the star's image in its diurnal motion shall pass across the intersection of the two webs which mark the axis of rotation of the micrometer box. Then, as the diurnal motion causes the star-image to travel away from the axis of rotation, the micrometer box is rotated till the image of the star when at a considerable distance from the axis is bisected by the position-web. The micrometer box is now directed along the position-angle by the clamp C, the star again brought back to the axis, and delicate adjustment given in position-angle by the slow-motion screw M, till the star-image remains bisected whilst it traverses the whole length of the position-web by the diurnal motion only. This determines the reading of the position-circle corresponding to position-angle 90° or 270°.

The position-angles of double stars are reckoned from north through east, the brighter star being taken as origin. To observe the position-angle of a double star it is only necessary to turn the position-web so that it shall be coincident with the star, and join the centres of the components of the double star.

To test this parallelism the single web must be made to bisect the images of both components simultaneously, as in fig. 6, because it is evident that if the two components of the double star are not exactly in equal magnitude, there will be a great tendency to systematic error if the web is placed on one side or other of the star.

To avoid such error Dawes used double wires, not spider webs, placing the image of the star symmetrically between them. Other astronomers use the two distance-measuring webs, placed some distance apart, for position wires. This plan has the advantage of permitting easy adjustment of the webs to such a distance apart as may be found most suitable for the particular observation, but has the disadvantage that it does not permit the zero of the position-circle to be determined with the same accuracy; because, whilst by means of the screw s' (fig. 7) the eyepiece can be made to lie on the positon-web parallel to the screw, the bisected image of the star by a star moving by the diurnal motion at right angles to the micrometer screw can only be followed for a limited distance, viz., the field of the eyepiece.

But, as the angle between the position-web and the distance-webs is a constant, the remedy is to determine that angle (always very nearly a right angle) by any independent method and employ the distance-webs as position-webs in the way described, using the position-web only to determine the instantaneous index error of the position-circle.

To measure distances with the Fraunhofer micrometer, the position-circle is clamped at the true position-angle of the star-image, by the web, which is moved by the graduated head S. Next the star B is bisected by the fixed web and A by the movable wire, or vice versa, without disturbing the reading for coincidence of the wires. No one, unless he has previously worked without such an arrangement, can fully appreciate the advantage of bringing up a star to bisection by moving a micrometer with a delicate screw-motion, instead of having to change the direction of the screw. Thus the fixed wire can be set exactly on star A by the screw s, whilst star B is simultaneously bisected by the movable wire, or vice versa, without disturbing the reading for coincidence of the wires.

When it is further remembered that the earlier telescopes were not provided with the modern slow motion and that the Strves, in their extensive researches on the motion of double stars were greatly helped by the slow motion of the micrometer head, it is easy to understand the patience and skill which, with such means, led to such results. Dawes, who employed a micrometer of the English type (figs. 1, 2 and 3), used to bolt the head in the direction of the slow-motion screw. Thus the instrument was provided with a slipping piece, giving motion to the slow-motion screw, and also acting on two slides, one in right ascension, the other in declination, so that either of the wires could be placed upon either component of a double star with great advantage (Mem. R.A.S. xxxv. 19). The micrometer shown in fig. 8 was made by Repsold for the Cape Observatory. Fig. 9 represents the same type as that used in the Great Equatorial.

---

1 When it is remembered that the measurements of the Strves, Debnawski, Secchi, the Bonds, Maclaren, and many other astronomers have been made with Fraunhofer or Merz micrometers it is not too much to say that fig. 5 represents the instrument with which a half of the astronomical measurements of the 19th century were made.

2 For the corrections applicable to measures of position-angle in different hour angles, account of errors of the equatorial instrument and of refraction, see Chauvenet's Practical and Spherical Astronomy, ii. 392 and 450.
MICROMETER

The micrometer with the upper side of the box removed. The letters in the description refer to both figures.

The head of the micrometer screw, that of the screw by which the micrometer box is moved relative to the plate (fig. 8), s, that of the screw which moves the eyepiece slide. K is the clamp in position angle, b the dovetail, and screw for side clamp, R, R its two readers. The latter are in fact little microscopes carrying a vernier etched on glass, in lieu of a filar micrometer. These verniers can be read to 1', and estimated to 0.2. D is the drum-head which gives the fraction of a revolution, d that which gives the whole number of revolutions, I is the index or pointer at which both drums are read. This index is shown in fig. 9, but only its mode of attachment (X, fig. 9), in fig. 8. The teeth of the pinion, z, fig. 9, are cut on the axis of the micrometer screw. The drum d and its attached tooth wheel are ground to turn smoothly on the axis of the screw. The pinion z and the toothed wheel d are connected by an intermediate wheel and pinion V; the numbers of teeth in the wheels and pinions are so proportioned that twenty-four revolutions of the micrometer screw produce one revolution of the drum and wheel d. The divisions of both drums are conveniently read, simultaneously, by the lens e; at night the lamp which illuminates the webs and the position-circle also illuminates the drum-heads (see on illumination p. 385). aaaa is the web-frame (fig. 9), bbb is a single rod consisting of two cylinders accurately fitting in the ends of the micrometer box, the larger cylinder being at b. There is a hole in the web-frame which smoothly fits the larger cylinder at b, and another which similarly fits the smaller cylinder at γ. A spiral spring, c, wound on the cylinder γ, rests one end on the shoulder formed by the difference of the diameters of the cylinders b and γ, and the other on the inside of the web-frame, presses the latter continuously towards γ. Contact of the web-frame of the micrometer with the side of the box at γ would therefore take place, were it not for the micrometer screw. This screw fits neatly in the end of the box at e, passes loosely through the web-frame at i, is tapped into the frame at γ', and its end rests on a flat hardened surface at γ. Rotation of the web-frame about γγ is prevented by the heads of the screws at m; the head of the screw on the lower side of the frame reposes on the plane m, that on the upper side (fig. 9) touches lightly on the inner surface of the lid of the box. Such rotation can obviously be controlled within limits that need not be further considered. But freedom of rotation in the plane of the paper (fig. 9) is only prevented by good fitting of the holes b, γ', and, since the weight of the slide is on one side of the screw, mist fit here will have the effect of changing the reading for coincidence of the movable with the fixed web in reverse positions of the micrometer. With the Cape micrometer a systematic difference has been found in the coincidence point for head above and head below, amounting to 0.14. This corresponds, in the Cape instrument, with an excess of the diameters of the holes over those of the cylinders of about 1/500 of an inch — a quantity so small as to imply good workmanship, though it involves a reading error which is much larger than the probable error of a single determination of the coincidence point. The obvious remedy is to make all measurements on opposite sides of the fixed web before reversing in position-angle—a precaution, however, which no careful observer would neglect. In measuring differences of declination, where the stars are brought up by the dural motion, this precaution cannot be adopted, because it is necessary always to bisect the preceding star with the fixed web. But in ΔΔ measures it is done by bisecting both stars with the same web (or different webs of known intervals fixed on the same frame), and not employing the fixed web at all. The uncertainty in zero, when known to exist, is really of no consequence, because the observations can be so arranged as to eliminate it.

The box is mounted on a strong hollow steel cylinder CC (fig. 9) by holes η, θ in the ends of the box, which fit the cylinder closely and smoothly. The cylinder is rigidly fixed in the studs C, C, and these are attached to the foundation plate f. The cylinder contains towards η a sliding rod, and towards θ a compressed spiral spring. There is thus a thrust outwards of the spring upon the hollow cap of the fixed spot C. A screwing in of θ thus causes the inner end of the rod to move towards η. Rotation of the box round CC is prevented by downward pressure of the spring Z on a projection attached to the side of the box. The amount of this pressure is regulated by the screw z.

The short screw whose divided milled head is a shifts the zero of the micrometer by pushing, without turning, the short sliding rod whose flat end forms the point d'appui of the micrometer screw at γ. The pitch of the screw is the same as that of the measuring screw (50 threads to the inch), and its motion can be limited by a stop to half a revolution.

The five fixed webs are attached to the table ηη, which is secured to the box by the screws p. The three movable webs are attached to the projections λλ on the frame u. The plane surfaces ηη and λλ are composed of a bronze of very close texture, which appears capable of receiving a finish having almost the truth and polish of an optical surface. It seems also to take a very clean V cut, as the webs can be laid in their furrows with an astonishing ease and precision. These furrows have apparently been cut in situ with a very accurate engine; for, notwithstanding the departure from parallelism can be detected in any of the movable webs relative to the fixed webs. Extraordinary care has evidently bestowed in adjusting the parallelism and distance of the planes η and λ, so that the movable wires shall almost, but not quite, touch the surface r. The vernish to fix the webs is applied, not on the surface r as is usual, but on a bevel for the purpose, the position of the webs depending on their tension to keep them in their furrows. The result is that no trace of "fiddling" exists, and the movable and fixed webs come sharply together in focus with the highest powers. Under such powers the webs can be brought into apparent contact with such precision and delicacy that the uncertainty of measurement seems to lie as much in the estimation of the fraction of the division of the head as in the accuracy of the contact. It is

a convenient feature in Repsold's micrometer that the webs are very near the inner surface of the top of the box, so that the eye is not brought inconveniently close to the plate when high powers are used.

Another excellent micrometer, originally based on a model by Clark of Cambridge, Massachusetts, has been largely used by Burnham and others in America. The form, as constructed by Warner and Swasey for the nebulae telescopes, is shown in figs. 10 and 11. The micrometer box, and of course with it the whole system of spider webs, is moved by the screw s, whilst the measuring web is independent W (attached outside the box), and a thrust of the rod instrument will be readily understood from the figure without further explanation. The method of counting the total number of revolutions gives more friction and is less convenient than Repsold's, and no doubt the micrometer head in the practical and convenient plan adopted by Repsolds.

Repsold's more recent form of the spider-line micrometer (since

The marks of varnish so applied will be seen in fig. 9. 

Fig. 9.

Fig. 10.
position-angle by the screw $K$ and slow motion in position-angle is given by the screw $s$. The small drum-head $T$ opposite the micrometer head $S$ turns a screw which acts upon a short cylinder that cannot turn but can move only in the direction of the axis of the micrometer screw. The end-plane of this cylinder receives the pressure of the micrometer screw, so that by turning the small drum-head the coincidence-reading of the movable web with the fixed web can be changed, and thus any given angle can be measured with different

of position-angle for his movable webs with the same accuracy as he formerly could only do for the so-called position-angle webs. Reisold also provide two insulated sliding contact rings instead of the single ring $g$, so that the electric current for illuminating the lamps does not pass through the instrument itself but may come to the micrometer from the storage battery through two insulated leads. The same firm is also constructing a micrometer in which the readings of the head are printed on a band of paper instead of being read off at the time of observation.

Instruments have been invented by Alvan Clark and Sir Howard Grubb for measuring with the spider-line micrometer angles which are larger than the field of view of the eyepiece. In both cases two eyepieces are employed, one to view each separate web. One drawback to this form of instrument is that the two webs cannot be viewed simultaneously, and therefore the observer must rely in the steadiness of rate of the clockwork and uniformity in the conditions of refraction whilst the eye is moved from one eyepiece to the other.

Clark's micrometer was exhibited at the June meeting of the Royal Astronomical Society in 1859 (Monthly Notices, R.A.S., vol. xix.). Grubb's duplex micrometer is described in the 9th edition of the Encyclopaedia Britannica. Some examples of use of the latter are given by Professor Prior in (Mem. R.A.S. xxvii. 4–12), who estimates the accuracy attainable with the duplex micrometer as equal to that of the heliometer, but as few measures of permanent value have been made with the instrument, and those made exhibit an accuracy far inferior to that of the heliometer, it is unnecessary to describe the instrument here in greater detail.

The Reading Micrometer-Microscopes. Micrometers used for subdividing the spaces on graduated circles and scales have, in general, only a single pair of cross-webs or parallel webs moved by a single screw. The normal form of the apparatus is shown in figs. 13 and 14. Of the objective, $D$ is the graduated head of the screw, $G$ the milled head by which the screw $g$ is turned, $A$ an eyepiece sliding in a tube $B$, $aa$ (fig. 14) the slide, and $b, b$ the spiral springs. The focal length of the objective and the distance between the optical centre of the lens and the webs are so arranged that images of the divisions are formed in the plane of the webs, and the pitch of the screw is such that the division of the scale corresponds with some whole number of revolutions of the screw.

There is what is technically called a "comb" inserted in the micrometer box at $d$ (fig. 14) below the surface of the webs. This comb does not move with reference to the box, and serves to indicate the whole revolution of which a fraction is read on the head. In fig. 14 a division is represented by cross webs, and five revolutions of the screw correspond with a division of the scale. In all modern reading micrometers the cross webs of fig. 14 are replaced by parallel webs embracing the division (fig. 15). The means for changing the length of the tube and the distance of $C$ from the scale are represented in the figure. These appliances are required if the "run" has to be accurately adjusted. By "run" is meant the difference between the intended whole number of screw-rotations and the actual measures of the space between two adjacent divisions of the scale in turns of the screw Fig. 15, divided by the number of intended revolutions. In delicate researches two divisions of the scale should always be read, not merely for increased accuracy but to obtain the corrections for "run" from the observations themselves.

Reisold employ for the micrometers of their reading microscopes the form of construction shown in fig. 9, omitting, of course, the motion of the whole micrometer box given by the screw $s$ for those cases in which the axis of the micrometer is supposed to remain constant in position, as, for example, in the case of the reading micrometers of transit circles (see TRANSIT CIRCLE).

But when the relative positions of two adjacent objects or scale-divisions have to be determined (as, for example, in the case of heliometer scales), much time is saved by retaining the motion of the micrometer box. One double web, fixed in the box, is pointed symmetrically, as in fig. 15, on one of the scales, by moving the whole micrometer box by means of the screw $S$; the pair of webs, moved by the screw $s$, is then pointed upon an adjacent division on the other scale. If the reading for coincidence of the movable with the fixed webs is known, we then obtain from the single reading of $S$ the difference from coincidence of the divisions of the two scales.
MICROMETER

It is generally possible so to arrange the method of observation as to eliminate the effect of an error in "the reading for coincidence of the webs" from the results. This excellent time-saving contrivance has also been used in Gill's apparatus for measuring astronomical plates (see below).

**Ghost Micrometer**—C. E. Burton and Sir Howard Grubb (Monthly Notices, xli, 99), after giving attention to J. von Lamont's paper ("Die Michelsonische Papierspiegelung", J. der Österr. Akad. d. Wiss. [II. Abt. 12], pp. 157 and K. L. von Littrow's paper (Proc. of Vienna Acad. of Sciences, xx. 253) on a like subject, proceed to describe a most ingenious form of "Ghost Micrometer," in which a thin line or semi-transparent plate, previously illuminated in a line direction, is thrown on the silvered plate, thereby providing a bright line of view. We have not had an opportunity of testing this, nor Grubb's more recent models; but, should it be found possible to produce such images satisfactorily, without distortion and with an apparatus convenient and rigid in form, such micrometers may possibly supersede the older micrometer. Their absolute freedom from distortion, the perfect control of the illumination and thickness of the lines, and the accuracy with which it will be possible to construct scales for zone observations will be important features of the new method.

**The Astronomic Micrometer or Measuring Machine.**—The application of photography to exact astronomy has created the necessity for new forms of apparatus to measure the relative positions of stellar and planetary images on photographic plates, and the relative positions of lines in photographic spectra.

Especially important has been the problem of measuring the "catalogue plates" of the international "Carte du ciel"—a work that implies the determination of the positions of some millions of stars—that is to say, of all stars to the 11th or 12th magnitude. The problem has been how to accomplish this work with the minimum of labour consistent with the desired accuracy. The adoption of a réseau photographed upon the plate has greatly facilitated the procedure. A plate of parallel-surfaced glass has a film of silver deposited upon it. On this film is ruled a system of lines 5 mm. apart, and another similar system of lines at right angles to the first, thus dividing the silvered surface of the plate into squares 5 mm. on the side. The cutter employed to rule these lines removes the silver in fine lines from the surface of the glass. Thus, if a photographic plate, before it is exposed in the telescope, is placed with its sensitive surface nearly in contact with the silvered surface of this réseau, and parallel light, normal to the surface of the plate, is allowed to fall on the silvered film through the glass on which the film has been deposited, that light will pass through the fine lines in the silver film where the silver has been removed by the cutter, but will otherwise be intercepted by the silver film. Thus a latent image of the réseau-lines will be formed on the photographic plate, and when this latter has been exposed to the sky in the telescope, we obtain, on development, a negative of the images both of the stars and of the réseau-lines. If the errors of the rectangular co-ordinates of these lines are known, the problem of determining the co-ordinates of any star-image on the plate becomes reduced to the comparatively simple one of interpolating the co-ordinates of the star relative to the sides of the 5 mm. square within which that image is included. This interpolation can, of course, be accomplished with the aid of a micrometer-microscope whose optical axis is normal to the plate, provided that the plate is mounted on slides which enable the observer to bring the réseau-squares successively under the microscope.

This system has an additional advantage beyond its convenience, viz., that if any distortion of the réseau during development, the same distortion will be communicated both to the star-images and to the réseau-lines, and consequently its effect will be eliminated from the resulting star co-ordinates, except in so far as the distortion is caused by the physical character of the plate itself. This exception is hardly worth consideration. An originally unanticipated difficulty has arisen from the fact that the réseau-lines have not been ruled on the glass, but on the silver film from which the silver has been removed by the cutter, the undeveloped photographic copy of the réseau may in such a case not be an exact reproduction of the silvered réseau. It is practically impossible to work with the sensitive film in contact with the réseau-film, not only because dust particles and contact would injure the silver film, but also because the plate-glass used is seldom a perfect plane. The discrepancies produced in this way are, however, very small, if care is taken to minimize the distance between the silver film and the photographic plate and to select a reasonably good piece of glass for the réseau. For very refined work, however, the irregularities in the reproduction of the réseau may be studied by comparing the measures of the original réseau with the mean of corresponding measures of a number of photographic copies.

At Greenwich, Oxford and several other observatories, instead of measuring the distances of the star's image from the opposite sides of the 5 mm. réseau-square by means of a spider-line micrometer, a conveniently graduated scale, on the plan shown in fig. 16, is employed in the common focus of the objective and the eyepiece. The image of the star is set upon the intersections of the lines of the central cross, and the positions of the images of the lines of the cross are determined by the use of the réseau with the micrometer of fig. 16. The scale of the réseau is fixed in this case at 90°, and its graduations are made at intervals of 1°.

For the construction of the réseau, it was found that the lines should be as accurate as the photographs from which they are taken. This was faciliated by the introduction of an improved system of "Gill's Spider-Line Micrometer". In this micrometer, the spider-line is employed to determine the positions of the lines of the réseau and of the images of the lines of the cross. This micrometer is of course capable of giving results of high precision, but the drawback is that the process involves a minimum of six pointings and the entering of six screw-head readings in order to measure the two co-ordinates of the star.

**Gill's Measuring Machine.**—Sir David Gill (Monthly Notices, R.A.S. lix. 61) devised a measuring machine which combines the rapidity of the réseau-circles with the accuracy of the spider-line micrometer and simplifies the reductions of the observations at the same time. The essential features of the instrument are these:

1. The object glass of the micrometer-microscope is placed midway between the plane of the photographic plate and the plane of the micrometer webs.

2. The micrometer is provided with a "fixed square" 5 mm. × 5 mm., the sides of this square being parallel to the spider webs 4° of arc apart; the size of the square is reckoned from centre to centre of these double webs.

---

**Fig. 16.**—Diagram of the diaphragm in eyepieces of the micrometer used for measuring the plates of the Astronomic Catalogue.

---

The two micrometer screws (X and Y, fig. 17), which actuate the movable slides, have heads divided into 100 parts, one revolution = 0.5 mm.; so that ten revolutions are = 5 mm., or = the interval between two adjacent reséau-lines, or = the interval between the sides of the "fixed square."

4. Two other screws, o, p, the heads of which are not graduated, give motions to the whole micrometer box through 1 mm. in directions parallel to the axes of the two micrometer screws.

5. Each of the two micrometer screws X and Y makes a system of six parallel webs, placed 4" of arc apart from each other. These webs serve not only for pointing on stars to determine their co-ordinates (in manner afterwards described), but also for estimating the diameters of the star-images in terms of these 4" intervals.

The apparatus has been used with complete success at the Royal Observatory, Cape of Good Hope, and at Melbourne, Sydney and Córdoba.

Effects of Wear on the Micrometer Screws.—The accuracy of this apparatus has been frequently criticized on the ground that errors are produced in the screws by the effect of wear. One reply to this is that it is not difficult to determine from time to time the errors of the screws and to apply the necessary corrections to the observations. But a little consideration will show that when the plate is reversed 180° the effects of errors of the screws produced by wear are practically eliminated.

In discussing the effect of wear upon a screw, it will be convenient to imagine the thread unrolled and forming a wedge, of which we can represent the unworn bearing-side by a straight line AB (fig. 18), identical for revolution ε and for 10-ε, and thus will disappear in their effect in the mean of observations made in reversed positions of the plate. At the Cape of Good Hope, after more than 200,000 pointings had been made, the screw-errors were re-determined; the results proved the truth of the above conclusions, viz. the absolute freedom of the derived co-ordinates from the effects of wear of the screws in the mean of measures made in reversed positions of the plate.

Hinks's Measuring Machine.—A very refined modification of the Cape machine is described by A. Hinks (Monthly Notices, R.A.S., vol. 61, p. 444), and the instrument contains many elegant mechanical and optical details due to Horace Darwin and Messrs Zeiss respectively.

Its fundamental principle is that, by a combination of glass scales with a micrometer screw, "the chief part of the distance to be measured is read off directly; the fractional part of the scale-space is not estimated but measured by the screw." Hinks claims that thus never more than one- or two-tenths of a revolution of the screw need be used in making the measurement, and little time is lost in running the screw backwards and forwards. All this is true, but three readings instead of one for each pointings, much more figure-work in computation (especially if corrections have to be applied to the scale-readings to reduce them to exact normal screw readings), are factors which involve a far greater expenditure of time than making a few additional turns of a screw in the process of measurement. Hinks's further claim that, in consequence of the small motion of the screw, less error is produced in the screw by wear is not true; for, although large movements of the screw produce a large amount of wear, that wear is spread over longer parts of the screw but remains the same for any particular revolution; the errors are exaggerated towards the extremity of the range of screw employed (see Monthly Notices, R.A.S., vol. 45, p. 83), and are therefore more likely to produce errors which are not eliminated when reversing all the plate in cases where the screw range is not strictly limited, and the wear therefore not strictly symmetrical.

The excellent manner in which the scales and micrometers are mounted, the employment of a compound microscope for viewing the scales, with its ingeniously arranged and admirably efficient reversing prism, and the perfection of its slow motions for focusing and reading, combine to render this a most accurate and useful instrument for very refined measures, although too slow for work in which the measures must depend on single pointings in each of two reversed positions of the plate, and where speed of working is essential.
photographic plate is fixed and the measuring microscope is
moved.

The chief drawback to type A is that the errors of the screw are
liable to change by wear, otherwise the apparatus, as made and
used, offers no inconvenience of any kind. In determining the
errors of the screw of the Potsdam form of micrometer plate it

was found that the observer imparts motion to the slide on which the travelling

web of the instrument is provided for, so that the observer can use the thumb and
finger of both hands in rotating it, there is no difficulty, after a little practice, in
keeping the web constantly bisecting the star in transit, and that with a little
practice he would be able to reduce the absolute errors in following the star
corresponding to known intervals from the line of collimation.

In the Astron. Nach., Vol. 88, 1901 Dr H. Struve published an account
of the application of clockwork as an aid in Repsold's method;
and, later, Dr Cohn published a more elaborate paper on the same
subject in the Astron. Nach., 3767. The method consisted in the
motion transmitted to the micrometer screw from an axis on which is
mounted a disk that presses with friction-contact upon a cone that
revolves uniformly by clockwork. The velocity of rotation of
the micrometer-screw could therefore be varied for stars of
different declination by varying the distance from the apex at
which the revolving disk presses upon the revolving cone.

In the Königstberg transit instrument used by Struve and Cohn, the
apparatus consists of a revolving rod which can be made to
correspond to the "imperial micrometer." This method of observation was
very successfully employed, under Seeliger at Munich, in an
extension of the work of measuring the diameter of the sun, under the auspices of
the Geodetic Institute at Potsdam, in telegraphic longitude
operations. Still more recently the method has been largely employed
at the Cape of Good Hope, and other observatories, and it is
impossible to say whether it is by the clockwork method, or by the
"imperial micrometer," or some other form, that the observations
are carried out at the Cape of Good Hope and elsewhere.

In the apparatus of type B as made by Zeiss there are two
microscopes attached to a lathe-plate, one of which views the
spectrum-plate (or other object) to be measured, while the other
views a scale that moves with the slide on which the spectrum-
plate is mounted. In this way the scale can be viewed by a micro-
scope of much higher magnifying power than can be employed
for the photographed spectrum. Indeed, if the scale were sub-
divided by \( \frac{1}{100} \) mm, the power employed might only be limited by
the sharpness of the division-lines. But for refined work this
would imply the investigation of too many divisions of the scale;
it is therefore more usual to divide the scale into single millimetres
or half-millimetres and to provide a micrometer which subdivides
the millimetre into 1000 or, by estimation, into 10,000 parts.

For very accurate work it is desirable that the base-plate, the slide
and the scale should be of nickel steel, having the same thermal
coefficient of expansion as glass.

The forms of measuring micrometers of type C, often seen in physical
laboratories, should be at once rejected for refined measurements,
because it is impossible to construct slides of such perfection that
the axis of the micrometer will remain absolutely normal to the
surface of the plate (assumed to be a plane) throughout the range
of measurement. Even if the slide itself is mechanically perfect,
the irregularity in the thickness of the lubricating oil between the
bearing surfaces of the slide is apt to produce a variable error.

Bakhuyzen (Bulletin de Com. perm. congres, astrog., i. 164) de-
scribed a measuring-machine by Repsold, in which the micrometer-
measuring screw is placed in a lathe-plate, one of which views the
Laplacian of the chiro-plate or object on which it moves,
so that it can view either a graduated scale or the photographic
plate. We have, in fact, in this instrument a combination of types
B and C. Even in this apparatus if the slide on which the chiro-
plate moves is not perfectly horizontal, the amount of the axis
of the microscope is liable to change in the course of movement
of the slide, and thus equal spaces on the scale will not be repre-

tended by equal spaces on the plate under measurement.

This remedy proposed by Repsold is not altogether a failure for the
whole slide to tilt instead of the microscope only; this would prove
a complete remedy.

The Travelling Wire Micrometer.—An important modern
application of the micrometer, which is not dealt with in the
article TRANSIT CIRCLE, is that which is now called "the
travelling wire micrometer." In the Astronomische Nachrichten, No. 2940, Dr Repsold proposed a method of meridian observing which consists in causing a web to
follow the image of a star in transit by motions communicated by
the observer's hands alone, whilst electrical contacts on the drum
of the micrometer screw register the chronograph the instants corresponding to known intervals from the line of collimation.

The purpose of his paper was to show that if the axis, by which the
observer imparts motion to the slide on which the travelling web
of the instrument is provided for, so that the observer can use the thumb and
grip of both hands in rotating it, there is no difficulty, after a little practice, in
keeping the web constantly bisecting the star in transit, and that with a little
practice he would be able to reduce the absolute errors in following the star
corresponding to known intervals from the line of collimation.

In the Astron. Nach., No. 3377, Repsold gives a detailed
description of two forms of meridians, fitted with means of observing in this manner, to which he gives the names of "the
impersonal micrometer." This method of observation was very
successfully employed, under Seeliger at Munich, in an
extension of the work of measuring the diameter of the sun, under the auspices of
the Geodetic Institute at Potsdam, in telegraphic longitude
operations. Still more recently the method has been largely employed
at the Cape of Good Hope, with other observatories, and it is
impossible to say whether it is by the clockwork method, or by the
"imperial micrometer," or some other form, that the observations
are carried out at the Cape of Good Hope and elsewhere.

In the apparatus of type B as made by Zeiss there are two
microscopes attached to a lathe-plate, one of which views the
spectrum-plate (or other object) to be measured, while the other
views a scale that moves with the slide on which the spectrum-
plate is mounted. In this way the scale can be viewed by a micro-
scope of much higher magnifying power than can be employed
for the photographed spectrum. Indeed, if the scale were sub-
divided by \( \frac{1}{100} \) mm, the power employed might only be limited by
the sharpness of the division-lines. But for refined work this
would imply the investigation of too many divisions of the scale;
it is therefore more usual to divide the scale into single millimetres
or half-millimetres and to provide a micrometer which subdivides
the millimetre into 1000 or, by estimation, into 10,000 parts.

For very accurate work it is desirable that the base-plate, the slide
and the scale should be of nickel steel, having the same thermal
coefficient of expansion as glass.

The forms of measuring micrometers of type C, often seen in physical
laboratories, should be at once rejected for refined measurements,
because it is impossible to construct slides of such perfection that
the axis of the micrometer will remain absolutely normal to the
surface of the plate (assumed to be a plane) throughout the range
of measurement. Even if the slide itself is mechanically perfect,
the irregularity in the thickness of the lubricating oil between the
bearing surfaces of the slide is apt to produce a variable error.

Bakhuyzen (Bulletin de Com. perm. congres, astrog., i. 164) de-
scribed a measuring-machine by Repsold, in which the micrometer-
measuring screw is placed in a lathe-plate, one of which views the
Laplacian of the chiro-plate or object on which it moves,
so that it can view either a graduated scale or the photographic
plate. We have, in fact, in this instrument a combination of types
B and C. Even in this apparatus if the slide on which the chiro-
plate moves is not perfectly horizontal, the amount of the axis
of the microscope is liable to change in the course of movement
of the slide, and thus equal spaces on the scale will not be repre-

tended by equal spaces on the plate under measurement.

This remedy proposed by Repsold is not altogether a failure for the
whole slide to tilt instead of the microscope only; this would prove
a complete remedy.

The Travelling Wire Micrometer.—An important modern
application of the micrometer, which is not dealt with in the
article TRANSIT CIRCLE, is that which is now called "the
travelling wire micrometer." In the Astronomische Nachrichten, No. 2940, Dr Repsold proposed a method of meridian observing which consists in causing a web to
follow the image of a star in transit by motions communicated by
the observer's hands alone, whilst electrical contacts on the drum
of the micrometer screw register the chronograph the instants corresponding to known intervals from the line of collimation.

The purpose of his paper was to show that if the axis, by which the
complex spectra of stars of the solar type this is by no means the case; for, as Dr. Hartmann remarks, "in the first place the lines in these spectra are so numerous that their complete measurement and reduction would require many days, and in the second place a rigorous reduction of such material has hitherto not been at all possible because the wave-lengths of the lines are not known with sufficient accuracy. On this account, observers have until now limited themselves to a partial treatment of such spectra, measuring only a small number of lines, whereby the major part of the rich material present in the plate remains unutilized." But the spectroscopes that can be employed for stellar spectrographs are not sufficiently powerful to separate fully lines which are very closely adjacent, and therefore a line, assumed to be of a known wave-length, may be apparently displaced by the near neighbourhood of an unknown line. Hartmann overcame these and many other difficulties by directly superposing the image of the spectrogram of a star, having iron comparison lines, upon the image of a spectrogram of the sun taken also with iron comparison lines.

The apparatus for this purpose is shown in fig. 21, its principle of construction is shown in figs. 22 and 23. The solar spectrograph is attached by clamps to the plate A, the stellar spectrograph to the plate A'. The plate A is mounted on the dove-tailed slide B, upon the metallic stage T, and can be moved to right or left relative to T by the micrometer-screw S; whilst the plate A' is mounted on the dove-tailed slide B' and can be moved at right angles to its greatest length by the screw G. The micrometer-screw S has a pitch of 0.5 mm., its head is divided into 100 parts. Two spiral springs underneath press the plate B with its agate end-bearing against the rounded end of the screw S. The whole number of revolutions of the screw is read by the scale X (fig. 23). The whole stage T, carrying both spectrograms, can be moved from right to left on the steel cylinder Z, by turning the head K, on the axis of which is a pinion that gears into a toothed rack attached to the lower side of the cylinder Z. A scale N on the cylinder Z serves for setting the slide to any required position. The preliminary conditions of measurement are:

1. The centre of both spectrographs shall be parallel to the axis of the cylinder Z.
2. The distance between the centres of the two spectrographs shall be equal to the distance between the optical axes of the two viewing microscopes.
3. The scales of the images formed in the focus of the eyepiece common to both microscopes shall be identical.

To fulfill condition (1) the plates A and A' are mounted in circular slides, whose centres are E1 and E2 respectively, so that by means of the screws D1, D2, with their corresponding opposing springs F1 and F2, the operation can be very easily accomplished. To fulfill condition (2) the two microscopes whose object glasses are O1 and O2 (fig. 22) are attached to the plate L, their optical axes being normal to the stage T. The screw Q serves to adjust the axis of O2 to coincidence with the centre of the lines of the solar spectrograph, and the screw G then serves to move the slide B1 till the optical axis of O1 is coincident with the centre of the lines of the stellar spectrograph. Suppose now the solar spectrogram to be viewed in the focus of O1, and the converging rays to be reflected by the prisms P1 and P2, till an image is formed in the focus of the eyepiece at the point where the axis of the eyepiece intersects...
the upper face of the prism \( P_2 \). Then if the prism \( P_2 \) is cemented to \( P_1 \) a sharp image of such lines of the solar spectrograph as are visible in the field of view will be seen in the eyepiece. If the stellar spectrograph is viewed in the focus of \( O_3 \) and the converging rays are reflected by the prism \( P_3 \) to \( P_4 \), no image would be seen in the eyepiece, for the rays would pass out directly through the parallel glass plate which is formed by the cementing together of the prisms \( P_1 \) and \( P_4 \). But if the cemented face of \( P_1 \) is silvered, then the lines of the stellar spectrogram would be seen in focus of the eyepiece and the image of the solar spectrograph would be obliterated. Therefore, if one-half of the cemented face of \( P_1 \) is silvered, it becomes possible to view, side by side, one-half of the image of the solar spectrograph formed by \( O_3 \) and one-half of the image of the stellar spectrograph formed by \( O_2 \). A prism half silvered in this way is provided, which enables the observer to compare the equality of scale of both photographs. If, for example, it is found that the image of the solar spectrograph is the larger of the two it becomes necessary to adjust the object glass \( O_2 \) farther from the stellar spectrograph. This has the effect of forming the image of the latter farther from the observer's eye, and so it becomes necessary to turn the handle of the rack-pinion \( V \) in such a way as to move the prisms \( P_3 \) and \( P_4 \) nearer to \( P_2 \) till the lines of the stellar spectrograph are again sharply in focus. The effect of turning the pinion \( V \) is, of course, to displace the focus both of the solar and stellar spectrographs in the field of the eyepiece, but this displacement is easily restored by the focussing screws \( O_3 \) and \( O_4 \). By successive adjustments of this kind condition (3) can be accurately realized.

These three adjustments having been made, the prisms \( P_3 \) and \( P_4 \) are removed and replaced by another prism in which the silvering is arranged as in fig. 24, where the hatched lines denote the silvered surfaces. The narrow tongues of the silvered surface will now reflect corresponding parts of the star-spectrogram, and will obliterate corresponding parts of the solar spectrograph—as shown in figs. 25 and 26. Fig. 25 shows the stellar and solar lines of the two spectrographs in coincidence, whilst the metallic lines of comparison are non-coincident. Fig. 26 shows the metallic lines of comparison in coincidence whilst the solar and stellar lines are non-coincident. It is obvious that these two conditions can be produced at the will of the observer by simply turning the screw \( S \), and that the difference of the readings of the screw-head, which are required to reproduce the two conditions in question, gives a measure of the displacement of the stellar lines relative to the solar lines. If then the screw-value in kilometres per second is known for the neighbourhood of each of the comparison lines employed, the radial velocity of the star can be independently derived directly from coincidences made in above manner in the neighbourhood of each comparison line. For the special purpose of determining the solar parallax this instrument has been used in a most refined and perfect manner by Dr Halm at the Cape of Good Hope (Annals of the Cape Observatory, vol. x. part 3).

**MICRONESIA**

From Zeitschr., für Instrumentenkunde, by permission of Julius Springer, Berlin.

**FIG. 25.**

Double Image Micrometers are described in the article HELIOMETER (q.v.).

**MICRONESIA** (from Gr. µικρός, small, and νῆσος, island), one of the three great divisions of the oceanic islands in the central and western Pacific. Lying to the north of Melanesia, it embraces the following groups: Mariana, Palaus, Caroline, Marshall and Gilbert. See articles under these headings, and PACIFIC OCEAN (section on Islands).

The Micronesian islands form in the main a branch of the Polynesian race, but distinguished from it by well-marked differences in appearance, language and institutions. Many of the islanders, however, show signs of hybridism. The proximity of Japan and the Philippines\(^1\) on the west, and of the Papuan

\(^1\)There are authenticated instances of Japanese junks, with living people in them, having been found in various parts of the North Pacific. In 1814 the British brig "Forster" met with one off the coast of California (about 36° N. lat.), with three living men and fourteen dead bodies on board. In December 1832 a Japanese junk arrived at the Hawaiian Islands with four of the crew living. If these junks could cross the Pacific in the latitude of Hawaii it is not at all unlikely that others running in a south-easterly direction would reach some of the many atolls which stretch over about 35° of longitude, forming the Caroline and Marshall archipelagoes.

The traditions of the Gilbert Islanders tell us that their islands
and South Polynesian islands on the south and south-east, suggests, what in fact is found, a combination of races. In some places the oblique Mongolian eye is noticed, and (together with certain Indo-Chinese customs) there is often a scantiness of beard and general "Malay" look, which increases westwards, and seems to imply relations with the archipelago subsequent to the departure thence of the pure Polynesians. In the Gilberts the traces of Polynesian (Samoan) influences are evident, and are confirmed by tradition. Among the Carolines and the Marshalls darker and more savage communities are found, suggesting a Melanesian element, which is further traceable in the Ellice and the Southern Gilberts.

Each of the four main groups, viz. the Caroline, Marshall, Gilbert and Ladrone (Mariana), from long isolation, has developed ethnological peculiarities of its own. The most advanced folk were the "Chamarros" of the Ladrone, owing to the greater natural resources of the islands, and perhaps more frequent contact with influences from the west; but as a separate people they no longer exist, having been nearly exterminated by the Spaniards in the 17th century. Next in advancement come the Carolines, generally the best equipped of all the Micronesians, with good houses, and well-proportioned rather squat figures. The archipelagoes of, nearly equally built, with small and regular features; head high and well proportioned, but forehead rather retreating and narrow at the temples; cheek bones and chin slightly prominent; straight black hair, longer than that of the Polynesians, color somewhat darker than the Polynesians, the Marshalls being darker and more vigorous than the Carolines, while the Gilbert type, though smaller than the latter, is still darker and coarser. The upper class greatly surpasses the common people in physique and intelligence.

There is a division of society into four to five classes, the membership of which is a hereditary right, and the status of the person is determined by his position in this scale. These classes must not intermarry, and when two islands or communities meet in war the members of one class, however widely separated by distance of space or time, will not injure or fight with each other. Each class has its characteristic features, and is associated with adverbs and propositions of—(1) an upper class of chiefs, from among whom the head (tamol or iros) is chosen; (2) a lower but still noble class; and (3) common people, mostly without rights of property. These last are only allowed one wife. Here and there are traces, as in Tonga, of a spiritual sovereign, the descendants probably of a conquered dynasty. Succession is through the female side, which assures to women a certain position, and leads besides to some curious results (see paper by J. S. Kubary in Das Ausland, 1880, No. 27). The upper class are the keepers of traditions, boat-builders, leaders of expeditions; tattooing is generally done by them, the amount incurred to a man according to his rank. There are still definite religious associations. Both sexes are tattooed.

The Marshall Islanders are the boldest and most skillful navigators in the Pacific. The voyages of the long months of sailing with outwinder, well-provisioned, and depending on the skies for fresh water, help to show how the Pacific was colonized. They have a sort of chart, medo, of small sticks tied together, representing the positions of islands and the directions of the winds and currents. A two-edged weapon, of which the blade is of sharks' teeth and a defensive armour of braided sennit, are also peculiar to the islands; a large axe, made of the shell of the Tridacna gigas (the largest bivalve known), was formerly used in the Carolines, probably by the old builder race.

The dialects of Micronesia, though grammatically alike, differ widely in their vocabulary. The chief names of the Polynesians and Malay affinities, and peculiarities such as the use of suffixes and inseparable pronouns and, as in Tagalog, of the infix to denote changes in the verb; in the west groups there is a tendency to closed syllables and double consonants, as contrasts to the palatals ch, j, sh, the dental th, and s (the last perhaps only in foreign words), which is alien to the Polynesians. These letters are wanting in the Gilbert language, which differs considerably from all the others. It adapted a large number of felspar words from Hawaiian and has borrowed from New Guinea. Most words take the accent on the penult. In some of the dialects there appears to be no true article, but in the Gilbert Islands the Polynesian is used for both definite and indefinite articles. Generally speaking, it is used only when the noun is either gathered from the is sexually one, or is not the root, and the noun is either gathered from the from the west and also from the east. Those who came from the east are expressly said to be from Samoa. Those who came from the west were more numerous than those from the east. There are also traditions of the arrival of other strangers at some of the islands, e.g. the Carolines and the Gilberts. In the Marshalls and Carolines, whose language was 

**MICRONUCLEUS—MICROPEGMATITE**

With regard to their racial habits, the Micronesians are said to be "graphic," because the canoes of the Gilberts, of the Gilbert islands, and the outer islands, are all divided into triangular areas dotted over a felspathic background resembling certain primitive inscriptions. Microppegmatite differs from "graphic granite" only in being so much finer grained that its nature can only be detected with the microscope. The felspar of microppegmatite is usually orthoclase, but sometimes albite, oligoclase, or microcline. Occasionally it has the crystalline form, and then it has been proved that the quartz
MICROSCOPE

... may be so disposed that the two minerals have a definite relation between their crystallographic axes (parallel growth). The quartz typically occurs as angular patches; at other times it forms club-shaped, curved or veeformed threads (vermicular micropegmatite, myrmekite), and then some authors consider that the felspar has been corroded and the quartz fills up the spaces thus produced (quartz de corrosion of French petrographers). Micropegmatite is often so fine grained that even in the thinnest sections and with high powers it cannot be resolved into its components. This fine micropegmatite resembles threads, having a divergent arrangement. In some rocks the whole ground mass consists of such spherical growths of fibrous micropegmatite (see Quartz—Porphyry); in their centres there is often a quartz or felspar crystal; the outer boundaries of the spherulites are not usually circular but irregular owing to the interlocking of adjacent spherulites at their margins ("granophyric structure"). Micrographic structures may occur in other minerals, e.g. quartz and garnet, cordierite, epidote or hornblende, augite and felspar, but are less common, and the name micropegmatite is usually reserved for aggregates of quartz and felspar.

In rocks where micropegmatite frequently occurs (e.g. granite, porphyry and granophyre, quartz-diorite) it is usually the last mineral to crystallize, and many of the minerals in the mother rock have been afterwards altered or separated, and over after the other minerals had separated out in more or less perfect crystals. Hence it has no definite form of its own, but fills up the irregular interspaces between the earlier crystallizations. For this reason it has been compared to a eutectic mixture, and often has been estimated to be the mixture of quartz and felspar which has the lowest fusion point. Eutectics are common in alloys and often have a very perfect micrographic structure. The eutectic mixture of quartz and orthoclase has been estimated to contain 70-75% of the latter. This theory, however, is not without its difficulties; analyses of micropegmatite prove that its composition is by no means constant (this may perhaps be due to small admixtures of sodas and limes of felspars); and experimental researches on the fusion points of mixtures of quartz and felspar have not yet shown that there is a definite mixture which melts at a lower temperature than any other mixture of quartz and felspar. Perhaps such a eutectic product, as a eutectic should be, but may occur as well-shaped eutectoids lying in a felsitic or glassy matrix which solidifies at a still later time. Micrographic structures in the marginal parts of igneous rocks prove only that these minerals crystallized simultaneously.

(M. S. F.)

MICROSCOPE (Gr. μικρός, small, σκοτεινός, to view), an optical instrument for examining small objects or details of such objects; it acts by making the angles of vision under which the images appear greater than when the objects themselves are viewed by the naked eye.

Microscopes are distinguished as simple and compound. A simple microscope consists of a single positive lens, or of a lens combination acting as a single lens, placed between the eye and the object so that it presents a virtual and enlarged image. The compound microscope generally consists of two positive lens systems, so arranged that the system nearer the object (termed the objective) projects a real enlarged image, which occupies the same place relatively to the second system (the eyepiece or ocular) as does the real object in the simple microscope. An image is therefore projected by the ocular from the real magnified image produced by the objective with increased magnification.

History of the Simple Microscope.—Any solid or liquid transparent medium of lenticular form, having either one convex and one flat surface or two convex surfaces whose axes are coincident, may serve as a "magnifier," the essential condition being that it shall refract the rays which pass through it so as to cause widely diverging rays to become either parallel or but slightly divergent. Thus if a minute object be placed on a slip of glass, and another similar object be placed upon it, the drop will act as a magnifier in virtue of the concavity of its upper surface, so that when the eye is brought sufficiently near it (the glass being held horizontally) the object will be seen magnified. Again if a small hole be made in a thin plate of metal, and a minute drop of water be inserted in it, this drop, having two convex surfaces, will serve as a still more powerful magnifier. There is reason to believe that the magnifying power of transparent media with convex surfaces was very early known. A convex lens of rock-crystal was found by Layard among the ruins of the-temple of Ninurta; Seneca describes hollow spheres of glass filled with water as being commonly used as magnifiers.

The perfect gem-cutting of the ancients could not have been attained without the use of magnifiers; and doubtless the Greeks who executed these wonderful works also made them. Convex glass lenses were first generally used to assist ordinary vision as "spectacles"; and not only were spectacle-makers the first to produce glass magnifiers (or simple microscopes), but by them also the telescope and the compound microscope were first invented. During the Thirty Years' War the simple microscope was widely known. Descartes (Dioptrique, 1637) describes microscopes wherein a concave mirror, with its concavity towards the object, is used, in conjunction with a lens, for illuminating the object, which is mounted on a point fixing it at the focus of the mirror. Antony van Leeuwenhoek appears to be the first to succeed in grinding and polishing lenses of such short focus and perfect figure as to render the simple microscope a better instrument for most purposes than any compound microscope then constructed. At that time the "compass" microscope was in use. One leg of a compass carried the object, and the other the lens, the distance between the two being regulated by a screw. Stands were also in use, permitting the manipulation of the object by hand. Robert Hooke shaped the minutest of the lenses with which he made many of the discoveries recorded in Micrographia. From small glass globules made by fusing the ends of threads of spun glass; and the same method was employed by the Italian Father Di Torre. Early opticians and microscopists gave their chief attention to the improvement of the simple microscope, the principle of which we now explain.

Simple Microscope

Position and Size of the Image.—A person with normal vision can see objects distinctly at a distance varying from ten inches to a very great distance. Objects at different distances, however, appear different in size. This apparent distance of the object varies with its size, and this is effected by the power of accommodation of the eye, which can so alter the focal length of its crystalline lens that images of objects at different distances can be produced rapidly and distinctly one after another upon the retina.

The angle under which the object appears depends upon the distance and size of the object, or, in other words, the size of the image the eye receives is determined by the distance and the dimensions of the object. The ratio between the real size of the object y (fig. 1) and the distance l, which is equal to the tangent of the visual angle w, is termed the "apparent size" of the object. From the figure, which represents vision with a motionless eye, it is seen that the apparent size increases as the object under observation is approached. The greater the visual angle, the more distinctly are the details of the object perceived. On the other hand, as the observer recedes from the object, the apparent size, and also the image on the retina diminishes; details become more and more confused, and gradually, after a while, disappear altogether, and ultimately the external configuration of the object as a whole is no longer recognizable. This case arises when the visual angle, under which the object appears, is approximately a minute of arc; it is due to the physiological construction of the retina, for the ends of nerve fibres, which receive the impression of light, have themselves a definite size. The lower limit of the resolving power of the eye is reached when the distance is approximately 34:48 times the size of the object. If the object be represented by two separate points, these points would appear distinct to the normal eye only so long as the distance between them is at the most equal to the diameter of their distance from the eye. When the latter distance is increased still further, the two appear as one. Therefore when it is desired to distinctly recognize exceedingly small objects or details of such, they are brought as near as possible to the eye. The eye is aided in bringing its focal length to the smallest possible amount, and when this strain is long continued it may cause pain. When the shortest distance obtained by the highest strain of accommodation is insufficient to recognize small objects, distinct vision is possible at even a shorter distance by placing a very small diaphragm.
between the eye and the object, the pencils of rays Proceeding from different object-points, which otherwise are limited by the pupils of the eye, being thus restricted by the diaphragm. The object is then projected with such acute pencils on the plane focused for, in this case on the plane on which the eye can just accommodate itself, that the image of confusion arising there is still so small that it is below the limit of angular visual distinctness and on that account appears as a sharp point. However, the loss of light in this process is great, and it may be said that only most intensely illuminated objects can be investigated.

A naked short-sighted eye, which would be corrected for distant objects by a spectacle glass of -10 dipters, may approach the object up to about 4 in. and have a sharp image upon the retina without any strain whatever. For the observation of small objects, a myopic eye is consequently superior to a normal eye; and the confused image of the retina may be extended by the object lenses so that the details are no longer recognizable by the unaided eye, the magnifying glass or the simple microscope is necessary. As a rule large magnification is not demanded from the former, but a larger field of view, whilst the simple microscope should ensure powerful magnification even when the field is small. The simple microscope enlarges the angle of vision, and does not tire the eye when it is arranged so that the image lies in the farthest limit of distinct vision (the fumction remotum). A normal eye would then see an image formed by the magnifying glass most conveniently when it is produced at a great distance, i.e., when the object is in its front focal plane. If y (fig. 2) be the object the image appears to a normal eye situated behind the system L with passive accommodation at a very great distance, D.

The length of the partial of the simple microscope, the visual angle w' is given by

\[ \tan \frac{w}{y} = \frac{1}{f} = \frac{v}{F} \]

in which f' = H' F', is the image-side focal length (see LESS). Since the lens is bounded by air, the image- and object-side focal lengths f and f are equal. The value 1/f or V in (1) is termed the power of the lens. In most cases the number of diameters of the simple microscope is required; i.e., the ratio between the apparent sizes of the object when observed through the microscope and when viewed by the naked eye. When a person of normal vision views a small object, he brings it to the distance of distinct vision, which would average about 10 in. The apparent size is then (fig. 1) tan w = y = f, where l = 10 in., whilst the apparent size of the object viewed through the magnifying glass would result from the formula (1) tan w = y'. Consequently the number of diameters will be

\[ N = \frac{w}{w'} = \frac{y}{y'} = \frac{1}{f} \frac{1}{f'} = \frac{V}{V'} \]

(2)

it is thus equal to the magnifying power multiplied by the distance of observation X the number of times that the real length is contained in 10 in.

Since this value for the distance of distinct vision is only conventional, it is understood that the capacity of the simple microscope given in (2) holds good only for eyes accustomed to examine small objects to 10 in. away; and observation through the magnifying glass must be undertaken by the normal eye with passive accommodation. A lens of 1 in. focal length must be spoken of, according to this notation, as W X 10 to lens, and a lens of 1/3 in. focal length as a X 100 lens. Obviously the position of a normal eye free from accommodation is immaterial for determining the magnification. A X to lens notation, however, does not guarantee to a myopic eye of -10 D by a lens of 1 in. focus. Since this short-sighted observer can view the object with the naked eye with no inconvenience whatever when he focuses it on the retina, the apparent size is tan w = 4; and to secure convenient vision through the lens the short-sighted person would bring the object to a virtual, magnified image would be projected in his pinacite remontum. In addition it will be supposed that the centre of the pupil of the observer coincides with the back focal point of the system. The apparent size of the object seen through the lens is then tan w = y'. The magnification, resulting from the simple microscope of the above, is here N = tan w/tan w' = y'/y = f/f' = 4. Thus, while a lens of 1 in. focal length assures to the short-sighted individual a X 10 magnification, it affords to the short-sighted individual only a X 4. On the other hand, it is easy of greater interest to the hypermetropic than to the observer of normal sight. From this it appears that each observer obtains certain advantages from one and the same simple microscope, and also the individual observer can obtain different magnifications by either using different accommodations, or by viewing in passive accommodation.

Regulation of the Rays.—In using optical instruments the eye is inevitably moved just in free vision that is to say, the attention is fixed upon the individual parts of the image one after another, the eye being turned in its cavity. In this case the eye is always directed so that the part of the image which is wished to be viewed exactly falls upon the most sensitive portion of the retina, viz., the macula lutea (yellow spot). Corresponding to the size of the yellow spot only a small fraction of the image appears particularly distinctly. The other objects which are recognized on the retina on the regions surrounding the yellow spot will also be perceived, but with reduced definition. These external and less sensitive parts of the retina, therefore, merely give information as to the general arrangement of the objects and to a certain extent act as guide-post in order to show quickly and conveniently, although not distinctly, the places in the image which should claim special attention. Vision with magnifying eyes or indirect vision gives a general view over the whole object with particular definition of a small central portion. Vision with a movable eye, or "direct vision," gives exact information as to the parts of the object one after another.

The simple microscope permits such vision. If the instrument has a sensible lens diameter, and is arranged so that the centre of rotation of the eye can coincide with the intersection of the principal rays, it can then form with the eye a converted system. Such lenses are termed "lenses for direct vision." By moving the eye about its centre of rotation M the whole field can be examined. The position of the mount of the lens serves as the diaphragm of the field of view. The selection of the rays emerging from the lens and actually employed in forming the image is undertaken by the pupil of the eye which, in this case, is consequently the exit pupil of the instrument. In fig. 3 P"P' designates the exit pupil of the lens, and the image of P"P', i.e., P", which is formed by the lens, limits the aperture of the pencils of rays on the object-side; consequently it is the entrance pupil of the instrument. Since the exit pupil moves in observing the whole field, the entrance pupil also moves. The principal rays, which on the object-side connect the object-points with the centre of the entrance pupil, intersect the axis on the image-side at the centre of rotation M of the eye. M being the intersection of the principal rays.

So long as the exit pupil is completely filled the brightness of the image will be approximately equal to that of free vision. If, however, we fix the points lying towards the margin of the field of view, the diaphragm gradually cuts out more and more of the rays which were necessary to fill the pupil, and in consequence the brightness gradually falls off to zero. This vignetting can be observed on all lenses.

In most cases, and also in corrected systems, the intersection of the principal rays is no longer available for the centre of rotation of the eye, and this kind of observation is impossible. In some instruments observation of the whole available field is only possible when the head and eye are moved at the same time, the lens retaining its position. DR M. von Rohr terms this kind of vision "peep-hole observation." It has mainly to be considered in connexion with powerful magnifying glasses. In most cases a diaphragm regulates the rays. Fig. 4 shows the position of the diaphragm to be considered in this kind of observation. PP' is the entrance pupil, P"P' the exit pupil, and the diaphragm. The intersection of the principal rays in this case lies in the middle of the entrance pupil or of the exit pupil. By head and eye motion the various parts of the whole field can be viewed one after another. The distance of the eye from the lens is here immaterial. In this case also the illumination must fall to zero by the vignetting of the pencils coming from objects at the margin of the field of view. C and D are the outermost rays which can pass through the instrument. Magnifying glasses are often used for viewing three-dimensional objects. Only points lying on the plane focused for can be sharply reproduced in the retina, which acts as object-plane to the retina.

1 See also LESS.
All points lying out of this plane are reproduced as circles of confusion. The central projection, of which the centre is the middle point of the entrance pupil on the plane focused for, will show in weaker systems, if those very closely cropped down, a finite intensity of definition; that is to say, the totality of points, which lie out of the plane focused for, and which are projected with circles of confusion so small that they appear to be sharp points, is a measure of the perfect definition, and the depth of definition of the lens. With increasing magnification the depth of definition diminishes, because the circles of confusion are greater in consequence. Very powerful simple microscopes have hardly any depth of definition so that in fact only points lying in one plane can be seen sharply with one focusing.

The diminution. So long as the pupil of the observer alone underlies the regulation of the rays there is no perceptible diminution of illumination in comparison with the naked eye vision. The losses of light which occur in this case are due to reflection, which takes place in the passage of the light through the glass surfaces. In a lens with two bounding surfaces in air there is a loss of about 9%; and in a lens system consisting of two separated lenses, i.e. with four surfaces in air, about 17%. Losses due to absorption are almost zero when the lenses are very thin, as with lenses of small diameter. A very marked diminution in illumination occurs, however, when the exit pupil of the instrument is smaller than the pupil of the eye, or when instruments are arranged so as to be required to intensely illuminate the object.

Forms of the Simple Microscope.—If the ordinary convex lens be employed as magnifying glass, great aberrations occur even in medium magnifications. These are: (1) chromatic aberration, (2) spherical aberration and (3) astigmatism (see Aberration). When the pupil regulating the aperture is the same case are due to reflection, which takes place in the passage of the light through the glass surfaces. In a lens with two bounding surfaces in air there is a loss of about 9%; and in a lens system consisting of two separated lenses, i.e. with four surfaces in air, about 17%. Losses due to absorption are almost zero when the lenses are very thin, as with lenses of small diameter. A very marked diminution in illumination occurs, however, when the exit pupil of the instrument is smaller than the pupil of the eye, or when instruments are arranged so as to be required to intensely illuminate the object.

The diminution. So long as the pupil of the observer alone underlies the regulation of the rays there is no perceptible diminution of illumination in comparison with the naked eye vision. The losses of light which occur in this case are due to reflection, which takes place in the passage of the light through the glass surfaces. In a lens with two bounding surfaces in air there is a loss of about 9%; and in a lens system consisting of two separated lenses, i.e. with four surfaces in air, about 17%. the stage, a black or white plate, forming a dark or light background, can be swung underneath the specimen.

In the field microscope the arrangement of the space of small objects is desired a stereoscopic lens can be used. In most cases refracting and reflecting systems are arranged so that the natural interpupillary distance has been preserved. Some lenses are more powerful systems, for the main idea is the recognition of the depth of objects, so that only systems having a sufficient depth of definition can be utilized. Very often such stereoscopic lenses, owing to faulty construction or the idea of using them in the simple type, has proved erroneous; and the principal attention of modern opticians has been directed to the compound instrument. Although we now know how the errors of lenses may be corrected, and how the simple microscope may be improved, this instrument remains with relatively feeble magnification, and to obtain stronger magnifications the compound form is necessary.

By combining two lenses or lens systems separated by a definite interval, the focal length obtained having a focal length contained by less than the focal lengths of the separate systems. If and are the focal lengths of the combination, and the focal lengths of the two components, and the distance between the inner focal point of the compound lens and the outer focal point of the objective, the focal length of the compound is also equal to the distance . The second focal point of the combined system, being situated before the front focus of the objective, the magnification due to the simple system makes the object distance greater than that obtained with a simple microscope of equal magnification. Moreover, this distance is twice as long as the focal length of the object-side lens, and the ratio of the object-side to the image-side focal lengths is substantially increased in the compound microscope by the stand: the inconveniences, and in certain circumstances also the dangers, to the eye when using a compound microscope, for example by warming the objective, are also avoided. The conversion from the compound to the simple microscope, as pointed out by obtaining by changing the eyepiece or the objective is also a special advantage of the compound form.

In the commonest compound microscopes, which consist of two positive systems, a real magnified image is produced by the objective. This permits research which are impossible with the simple microscope. For example, the real image may be recorded on a photographic plate; it may be measured; it can be physically altered by polarization, by spectrum analysis of the light employed by absorbing layers, &c. The greatest advantage of the compound microscope is that it represents a larger area, and this much more completely than is possible in the simple form. According to the law of optics, it is only possible either to portray a small object near one of the focus of the system with wide pencils, or to produce an image from a region opposite to the other focus, by the use of a monochromatic pencil. The simple microscope is subject to either limitation. As we shall see later, one of the principal functions of the microscope objective is the representation with wide pencils. In that case, however, in the compound microscope a small object may always be represented by means of wider pencils, one of the foci of the objective (not of the collective system) being near it. For the eyepiece the other rule holds: the object is represented by narrow pencils, and it is hence possible to subject the relatively great object, viz. the magnified real image, to a further representation.

**History of the Compound Microscope.**—The arrangement of two lenses so that small objects can be seen magnified followed soon after the discovery of the telescope. The first compound microscope (discovered probably by the Middelburg lens-grinders, Johann and Zacharias Jansen about 1600) was a combination of a strong biconvex with a still stronger biconcave lens; it had, thus, as well as the first telescope, a negative eyepiece. In 1666 Fontana described a microscope which had a positive eyepiece. The development of the compound microscope essentially depends on the improvement of the objective; but no distinct improvement was made in its construction in the two centuries following the discovery. In 1668 the Italian Divini employed several doublets, i.e. pairs of plano-convex lenses, and his example was followed by Griendl von Ach. But even with such magnification as these instruments permitted many faults were apparent. A microscope, using concave mirrors, was proposed in 1672 by Sir Isaac Newton; and he was succeeded by Barker, R. Smith, B. Martin, D. Brewster, and, above all, Amici. More recently these catadioptric microscopes were disregarded because they yielded unfavourable results. From 1830 onwards many improvements were made in the microscope objective; these may be best followed from a discussion of the faults of the image.

**Position and Size of Image.**—In most microscopical observations the object is mounted on a plane glass plate or slide about 0·06 in. thick, embedded in a liquid such as water, glycerine or Canada balsam, and covered with a plane glass plate of about 0·006 in. thick called the cover-slip. If we consider the production of the image of an object by means of a compound microscope shown in fig. 13, the objective forms a real magnified image . The object , the focal distance of the image, and the image-side focal length , then the magnification is

\[
M = \frac{y'}{y} = \frac{f'_{1}f}{f_{0}}
\]

(3)

The distance is called the " optical tube length." Weak and strong microscope objectives act differently. Weak systems act like photographic objectives. In this case the optical tube length may be altered within fixed limits without spoiling the image; at the same time the objective magnification is also altered. This can be done by mounting the objective and eyepiece on two telescoping tubes, so that by drawing apart or pushing in the object-side length is increased or diminished at will. For strong objectives there is, however, only one optical tube length in which it is possible to obtain a good image by means of wide pencils, any alteration of the tube length involving a considerable spoiling of the image. This limitation is examined below.

When forming an image by a microscope objective it often happens that the transmitted rays from one system have different optical properties. A series of objectives with short focal lengths are always chosen so as to permit the placing of a liquid between the cover-slip and the front lens of the objective; such lenses are known as immersion objectives. The liquid is not bounded on both sides by air but is called " dry systems." The immersion liquids in common use are water, glycerine, cedar-wood oil, mononaphthalene, &c. Immersion systems in which the embedding liquid, cover-slip, immersion-lens and front lens have equal refractive indices are called "homogeneous immersion systems." In immersion systems the object-side focal length is greater than the image-side focal length. Nothing is altered as to objective magnification, however, if the first surface is plane, and the employment of the immersion means that the value of is unaltered.

If we assume that a normal eye observes the image , the eyepiece must project a distant image from the real image produced by the objective. This image is imaged by the eyepiece with the eyepiece , and the exit pupil of the eyepiece , the eyepiece must project a distant image from the real image produced by the objective. This image is imaged by the eyepiece with the eyepiece , and the exit pupil of the eyepiece . The image viewed through the eyepiece appears then to observer under the angle , and as with the single microscope

\[
\tan \theta = \frac{D}{2f_{1}}
\]

(4)

where is the image-side focal length of the eyepiece.
To obtain the magnification of the complete microscope we must combine the objective magnification $M$ with the action of the eye-piece. If we replace $y'$ in equation (4) by the value given by (3), we obtain

$$\tan w' = y'(1 + f' f'_{0}) = V/I.$$  

(5)

The magnification of the complete microscope. The magnification therefore equals the power of the joint system.

The magnification is also expressed as the ratio of the apparent size of the object observed through the microscope to the apparent size of the object seen with the naked eye. As the converging distance for clear vision with naked eye is to $w$, it results from (4) that the apparent size is $w = y'. \theta$.

If this value of $y'$ is inserted in equation (5), we obtain the magnification number of the compound microscope:

$$N = \tan w / \tan w = \frac{1}{1 + f' f'_{0}} = V/I.$$  

(6)

The magnification number increases then with the optical tube-length and with the diminution of the focal lengths of objective and eye-piece, directly.

The simplest microscope which produces an upright image has a positive objective and one negative lens as eye-piece. As shown in fig. 14, the real image formed by the objective must fall on the object-side focal plane of the eye-piece $F$, where a normal eye without accommodation can observe it.

But as the object-side focus $F$ lies behind the eye-piece, the real image is not produced, but the converging pencils from the objective may be changed by the eye-piece into parallaxes; and the point $O_1$ in the top of the object $y$ appears at the top to the eye, and the image is upright.

The erection of inverted images by prisms, which was applied to the simple telescope by Porro, and to the binocular (fig. 13), by Blucher was employed by K. Bratuscheck in the Greenough double microscope; these inverting prisms adapt a convenient instrument to the interpellary distance of the observer. Double microscopes, which produce a correct impression of the solidity of the object, must project upright images. The terrestrial eye-piece (see TELESCOPE), which likewise ensures an upright image, but which gives an inconvenient lengthening, has also been employed in the binocular microscope.

Regulation of the Rays.—Weak and medium microscope objectives work like photographic objectives in episcopic or diascopic projection; in the microscopes, however, the projected image is not intercepted on a screen, but a real image in air is formed. This must lie in the front focal plane of the eye-piece if we retain the supposition that it is to be viewed by a normal eye with passive accommodation. The plane of the object conjugate to the focal plane of the eye-piece is the plane focused for; and all points in it are sharply portrayed (a perfect objective image) by the objective. Object points lying at the focal plane of the objective, on the other hand, are projected as circles of confusion on the plane focused for, the centre of each entrance pupil being the centre of projection and the circles of confusion constituting, with the points of the focal plane, the object-side image plane. These pencils used in the representations are of wide aperture on the object-side, only such points as are proportionately very near the object can produce such small dispersion circles on the plane focused for, that they, so far as the objective and eye-piece magnify the image, permit, appear as points to the eye. It follows that the depth of definition of the microscope is in general very trivial. As it is entirely a function of the aperture and the magnification, it can be increased by diminishing the entrance pupil, the magnification remaining unchanged. A diminution of the aperture, however, would injure a very much more important property, with the resolving power (see below).

With powerful systems, object-points lying quite near the plane focused for would be represented by such large dispersion circles that practically only the points lying in one plane, and not in another, are seen. It would therefore be expected that the object-points lying in other planes can be observed.

The position of the diaphragm limiting the pencils proceeding from the object-points is not constant in the compound microscope. In all microscopes the rays are limited, not in the eye-piece, but in the objective, or before the objective when using a condenser. If the pencils are limited in the objective, the restriction of the pencil proceeding from the object-point is effected by the front lens, which is the boundary of a lens lying behind, by a real diaphragm placed between or behind the objective, or by a diaphragm-image.

The centre of the entrance pupil is the point of intersection of the principal rays, and it is therefore determinant for the perspective representation on the plane focused for. In fig. 15 the centre of the entrance pupil lies behind the focal plane, and consequently nearer objects appear larger, and farther objects smaller ("entocentric transmission," see below). If a diaphragm lying in the back focal plane of the objective forms the exit pupil for the objective, as in figs. 13 and 14, so that its image, the entrance pupil, lies at infinity, then all the principal rays in the object-space are parallel to the axis, and we have on the object-side "telecentric" transmission. The size of the image on the focal plane is always equal to its actual size, and is independent of the distance of the object from the plane focused for. This representation acquires a special importance if the object be microscopically measured, for an inaccuracy in focusing does not involve an alteration of the size of the image. To ensure the telecentric transmission, the diaphragm in the back focus of the objective may be replaced by a diaphragm in the front focal plane of the condenser, supposing that uniformly illuminated objects are being dealt with; for in this case all the principal rays in the object-space are transmitted parallel to the axis.

With uniformly illuminated objects it may happen that the pencil in the objective may be limited before the objective, the object, either through the size of the light employed or through a diaphragm connected with the illuminating system. In fig. 16

**Fig. 15.** — Entocentric transmission through a microscope objective.

$E =$ plane focused for; $O_1^*, O_2^*$ = projections of $O_1, O_2$ on $E$; $Z =$ centre of projection; $P = $ virtual image of real diaphragm $P^*$, with regard to the preceding part of the objective is the entrance pupil.

**Fig. 16.** — Hypercentric transmission in a microscope objective.

$E, O^*_1, O^*_2$ and $Z$ as in fig. 15. $P^*_I$ is the entrance pupil.

The intersection of the principal rays lies in front of the object, and consequently objects in front of the plane focused for will be projected on $E$ magnified and the objects lying behind it diminished ("hypercentric" transmission). It produces a perspective representation entirely opposed to ordinary vision. As objects lying farther from $E$ are hypercentric transmitted than those lying farther from $E$, we conceive a false impression of the spatial arrangement of the object.

Whether the entrance pupil be before or behind the object, in general it is impossible to limit the rays traversing the object, so that the principal rays will have in the object space only trifling inclinations towards one another or are strictly parallel. This is specially important, for otherwise pencils from points placed somewhat laterally to this points arrive at each other.

We see from fig. 13 that the objective's exit pupil $P^*_I$ is portrayed by the positive eye-piece, the image $P^*_I$ limits the pencils...
proceeding from the eyepiece. This image \(P'P''\) is then the exit pupil of the combined system, and consequently the image of the entrance pupil of the combined system. As the exit pupil \(P'T\) for the objective lies before the front focus of the eyepiece, generally at some distance and near the objective, the eyepiece projects a real image from it behind its image-side focus, so that if this point is accessible it is the exit pupil of the eyepiece. If the object-space of the objective has telecentric transmission, the exit pupil must coincide with the back focal plane of the combined system, and it always lies behind the image-side focus of the eyepiece. The exit pupil, often called Ramsden's circle, is thus inaccessible to the user, who by head- and eye-movements may survey the whole field.

We can now understand the ray transmission in the compound microscope, shown in Fig. 13. Points of a small object (compared with the squares of the principal semi-diagonals) are rendered visible. The diaphragm limiting them, i.e. the entrance pupil, is placed so that the principal rays are either parallel or slightly inclined. The pencils producing the real image are very much more acute than their inclination is the smaller the stronger the magnification. The eyepiece, which by means of narrow pencils represents the relatively large real image at infinity, transmits from all points of this real image parallel pencils, whereby the inclination of the principal rays becomes further increased. The point of intersection, i.e. the centre of the exit pupil, is accessible to the eye of the observer. In the case of the negative eyepiece, on the other hand, and the divergence of the principal rays through the eyepiece is also further augmented, but their point of intersection is not accessible to the eye. This property shows the superiority of the collective eyepiece over the dispersive.

The increase of the inclination of the principal rays, which arises with the microscope, influences the perception of the relief of the object. In entocentric transmission this phenomenon appears in general to the eye, and in the case of the compensating of perspective representations at a too short distance, the objects appearing flattened. Although in the case of the spatial comprehension of a perspective representation experience plays a large part, in observing through a microscope it does not count, or only a little, for the object is presumably quite unknown. In telecentric and hypercentric transmission we obtain a false conception of the spatial arrangement of the objects, on the other hand, and in these cases one focusses only on the different details, and so obtains an approximate idea of their spatial arrangement.

While the limiting of the pencil is almost always effected by the object, the limits of the field of view is effected by the eyepiece, and indeed it is carried out by a real diaphragm DD arranged in the plane of the real image \(O'V'\) (Fig. 13) projected from the objective. This is done to prevent the transmission of rays diffracted by the objective in the surface conjugate to the plane focused for, and the exit window is the image projected by the eyepiece; this happens with the image of the object lying at infinity. The result must be that the field of view will be always limited. In the case of the dispersive eyepiece, on the contrary, no sharply limited field can arise, but vignetting must occur.

Illumination.—The dependence of the clearness of the image on the aperture of the system, i.e. on the angular aperture of the image-producing pencil, holds for all instruments.

The brightnesses of image points in a median section of the pencil are always proportional to the cosine of the angle of incidence of the ray at the aperture, which is completely united. This is valid so long as the pencil is in air; but if, on the other hand, the pencil passes from air through a plane surface into an optically denser medium, e.g. water or glass, the pencil becomes more acute and the aperture smaller. But since no rays are lost in this transmission (apart from the slight loss due to reflection) the brightness of the image point in the water is as large as that in air, although the apertures have become less. Fig. 17 shows a pencil in air, A, dispersing in water, W, from the semi-aperture \(\mu_s\); or a pencil in water dispersing in air from the semi-aperture \(\mu_w\). If the value of the clearness in air be taken as \(\sin \mu_s\), then the law of refraction \(N\) : \(N\) is seen to the value of the clearness in water is \(N \sin \mu_w\). This rule is general. The value of the clearness of an image-point in a median section is the sine of the semi-aperture of the pencil multiplied with the refractive index of the medium.

The best illustration of this principle is the immersion experiment. A view taken under water from the point O (Fig. 18) sees not only the whole horizon, but also a part of the bed of the sea. The whole field of view in air of 180° is compressed to one of 97.5° in water. The rays from O which have a greater inclination to the vertical than 48.75° cannot come out into the air, but are totally reflected. If pencils proceed from media of high optical density to media of low density, and have a semi-aperture greater than the critical semi-aperture, the entire ray system is reflected. The immersion can be employed, hence front lenses have small radii of curvature in order to permit the wide pencils to reach the air (see Fig. 19, in which the preparation, O the object-point in it, D the cover slip, I the immersion liquid, in the objective, and Fig. 18).

The function \(\sin \mu = A\), for the microscope, has been called by Abbé the numerical aperture. In dry-systems only the sine of the objective is concerned; in immersion-systems it is the product of the refractive index of the immersion-liquid and the sine of the object-side semi-aperture. In the case of the brightness of large objects obviously the whole pencil is involved, and hence the clearness of the objective is limited. The numerical aperture of a pencil proceeding from an object point cannot exceed 90°, the numerical aperture of a dry-system cannot be greater than 1. Usually immersion systems permit the numerical aperture almost to amount to the refractive index for \(\lambda = 5892\AA\).

Dry systems of 0.98 numerical aperture, water immersion (\(n=1.53\)) from \(A=1.25\), off immersion (\(n=1.51\)) from \(A=1.40\), and even bромonaphthalene immersions (\(n=1.65\)) from \(A=1.60\), are available. In immersion-systems of such considerable aperture no medium of smaller refractive index than the immersion liquid may be placed between the surface of the front lens and the object, as otherwise total reflection would occur. This is especially important in the case of the Fraunhofer phenomenon, because if the embedding and immersing liquids must have equal refractive indexes, one must use bромonaphthalene for embedding; but this substance destroys organic preparations, so that one can employ this immersion-system only for examining inorganic materials, e.g. fine diatoms.

In immersion-systems a very much greater aggregate of rays is represented on the image than in the case of the dry system. In addition to a considerable increase in brightness the losses due to reflection are avoided; losses which arise in passing to the back surface of the coverslip and to the front surface of the front lens.

The PHYSICAL THEORY

In order to fully understand the representation in the microscope, the process must be investigated for the wave theory, especially in considering the representation of objects or object details having nearly the size of a wave-length. The rectilinear rays, which we have considered above, having no real existence, are nothing but the paths in which the light waves are transmitted. According to Huygens' principle (see DIFFRACTION) each aether particle, set vibrating by an incident wave, can itself act as a new centre of excitement, emitting a spherical wave; and similarly each particle on this wave itself produces wave systems. All systems which are emitted from a single source can by a suitable optical device be directed so that they simultaneously influence one and the same aether particle. According to the phase of the vibrations at the same point, the particle is either strengthened or weakened by their action, and there arises greater clearness or obscurity. This phenomenon is called interference (q.v.). E. Abbé applied the Fraunhofer diffraction phenomena to the explanation of the representation in the microscope of uniformly illuminated objects.

If a grating is placed as object before the microscope objective, Abbé showed that in the image there is an intermittent clear and dark banding only, if at least two consecutive diffraction spectra enter into the objective and contribute towards the image. If the illuminating pencil is parallel to the axis of the microscope objective, the illumination is said to be direct. If in this case the aperture of the objective be so small within the diffraction limits that each other, that only one pencil parallel to the axis, i.e. the spectrum of zero order, can be admitted, no trace is generally found of the image of the grating. If, in addition to the principal maximum, the maximum of 1st order is admitted, the banding is distinctly seen, although the image does not yet accurately resemble the object. The resemblance is greater the more diffraction spectra enter into the objective. The banding can immediately deduce the limit to the diffraction constant \(\delta\), so that the banding by an objective of fixed numerical aperture can be perceived. The value \(n \sin \alpha\) equals the numerical aperture \(A\), where \(n\) is the refractive index of the immersion liquid, and \(\alpha\) is the semi-aperture on the object-side. For microscopy the Fraunhofer formula is best written \(\delta = A/\lambda\). This expresses \(\delta\) as the resolving power in angular measure. In all other cases the resolving power of the system is obtained when the rays are resolved, if two diffraction maxima can be passed through the objective, so that the character of the object is seen in the image, even if an exact resemblance has not yet been attained. The Fraunhofer diffraction phenomena, which take place in the
back focal plane of the objective, can be conveniently seen with the naked eye by removing the eyepiece and looking into the tube, or better by focusing a weak auxiliary microscope on the back focal plane of the objective. If one then holds the eye close to the case of a grating, telecentric transmission on the object-side, and in the front focal plane of the illuminating system a small circular aperture is arranged, thereby the help of the auxiliary microscope one sees the phenomenon of the back focal plane the round white image 0 (fig. 20) and to the right and left the diffraction spectra, the images of different colours partially overlapping. If a resolvable grating is considered, the distance between the orders of the appearance shown in fig. 21.

It is possible to almost double the resolving power, as in the case between spectral and real marks. To determine the utility of an objective for resolving fine details, one experiments with definite objects; in the auxiliary microscope employed simultaneously for examining its other properties. Most important are the fine structures of diatoms such as *Surirella gemma* and *Amphipleura pellicula* or artificial fine divisions, for such as, if single spectromicroscopic objectives can only be attempted when the different faults of the objective are known.

If microscopical preparations are observed by diffused daylight or by the moon or less white light of the usual artificial sources, then one finds that a negative objective of fixed numerical aperture will only represent details of a definite fineness. All smaller details are not portrayed. The Fraunhofer formula permits the determination of the most useful magnification of such an objective in order to utilize its full resolving power.

If no magnifying power is assumed for daylight observation, then according to Abbe (Journ. Roy. Soc., 1882, p. 463) we have the following formula for the limits of the magnification numbers, for various microscope objectives, \( \mu = 0.001 \) mm.

\[
A = \sin \theta - \frac{d}{\mu \cdot N_p \cdot N_o}
\]

\[
N_p = \left( \frac{0.01}{\theta} \right)^2 + 0.95
\]

\[
N_o = \frac{0.1}{d}
\]

From this it can be seen that, as a rule, slight magnifications suffice to bring all representable details into observation. The magnification is below the given numbers, the details can either not be seen at all, or only very indistinctly; if, on the contrary, the given magnification is increased, there will still be no more details visible. The table shows at the same time the great superiority of the objective for fine-meshed diffraction-spectra or for the double layer of the resolving power. With the best immersion-system, having a numerical aperture of 1.6, details of the size 0.17 \( \mu \) can be resolved, while the theoretical maximum of the resolving power is 0.167 \( \mu \), so that the theoretical resolving power is already attained in practice. Still smaller particles cannot be portrayed by using ordinary daylight.

In order to increase the resolving power, A. Köhler (Zeit. f. Mikr., 1904, 21, pp. 129, 273) suggested employing ultra-violet light, of a wave-length 275 \( \mu \); he thus increased the resolving power to about double that which is reached with day-light, of which the mean wave-length is 550 \( \mu \). Light of such short wave-length is, however, not visible, and therefore a photographic plate must be employed. Since glass does not transmit the ultra-violet light, quartz is used, but such lenses can only be spherical in correction and not chromatically correct. For this reason the objectives have been called monochromats, as they have only been corrected for light of one wave-length. Further, the different objectives, which are usually made of the same materials, are constructed to the same refractive index it is unnecessary to dye the preparations. Glycerin is commonly used as immersion fluid.

M. v. Rohr's monochromats are constructed with apertures up to 1.25. The smallest resolving detail with oblique light is the division as in a Néelot's grating. The examination that usually estimates the resolving power according to the aperture with ordinary day-light, Köhler introduced the "relative resolving power" for ultra-violet light. The power of the microscope is thus represented by the ratio of the useful aperture to the numerical aperture or

\[ \frac{275}{1.25} \]

Then the denominator of the fraction, the numerical aperture, must be correspondingly increased, in order to ascertain the real resolving power of the microscope. Köhler showed that in this way a monochromat for glycerin of a numerical aperture 1.25 gives a numerical aperture of 800.

If the magnification be greater than the resolving power demands, the observation is not only needless made more difficult, but the light that is diminished and the transparency of the objective is affected by the presence of a certain aperture the size of the exit pupil depends upon the magnification. The diameter of
the exit pupil of the microscope is about 0.04 in, with the magnification N, and about 0.02 in, with the magnification N. Moreover, with such exceptionally narrow pencil shadows are formed on the retina of the observer's eye, from the irregularities in the eye itself. These disturbances are called "entoptic phenomena." From the section Regulation of the Rays (above) it is seen that the resolving power is opposed to the depth of definition, which is measured by the reciprocal of the numerical aperture, t/A.

Dark-field Illumination.—It is sometimes desirable to make minute objects in a preparation specially visible. This can be done by cutting off the chief maximum and using only the diffracted spectra for producing the image.

At least two successive diffraction maxima must be admitted through the objective for there to be any image of the objects. With this device these particles appear bright against a dark background, and can be easily seen. The cutting off of the chief maximum can be effected by a suitable diaphragm in the back focal plane of the objective. But, owing to the various partial reflections which the illuminating cone of rays undergoes when traversing the surfaces of the lenses, a portion of the light comes again into the preparation, and into the eye of the observer, thus veiling the image. This defect can be avoided (after Abbe) if a small central portion of the back surface of the front lens be ground away and blackened; this portion should exactly catch the direct cone of rays, whilst the edges of the lens let the deflected cone of rays pass through (fig. 28).

![Image](https://via.placeholder.com/150)

**Fig. 28.**

The large loss of light, which is caused in dark-field illumination by the cutting off of the direct cone of rays, must be compensated by employing exceptionally strong sources. By dark-field illumination it is even possible to make such small details of objects perceptible as are below the limits of the resolving power. It is a similar phenomenon to that which arises when a ray of sunlight falls into a darkened room. The extremely small particles of dust (moles in a sunbeam) in the rays are made perceptible by the diffracted light, whilst by ordinary illumination they are invisible. The same observation can be made with the cone of rays of a reflector, and in the same way the fine rain-drops upon a dark background and the fixed stars in the sky become visible. It is not possible to recognize the exact form of the micro object, white objects become because their apparent size is much too small; only their presence is observable. In addition, the particles can only be recognized as separate objects if their apparent distance from one another is greater than the angular definition of sight.

**Ultramicroscopy.**—This method of illumination has been used by H. Siedentopf in his ultramicroscope. The image consists of a diffraction disk from whose form and size certain conclusions may be drawn as to the size and form of the object. It is impossible to get a representation as from an object. Very finely divided sub-microscopic particles in liquids or in transparent solids can be examined. And the method has proved exceptionally valuable in the investigation of colloidal solutions.

Siedentopf employed two illuminating arrangements. With the orthogonal arrangement for illuminating and observing the beam of light traverses an extremely fine slit through a well-corrected system, whose optic axis is perpendicular to the axis of the microscope; the system reduces the dimensions of the beam to about 2 μ, and the focal length of the objective or the observation it is the same as if a thin section of a thickness of 2 to 4 μ had been shown. In this optical way it is possible to show thin sections of living tissue, or objects whose dimensions are of the order of the wavelength of light. The phase-differential illumination, which certainly gives better results, is avoided in the coaxial apparatus. Care must here be taken, by using suitable dark-field screens, that no direct rays enter the observing system, but that only secondary spherical aberrations are allowed to enter. This is not possible with perfect gold points, and the images of the spherical aberrations are formed at the surface of the objective, which is necessarily for its resolving power, would be worthless. Owing to these aberrations, the fine structure, which in consequence of the large aperture could be resolved, could not be perceived. In the case of a sufficiently good and distinct image as the resolving power permits cannot be arrived at, until the elimination, or a sufficient diminution, of the spherical andchromatic aberrations has been brought about.

The objective and eyepiece may be made up of such different types that as a rule it is not possible to correct the aberrations of one system by those of the other. Such a compensation is only possible for one single defect, as we shall see later. The demands made upon the eyepiece, which has to represent a relatively large image, made by narrow cones of rays, are not very considerable. It is therefore not very difficult to produce a usable eyepiece. On the other hand, the correction of the objective presents many difficulties.

We will now examine the conditions which must be fulfilled by an objective, and then how far these conditions have been realized.

Consider the aberrations which may arise from the representation by a system of wide aperture with monochromatic light, i.e. the spherical aberrations. The rays emitted from an axial object-point are not combined into one image-point by an ordinary biconvex lens of finite aperture, but the rays from the convex surface of the lens, as usual, converge faster than the outer rays. The so-called "caustic" occupies a definite position in the image-space. The spherical aberrations, however, can be overcome, or at least so diminished that they are quite harmless, by forming appropriate combinations of lenses.

The aberration of rays in which the outer rays intersect the axis at a shorter distance than the central rays is known as "under-correction." The reverse is known as "over-correction." By selecting the radii of the surfaces and the kind of glass the under- or over-correction can be regulated. Thus it is possible to correct a system by combining a convex and a concave lens, if both aberrations of the same sign, but of opposite signs, are present. A spherical aberration of the crown lens must preponderate so that the resulting lens is of the same sign, but of a little less power. Correction of the spherical aberration in strong systems with very large aperture can not be brought about by combinations of a few lenses, but several partial systems are necessary. Further, under-corrected systems must be combined with over-corrected ones. Another way of correcting this system is to alter the distances. If, by these methods, a point in the optic axis has been freed from \( \text{ aberration, it does not follow that a point situated only a very small distance from the optic axis can also be represented without spherical aberration. The representation, free from aberration of a small surface-element, is only possible, as Abbe has shown, if the objective simultaneously fulfills the "sine-condition," i.e. if the ratio of the sine of the aperture \( u \) on the object-side to the sine of the corresponding angle \( u' \) on the image-side is equal to \( \frac{\sin u}{\sin u'} = C \), in which \( C \) is a constant. The sine-condition is in contrast to the tangent-condition, which must be regarded as a stereographic representation of the objective-image in the image-space (see Lippmann), but which would be impossible if \( \frac{\tan u}{\tan u'} = C \) must exist. These two conditions are only compatible when the representation is made with quite narrow pencils, and the aperture is so small that the sizes and tangents are of about the same value.

Very large apertures occur in strong microscope objectives, and hence the two conditions are not compatible. The sine-condition is fulfilled as far as the case of a single point is concerned, because it must be possible to represent a surface-element through the objective by wide cones of rays. The removal of the spherical aberration and the sine-condition can be accomplished for each object by using a wide-diaphragm objective with a wide aperture therefore can only represent, free from aberrations, one object-element situated on a definite spot on the axis. As any other object-element on this axis is situated, the spot representation is quite useless. Hence the importance of observing the length of the tube in strong systems. If the sine-condition is not fulfilled but the spherical aberrations in the
MICROSCOPE

The cones of rays issuing from a point situated only a little to the
side, which traverse different zones of the objective, have a
different magnification. The sine-condition can therefore also
be understood as follows: that the same four zones must have
the same magnification for the plane-element.

According to Abbé, a system can only be regarded as apochromatic if it is spherical corrected for not only one axial point, but when it also fulfills the sine-condition and thus magnifies equally in all zones a surface-element situated vertically on the axis at this point.

A second method of correcting the spherical aberration depends on the notion of applanatic points. If there are two transparent substances separated from one another by a spherical surface, then there are two points on the axis where they can be reproduced free from error by monochromatic light, and these are called "aplanatic points." The first is the centre of the sphere. All rays issuing from this point pass unrefracted through the dividing surface; its image-point coincides with it. Besides this there is a second point on the axis, from which all issuing rays are so refracted at the surface of the sphere that, after the refraction, they appear to originate from one point—the image-point (see fig. 30). With this, the object-point O, and consequently the image-point O' also, will be at a quite definite distance from the centre. If however the object-point does not lie in the medium with the index n, but before it, and the medium is, for example, like a front lens, still limited by a plane surface, just in front of which is the object-point, then in traversing the plane surface spherical aberrations of the under-corrected type again arise, and must be removed. By homogeneous immersion the object-point can readily be reduced to an aplanatic point. By experiment Abbé proved that old, good microscope objectives, which by mere testing had become so corrected that they produced usable images, were not only free from spherical aberrations, but also fulfilled the sine-condition, and were therefore really aplanatic systems.

The second aberration which must be removed from microscope objectives are the chromatic. To diminish these a collective lens of crown-glass is combined with a dispersing lens of flint; in such a system the red and the blue rays intersect at a point (see ABBERRATION). In systems employed for visual observation (to which class the microscope belongs) the red and blue rays, which include the physiologically most active part of the spectrum, are combined; but rays other than the two selected are not united in one point. The transverse sections of these cones of rays diverge more or less from the transverse section of the chosen blue and red cones, and produce a secondary spectrum in the image, and the images still appear to have a slightly coloured edge, mostly greenish-yellow or purple; in other words, a chromatic difference of secondary aberrations arises (see fig. 31). This refers to systems with small apertures, but still more so to systems with large ones; chromatic aberrations are exceptionally increased by large apertures.

The new glasses produced at Schott's works, Jena, possessed in part optical qualities which differed considerably from those of the older kinds of glass. In the old crown and flint glass a high refractive index was always connected with a strong dispersion and the reverse. Schott succeeded, however, in producing glasses which with a comparatively low refraction have a high dispersion, and with a high refraction a low dispersion. By using these glasses and employing minerals with special optical properties, it is possible to correct objectives so that three colours can be combined, leaving only a quite slight tertiary spectrum, and removing secondary aberrations for two colours. Abbé called such systems "achromats." Good achromats often have as many as twelve lenses, whilst systems of simpler construction are only achromatic, and are therefore called "achromatic objectives." But an achromatic objective it is not possible to entirely remove the chromatic difference of magnification, i.e., the images produced by the red and blue rays are somewhat smaller than the images produced by the green rays. A white object is represented with blue patches on a black one with red streaks. This aberration can, however, be successfully controlled by a suitable eyepiece (see below).

A further aberration which can only be removed with difficulty, and which is often only partially corrected, is the curvature of the field, i.e., the points situated in the middle and at the edge of the plane object can not be seen clearly at the same focusing.

Historical Development.—The first real improvement in the microscope objective dates from 1830 when V. and C. Chevalier, at first after the designs of Selligge, produced objectives, consisting of several achromatic systems arranged one above the other. The systems could be used separately or in any combination. A second method for diminishing the spherical aberration was to alter the distances of the single systems, a method still used. Selligge had no particular comprehension of the problem, for his achromatic single systems were simply telescope objectives corrected for an infinitely distant point, and were placed so that the same surface was turned towards the object in the microscope objective as in the telescope objective; although contrary to the telescope, the distance of the object in the microscope is much in proportion to the distance of the image. It would have been more correct to have employed these objectives in a reverse position.

These circumstances were considered by Chevalier and Lister. Lister showed that a combination of lenses can be achromatic for only two points on the axis, and therefore that the single systems must be so arranged that the aplanatic (virtual) image-point (fig. 32) of the first order coincides with the object-point of the next system. This system will always be aplanatic. These objectives permitted a much larger aperture than a simple achromatic system. Although such systems have been made recently for special purposes, the construction was abandoned, and a more complex one adopted, which also made the production of better objectives possible; this is the projective compensation of the aberrations produced in the different parts of the objective. This proceeded on quite different lines, hinted at the possibility of such a compensation. This method makes it specially possible to diminish the chromatic aberrations of higher orders and to fulfil the sine-condition, and the chief merit of this improvement belongs to Amici. He had recognized that the good operation of a microscope objective depended essentially upon the size of the aperture, and he therefore endeavoured to produce systems with wide aperture and good correction. He used chiefly a highly curved plano-convex front lens, which has since always been employed in strong systems. Even if the object-point on the axis cannot be reproduced quite free from aberration through such a lens, because aberrations of the type of an under-correction have been produced by the first plane outer limiting surface, yet the correction with the second lens, which can be well compensated by other systems, Amici chiefly employed cemented pairs of lenses consisting of a plano-convex flint lens and a biconvex crown lens (fig. 33) and constructed objectives with an aperture of 1½. He also showed the influence of the cover-slip on pencils of such wide aperture. The lower surface of the slip causes under-correction on being traversed by the pencil, with over-correction when it leaves it; and hence the aberrations of the surface lying farthest from the object, i.e., those caused by the upper surface preponderate, an over-corrected cone of rays enters the objective. The over-correction increases when the glass of the objective is of a different type from that of the glass of the objective; the whole objective must be correspondingly under-corrected. Objectives with definite under-correction can however only produce really good images with glass over 0.004-0.005 in. in thickness. Differences of even 0.004-0.005 in. in the glass covers can be noticed by the deterioration of the image. In systems with smaller apertures variations of the thickness of the glass cover are not 80
noticeable. For this reason Amici constructed objectives of a similar aperture and focus for different thicknesses of glass covers. This expensive method was simplified in 1837 by Andrew Ross by making the upper and lower portion of the objective variable by means of a so-called correction-collar, and so giving the objective a corresponding under-correction according to the thickness of the glass cover. The variation of the focus and the aperture is little influenced. The correction-collar was improved by Wenham and Zeiss, by working the upper system upon the lower, and not the reverse; for in this way the preparation remains almost exactly focused during the operation (see fig. 14).

The injurious influence of the glass cover is substantially lessen
d if no air is admitted to the space between the glass cover and the
front lens (as in the dry-system) but if the intervening space is filled with an immersion-liquid. Amici was likewise the first to produce practical and good immersion-systems. The slight difference of the refractive index of the glass cover and the immersion-liquid involves a diminution of the aberrations, by which the objective will become less sensitive to the differences in thickness of the glass covers and admits of a more perfect adjustment. Water-immersion was introduced by Amici in 1840, and was improved by E. Hartnack in 1855.

The advantages of the immersion over the dry-systems are greatest when the embedding-liquid, the glass cover, the immersion-liquid and the front lens have the same refractive index. Such systems with a so-called homogeneous immersion were first constructed after the plan of E. Abbe in 1858 in the Zeiss workshops at the instigation of J. W. Stephenson. Cedarwood oil (Canada balsam), which has a refractive index of 1-515, is the immersion-liquid. The structure of a modern system of this type, with a numerical aperture of 1-50, is shown in fig. 35.

The most perfect microscope objective was invented by E. Abbe in 1886 in the so-called aplanochromatic objective. In this, the secondary spectrum is so much lessened that for all practical purposes it is used in the eye. In the apochromats the chromatic aberration of the spherical aberrations is eliminated, for the spherical aberration is completely avoided for three colours. Since in these systems the sine-condition can be fulfilled for several colours, the quality of the images of points beyond the axis is better. There still remains a slight chromatic difference in magnification, for although the magnification consequent upon the fulfillment of the sine-condition is the same for all zones for one colour, it is impossible to avoid a change of the magnification with the colour. Abbe overcame this defect by using the so-called compensation ocular, made with Jena glasses. Fig. 36 shows an aplanochromat of a numerical aperture of 1-40.

THE EYEPIECE OR OCULAR

The eyepiece is considerably simpler in its construction than the objective.

Its purpose in a microscope is by means of narrow cones of rays to represent at infinity the real magnified image which the objective produces. As, however, the object represents a real image, the problem is to project a transparent diapositive. It is therefore impossible to observe this image through an ordinary lens. Since many of the rays coming from the exit-pupil of the objective would not reach the eye of the observer at all, it is necessary, in order to make use of all of them, to direct the diverging rays forming the real image so that the whole of the light enters the eye of the observer. This is effected by a collective lens; it may be compared with the second part of the condenser system of a projecting lantern. The two most customary eyepieces consist in two simple plano-convex lenses, whose distance from the other is equal to half the sum of the two focal lengths. One of these is the Ramsden eyepiece (fig. 37). If the real image produced by the objective coincides with the collective lens, only the inclination of the principal rays is altered, the form of the cone being affected only to a very small extent. The lens nearer the eye, which has about the same focal length as the collective lens, is distant from it by about its focal length. The eye-lens converts diverging pencils into parallels. Both lenses together form the exit-pupil of the objective behind the eye-lens, so that this image, the exit-pupil of the total system or the Ramsden circle, is accessible to the eye of the observer. It is possible to see the whole field through this pupil by slightly moving the head and eye. In practice the real image is formed not directly on the collective lens but a little in front of it, because otherwise all the particles of dust on the collective would also be seen magnified. In the other type, the Huygenian eyepiece (fig. 38), which is much more widely used, the objective lens is in front of the real image; it alters the direction of the principal rays and somewhat diminishes the real image. In this type the eye-lens is about twice as powerful as the collective lens and makes the rays parallel. Here also the exit-pupil is accessible to the eye and through it the whole field can be seen by moving the head and eye. In both eyepieces microscopes or cross-wires are used for measuring in the plane of the real image. The Ramsden eyepiece is the most convenient for this because this plane lies in front of the collective lens, and the objective image has not yet been influenced by the eyepiece. As both eyepieces are used with very small apertures (about f/20) no attempt has been made to overcome the spherical aberrations, which are usually very slight; neither, as a rule, are the eyepieces chromatically corrected, care has only to be taken by a suitable choice of the distance of one lens from the other, that the coloured images derived from a colourless object should have the same apparent size. Since, however, the difference of chromatic magnification cannot be overcome in powerful objectives, this error is still further increased by the eyepiece. The difference of chromatic magnification cannot even be overcome in apochromats, and to cancel this aberration Abbe devised the compensating ocular (fig. 39).

The weak compensation occurs in apochromats, and to cancel this aberration Abbe devised the compensating ocular (fig. 39).
on the eyepiece the total magnification of the microscope is obtained. By the magnification of the objective is meant the ratio of the distance of distinct vision to the focal length of the objective. As powerful achromatic objectives show differences of chromatic magnification in the same way as apochromats, compensation eyepieces can be used in combination with these objectives.

**ILLUMINATING SYSTEMS**

Most microscopic observations are made with transmitted light; an illuminating arrangement is therefore necessary, and as the plane of the object is nearly always horizontal or only slightly inclined, the illuminating rays must be directed along the optical axis of the microscope.

To fully utilize the aperture of the objective system, the lamp must be placed in the same plane. In the illuminating system, when this occurs the greatest brightness will be obtained from the object. The aperture of the objective must also be increased so that the system is quite filled up, from which it follows that this method of illumination is best. With achromatic objectives, a concave mirror seems a little more favourable. A rule for a concave mirror of similar aperture is planted on the other side of the plane mirror. With the concave mirror an image of the source of light can be thrown upon the object. The distance of the concave mirror from the stage plate is about equal to its focal length. This is also the most suitable distance when diffused daylight is used, but it is too short with artificial light; the distance between the stage plate and the mirror should then be increased, so that an image of the source of light can be thrown upon the object. It is simpler to place an illuminating lens near the image plane of the source, and to choose the size of the lens so that the source falls approximately at the front focus of this lens and consequently is represented at infinity through the illuminating lens. By a correct choice of the focal length of the illuminating lens in relation to the focal length of the mirror, it is possible to choose the size of the image of the source of light so that the whole object-field is uniformly illuminated.

Too much light is useless for observing delicately coloured or colourless preparations, whose parts only become visible as a result of slight differences of diffraction. Then it is necessary to use powerfully concentrated cones of light. The apparatus must be such that the apertures of the illuminating rays can be easily altered, e.g., by inserting diaphragms in the course of the rays of the illuminating cone below the stage plate (fig. 40, PP). This construction is most easily produced by sliding or revolving diaphragms. A series of holes of different sizes perforate a revolving disk below the stage plate at an equal radial distance from the axis of the disk, so that the holes can be brought under the preparation in turn, the centre of the diaphragms always being a continuation of the optical axis of the microscope.

The so-called cylinder diaphragms (fig. 41) are also used in German microscopes. A changeable diaphragm is placed at an upper end of a short tube which can be moved in a case below the stage in the direction of the optical axis. By bringing the diaphragm nearer to the object the aperture of the objective is diminished (cf. fig. 40). These diaphragms are sometimes fitted in a slide, so that it is possible to move the diaphragm sideways and, therefore, give the correct illumination (fig. 42).

With very powerful objectives these methods are insufficient; and a condenser is fitted below the stage plate. As a rule an iris diaphragm, which can be moved sideways, is now fitted below this condenser; below is the mirror which can be moved in all directions.

**FIG. 42.—Abbe Illuminating Apparatus with Ordinary Condenser (Zeiss).**

The whole apparatus can be focused by a rack and the button s. The iris diaphragm can be regulated by the lever p; it can also be turned to one side round the pivot z so that the condenser k can be removed or changed. The correct direction can be given to the illuminating cone by the mirror m. It is often desirable to pass from direct to oblique lighting. The Abbe apparatus makes this easy. The iris diaphragm i is pushed to the side by the rack and pinion p n. The chief cone of rays then enters obliquely into the objective, the angle between the direct cone of rays and the diffraction spectrum of the first order can then become as large as again as with direct lighting, and still be taken up in the objective. Oblique lighting, however, can only be in an azimuth, so that the object must be turned in order that the details may be observed. Hence a condenser, for lighting with very oblique cones, must have about the same aperture as the objective, and therefore be of very wide aperture; they therefore closely resemble microscope objectives in construction. Especially powerful achromatic condensers are only magnified microscope objectives, with the difference that they are not corrected for the thickness of the cover slip, but for the thickness of the glass on which the object is placed. For exceptionally accurate work microscope objectives are sometimes used as condenser systems. When using immersion objectives, an immersion condenser must also be used if rays of extreme obliquity are wanted, for, in consequence of mirror reflection, rays can only come from the upper plane surface of the condenser, which have not a larger inclination to the axis than about 41°, varying according to the refractive index of the glass. In order to have the object rays pass out from the condenser, some immersion liquid must be placed between the upper surface of the condenser and the object slide. Condensers are, for this reason also constructed with apertures up to 1:40.

**Vertical Illuminators.**—Opalescent objects can only be seen by reflected light. With low magnifying systems and a large free object distance, ordinary good daylight is sufficient. If the objects have a low reflecting power, or if a slightly higher magnification is needed, the lighting can be improved by optical system.

To examine small opaque objects with a high magnification the Lieberkühn mirror, so named after its inventor, was formerly much used. This was a concave mirror, pierced in the middle, fixed to the objective, and directed towards the object and with such a
focal length that rays parallel to the axis falling upon it were united exactly upon the object. In this case the object lay upon a stage plate, whose centre had so far been made opaque, so that the rays coming from the illuminating plane mirror could not reach the objective direct, but only the rays passing the stage plate to the side of this blackened portion reached the Lieberkühn mirror, and were used in lighting. The disadvantage of this method was that only small objects could be examined. Much more easily manipulated is the parabolic side-illuminator invented by R. Beck, which can be conveniently fitted in and used for objects with different focal lengths. Its fundamental principle is that a parabolic mirror, which concentrates all the light coming from the side upon the object. To examine objects with objectives of high power and low free object distance, the apparatus for side-illumination is not suitable; a so-called vertical illuminator is used. The object is placed in the form (fig. 43) a small prism \( p \), which also revolves upon a horizontal axis, is placed as near as possible to the back lens of the objective. The edge which is the separating line of the horizontal and hypothenuse surfaces of the prism, lies approximately over the middle of the objective, so that the rays entering through the opening in the side after having been reflected by the hypothenuse surface are concentrated through one half of the objective on to the object. When observing only the other half of the objective is used. The source of light used should be arranged so that the objective throws an image of the light-source upon the object. It is best if the image of the light is not larger than the object examined, and to effect this, an illuminating lens with an iris diaphragm is placed between the source of light and the illuminator. By suitable adjustment and changing the iris diaphragm the size of the object illuminated can be controlled. The objects observed with the vertical illuminator must not have a glass cover if the dry system is employed, because the upper surface of the glass cover would send so much light back into the objective by reflection, that the image would be distorted. In order to examine covered objects with the vertical illuminator, if the immersion system is employed. Owing to the slight difference of illumination between the immersion liquid and the cover, the portion of light reflected on the cover is not noticeable.

**Dark Field Illumination.**—As was seen when discussing the physical theory, the minute details of the object cause diffractions, and can only be examined if the objective can take up at least two consecutive diffraction spectra. These diffracting details become especially distinct if the direct lighting cone of rays, the spectrum of zero order or the chief maximum, is not allowed to enter the objective and instead only two or more diffraction maxima are taken up, the details then appear bright on a dark background. In dark field illumination care has to be taken that no direct rays reach the objective and hence a good dark field illumination can be produced if the condenser system has a larger aperture than the objective. If an Abbe lighting apparatus is used a dark field diaphragm (fig. 44) can be placed in the iris diaphragm case. The central diaphragm disk keeps all the light with which the object is illuminated from the objective. The exact same effect is reached when, as is shown in fig. 45, a more powerful system D is used for a condenser, which has a blackened section on the back of the front lens of such a size that no light can enter the objective A. In this way it is only possible for diffracted rays to enter the objective.

**Apparatus for a good dark field illumination has received much attention, because in this way ultra-microscopical particles can be made visible.** This depends on the good combination of the entering cones of rays, which should be as oblique as possible; this is most easily done by mirror condensers. A number of early inventions have been revived for this purpose. Wenham's paraboloid illuminator (fig. 46) is made entirely of glass, and is in the form of a paraboloid, having on the top a spherical hole, of such a curvature that all entering rays, \( r + \frac{1}{r} \), parallel to the axis, after their reflection in the spherical hole, preserve their spherical surface perpendicularly and unite in F, the centre of the sphere. A diaphragm s is placed in the middle of the spherical surface, and this keeps back the central rays. This diaphragm is so arranged that the entering cones of rays can be altered. Another form of the paraboloid condenser allows, due to Wenham, a plane surface to be used at the upper side. Some immersion fluid must then be placed between the stage plate and the condenser in order to allow all the rays to pass out; otherwise only those rays would be able to pass out which are close to the axis of the condenser in the inside of the condenser, and are smaller than the limiting angle of the total reflection.

**Fig. 45.—Path of Rays for dark-ground illumination with fixed diaphragm in the objective.**

(Observer D can also be used as a condenser (Zeiss)).

Th. Ross's "spot lens," invented in 1855, and J. W. Stephenson's catoptric illuminator (1879), may be also mentioned. A recent condenser of very high illuminating power is due to H. Siedentopf (fig. 47). It is a double mirror system, whose reflecting surfaces are a sphere on a cone. The combination of rays is also sufficient in practice if the cardioïd surface is replaced by a spherical one.

**Fig. 46.—Wenham's Paraboloid Condenser.**

A supplementary spherical surface \( e \) is necessary for the completion of the condenser.

**Fig. 47.—Siedentopf's Cardioid Condenser.**

**Binocular Instruments.**

The stereoscopic microscope is the most suitable for finding out the space taken up by the separate parts of a preparation. (See also Binocular Instruments and Stereoscopy.) The observer has a stereoscopic impression of an object, when different perspective representations are presented to both eyes, which, through the action of the central nervous system, resolve into one impression.

One way of receiving a stereoscopic impression through a microscope is by fixing an apparatus as directly as possible above the last lens of the microscopic objective, which divides the rays passing out and directs half into each eye-piece. The half cones of rays have now semicircular sections, the diaphragms having the same form. The cones must be so directed through the divided system that the two exit pupils correspond to the interpupillary distance of the observer. The distance of the centres of the semicircular entrance pupils and their distance from the objective regulates the presence of the two perspective representations, which are presented one to the right eye and one to the left. If the perspective centres lie too near one another in the object-space, as may happen with slightly opened and weak systems, the difference of the perspective is then too slight to make any real stereoscopic impression. On the other hand, a very much exaggerated stereoscopic effect can be derived from short focused

**Fig. 47.—Siedentopf's Cardioid Condenser.**

A supplementary spherical surface \( e \) is necessary for the completion of the condenser.
systems of wide aperture. On account of the slight depth definition, short focused systems of wide aperture are not at all specially suitable for microscopic observation, because the possibility of observing objects taking up a good deal of space is too limited when such systems are used.

Professor J. L. Riddell (Quart. Journ. Micros. 1853, p. 236; 1854, pp. 15-24) published an arrangement of prisms, which, he believed, imparted a pseudomorphous impression if image-forming oculars were not used, and in 1854 a second system (fig. 48), essentially a Wheatstone pseudoscopic, appeared in print. This system gave an orthoscopic image even in ordinary eyepieces. By adopting right-angled reflection-prisms and arranging the objectpiece he erected the image. Stephenson's stereoscopic microscope (fig. 58, Plate) resembles this apparatus in all essentials. A construction of practice which has now almost fallen from use, while on the contrary an extremely simple dividing prism published by Wenham (Land. Micros. Soc. 1864, p. 100) has been exceptionally well attested in practice. It is moreover easily used than any other apparatus (see Binocular Instruments, fig. 8). A reflection-prism (fig. 49) in a setting is placed above the last surface of the objective and divides the exit rays. The group of rays from the left side of the objective can continue its way without hindrance to the right eye. The group of rays coming from the right half of the objective is reflected twice in the prism and the left exit rays of the tube containing the left eye is a little inclined towards the right tube, which is perpendicular. It can be adapted to the interpupillary distance by changing the tube slide.

If it is desired to use the instrument as a monococular, the setting with the prism at the lower end of the tube is taken away.

A second manner of making stereoscopic observations employs stereoscopic eyepieces. The first of such eyepieces was proposed by R. B. Tolles. He realized that the division of the cones of rays by prisms could only be satisfactorily performed if the prism was placed in the position of the exit pupil of the objective or in the position of the real image of this exit pupil. He employed a Nachet combination of prisms and placed the dividing prism at the spot where a special reversing system formed a real image of the exit pupil of the objective. A simple stereoscopic eyepiece was devised by A. Prazmowski who substituted a Wenham disflecting division prism at the position of the real image of the exit pupil of the objective formed by a reversing system. The newest form of a stereoscopic microscope resembles the oldest in so far as two completely separate microscopes are used. Among the oldest microscopes is the one made by Cherubin d'Orelans the observer receives a pseudomorphous impression in consequence of the image-defect which has been avoided in the instruments constructed in the Zeiss factory (fig. 50). Plate A, shows the instigation of the American zoologist H. S. Gruenough. The system of Forro prisms employed affords a convenient method of adjusting the ends of the eyepieces to the interpupillary distance. The two tubes are inclined to one another at an angle of about 14°.

The microscope is only intended for slight magnifications. The eyepiece is suggested of using both eyes for observing without having a stereoscopic perception as is perceptible to the eye. Instead of the stereoscopic eyepiece, Wenham's objective and eyepiece were placed directly before the lens. As a rule this arrangement of prisms can be exchanged for the Wenham stereoscopic reflection-prisms.

A second kind of dividing prism which directs the entire course of rays to both eyes, and thus produces identical images, was used by Powell and Leoland (fig. 50). Every ray is divided into a reflected and a refracted portion on the front side of a plane mirror. Whilst the column of the reflected portion after leaving the plate continues its way in the same direction, displaced a little to one side, the reflected portion is directed into the side tube by a reflection-prism. With these microscopes, which are not stereoscopic, objectives of any power can be used. The surfaces of the dividing prisms must be very exact, as the navigation of the image may arise from them. A microscope with two eyes can be obtained by employing the Abbe stereoscopic eyepiece.

By the supplementary use of one of Wenham's prisms every ray is again directed into a more perfect refracted and a weaker reflected one. The same image can be presented to each eye by using this eyepiece. But the stereoscopic impression is then felt. It is brought about by placing the diaphragms in the plane of the exit pupil of the microscope. By

turning the diaphragms 180° round the optical axis, the orthoscopic impression can be changed into the pseudoscopic. The mechanical arrangement of the eyepiece is such that the distance of the two exit pupils can be adjusted to the interpupillary distance.

MECHANICAL ARRANGEMENTS

Although the optical system is the first consideration in a microscope, the system is valueless if the fittings do not allow its correct use. The optical system must be kept at a certain distance and well centred, and a correct position for the object in relation to the system must be assured.

In fig. 60, Plate, the microscope is seen to consist of the heavy metal foot A, which rests on the table at three points. The whole microscope is fitted to this foot. The object can be held firmly on the stage plate B by a stage clamp, which, like the condenser and the diaphragms, is adjustable. The stage plate is the stage plate is the stage plate and stands on a block fixed to the stage plate. Likewise on the stage plate is the stage plate is the stage plate. The rough adjustment of the microscope can be made by a rack and pinion F and the fine adjustment by the screw G. The tube containing the eyepiece and the objective is double. The inner tube H is movable, making a change in the length of the tube possible. As a rule this inner tube has a mark which allows the length of the tube to be set.

It is most important the stand should be free of vibration. A fine adjustment is also necessary, in order to perform conveniently and with certainty the slight adjustments of the microscope in relation to the object. In cheap stands the rough adjustment was worked by moving the inner tube by hand, but the more convenient rack and pinion are now used almost exclusively.

For slight magnifications rough adjustment is sufficient, but with objectives of a focus below 1 in., a fine adjustment is wanted. Very different constructions are in use. Almost all are such that the whole microscope is fitted to a stage plate and is thus moved by the mechanism of the fine adjustment, and not only the objective. The most used is the micrometer screw adjustment (fig. 51). The tube carrier B fits closely on to a column A which is fixed firmly to the stage plate. The end of the column C is traversed by the micrometer screw D which is set in action by the knob E. The column A contains a powerful spiral spring, which exercises a strong pressure on the plate F fixed to the carrier B. By screwing in the micrometer, the spring is compressed and the tube lowered. By the contrary movement the spring pressure raises the tube as far as is allowed by the screw. The strong pressure of the spring practically excludes motion, which with fine adjustments is very important. Another very good adjustment is that of Messrs Swift & Sons (fig. 52). The long lever D is pressed to one side by the screw F, and is thus turned round the pin E. On the tube very near to the pin E is a cylinder C, which by the action of the screw F is very slightly raised or lowered. A double lever is used in a fine adjustment by Messrs Watson & Sons (fig. 53). According to whether the screw A or B is used, the adjustment is fine or coarse. In other fine adjustments by means of the stage plate B by cramps C. On the lower side of the stage plate (Zeiss), or a curved disk fixed to the balance wheel is turned (Leitz), or an oblique disk arranged more or less in a circle and attached to the balance wheel is revolved (Reichert). These modern adjustments are made so exact that motions can be easily measured.

is not restricted, as is the case if the analyser is used above the eyepiece. Nicol’s, Glan-Thomson prisms or similar polarization apparatus are used as polarizers and analysers. Below the analyser is a plate II of selectable microscopes may be put in the course of the rays. This small plate can also be used above the polarizer in the illuminating apparatus or in the eyepiece.

To examine crystals, especially in converging light, a condenser, movable in the optic axis, is needed above the polarizer. The image produced by the microscope objective M in its back focus plane is then observed through a supplementary microscope. The objective of the supplementary microscope, the Bertrand lens, can be applied through a window L at the lower end of the inner tube K. By using a rack and pinion movement L the supplementary microscope can be adjusted for the images. There is nearly always an arrangement for measuring the angle of incidence of the convergent light and then in parallel polarized light. This change can often be brought about by taking away or adding parts of the condenser.

**Microscopy**

It is often required in microscopic work to determine the size of objects or parts of objects.

There are three essential ways of performing this. The first method uses the objective screw micrometer. The object is placed on a slide in the plane of the stage plate and able to be finely moved by the micrometer screw, which has as fine a worm as possible. A divided cylinder is fixed to the turning knob, which thus makes it possible to measure fractions of the revolution. The revolutions of the cylinder are registered by a counter. The use of an eyepiece with a cross thread is essential to this measurement. After the microscope has been so adjusted that the image of the object to be measured falls exactly in the plane of the cross threads, the object is moved by the micrometer until one edge of the object is exactly covered by a thread. The micrometer is now read. Then the object is moved by the micrometer till the image of the other edge is covered by the thread in the eyepiece, and the micrometer is again read. The difference between the two positions gives the size of the object.

The objective screw micrometer is, however, not sufficiently delicate, and is only used when comparatively large objects are to be measured, and especially for objects whose edges do not appear at the same time in the field of view.

The second and most widely used method employs a micrometer eyepiece. In this case not the object itself but a real image which has already been magnified by the objective is measured, and obviously much more accurate results are possible. The most accurate calculations are obtained by using the screw micrometer ocular (fig. 54). Directly below the collective lens of a Ramsden eyepiece a slide δ can be moved by a micrometer screw a; the slide carries a little glass plate ε provided with a graduation. With the help of this scale the total revolutions of the screw can be read; fractions of the revolution can be read from the divided cylinder d. The scale is generally divided into hundred thousandths millimetres or thousandths of inches. A fixed mark which serves as an index is placed on the lower side of the collective lens and is seen clearly at the same time as the graduation of the movable slide. The object viewed stands at zero. The zero mark of the cylinder coincides with the index and the fixed mark is at a known division. The calculation is most convenient if the micrometer is left in the position of zero and the object is moved till one of its edges corresponds to the zero mark of the eyepiece scale. If the micrometer is then moved till another graduation corresponds to the other edge of the image the size of the image can be read off. As this method measures

---

**Fig. 53.---Double Lever Adjustment of Watson & Sons.**

**Fig. 54.---Screw Micrometer Ocular.** Sectional elevation and plan (Zeiss).
the image correctly to a few thousandths of millimetres, the object itself is measured accurately to some hundred-thousandths of millimetres, if it has been magnified sufficiently many times by a microscopic metric glass.

To keep up this degree of exactitude the magnification of the objective must be carefully ascertained, e.g., by using an objective micrometer. A fine scale with known divisions is placed on the stage plate, and by determining the distance between the graduations of the objective micrometer formed through the same objective, by means of the screw micrometer ocular, the magnification of the objective is thereby obtained. As the errors in ohmic of the micrometer are also magnified, very exact scales are necessary. When determining the magnification the microscope must be used under exactly the same conditions: neither the length of the tube nor the focal length of the objective be altered.

A fixed eyepiece micrometer is simpler and more popular. This consists of a scale on a little glass plate, which, instead of a cross wire, is placed in the eyepiece. The adjustment of the scale must be such that the image produced by the objective falls exactly in the plane of the scale.

The size of the image is determined by calculating the entire interval taken up by it. By using an objective micrometer in place of the object, the magnification of the objective can be ascertained and from this the actual size of the object. As fractions of intervals can only be estimated in this method, a measurement with such an eyepiece scale can not be as exact as with a screw micrometer ocular. However, such a determination of size is often quite accurate enough.

A third method employs a drawing prism. The object and the drawing plane are seen at the same time, and the outlines can be readily drawn. If, as before, an objective micrometer is placed below the microscope in the place of the object, and the size of a special micrometer-interval is drawn on the stage board, of the actual size of the object to be ascertained. Instead of first drawing the object and the objective micrometer, they can of course be projected at the same moment on a scale on the drawing board.

The errors attending the determination of the size of a microscopic object depend chiefly on the accuracy of the objective micrometer; any errors in the micrometer being magnified by the objective. These may be diminished by using different parts of the objective micrometer; the corrections of the eyepiece. The calculation of the size is based on the found mean value. A second error can arise through the inaccuracy of the eyepiece micrometer, and also in the case of the scale, in making as well as the thickness of the cross wire may also occasion a fault. For this reason there is sometimes employed two very narrow threads lying beside one another, and which limit the image as nearly as possible.

**THE TESTING OF THE MICROSCOPE**

The excellence of a microscope objective depends on its definition and its resolving power.

The definition is better according as the chromatic and spherical aberrations are removed; there always being some constructions some slight aberration. In consequence of these residual aberrations, every object-point is not reproduced in an ideal image, but just as a smaller or larger circle of confusion. These circles will be objectionable as soon as the details are examined.

The size of these circles depends, in the case of equal tube lengths, only on the size of the objective, and not on the focal length, exact execution being assumed. Object details will only be well seen if the aberration circles are small in comparison. The size of these details in the image depends only on the magnification of the objective, \( N = \Delta f / f \), and can by a wise choice of the magnification of the objective be brought to the right value. In the case of a suitable ocular magnification, the details will be well seen, while the aberration circles remain invisible. It is therefore possible to judge the excellence of the focusing of objectives on the strength of the definition of the over-magnification, which they permit.

E. Abbe, through the so-called delicate ray transmission, suggested a way by which the quality of the definition of objects can be more easily observed. The ray transmission, shown in fig. 55, is obtained by means of a stop K2, placed in the lower part of the image plane behind the condenser in the plane of the iris diaphragm. The entrance pupil is in this way reduced to two small separate fields, which nevertheless contain rays of all zones. It is necessary that the outside edge of the diaphragm coincides with the edge of the entrance pupil. This can be attained by drawing the iris diaphragm so far as to form the entrance pupil.

The double diaphragm is then in such a position that the edge of the outer diaphragm coincides with the edge of the iris diaphragm.

The object employed must have distinct boundaries. Abbe's tube, which has a special object carrier on which six cover glasses of exactly determined thickness (between 0.09 mm. and 0.24 mm.) are cemented. The cover glasses are silvered on their under surfaces, and in the silvering fine lines are drawn; these lines form the test object. This plate admits at the same time of a correct determination of the thickness of the cover glass, for which the best correction exists. So long as the object is not sharply focused two separate dispersion figures will be seen. The defects of the objective are revealed, e.g., two adjacent sharp images are formed, which become indistinct if they coincide, or one pencil produces a distinct, the other an indistinct image, or that the images are surrounded with coloured rings. Owing to the curvature of the image, all parts of the object are not seen distinctly at one and the same time.

The resolving power of an objective depends on its numerical aperture. The numerical aperture can be determined in two ways. A diaphragm with a very narrow hole is placed on the stage, and the microscope sharply focused on the edges of the hole. The illuminating mirror is turned aside and a graduated scale is laid on the foot of the microscope. Strong systems produce in the proximity of their back focal plane an image of the scale, which can be inspected with a weak auxiliary microscope, and the length of the visible part of the scale be ascertained. The length of the visible piece of the scale to its distance from the diaphragm on the stage gives the tangent of half the angular aperture.

The sine of the angular aperture is often employed for the determination of the apparent aperture, employed to apertometer (fig. 55). A semi-circular glass plate bears two scales, over which two black thin metal plates bent back at right angles may be moved. A little hole in the silvered plane marks the centre of this circle. Through this hole the points of the metal plates can be observed by total reflection on the surface of the apertometer. The apertometer is laid in the plane of the axis of the microscope, and the hole is sharply focused. The eyepiece being removed the image of the metal plates is sharply observed with the aid of the pupil, to find on the upper end of the tube in the place of the pupil a disk of pasteboard or metal with an axial hole. The metal plates are then moved till the points just cut off the edge of the hole, and the angular aperture can be read off. With strong systems the vanishing of the points is observed with an auxiliary microscope, formed by means of the tube. In immersion systems the immersion liquid is placed between the front lens and apertometer.

If the numerical aperture be known the resolving power is easily found. The resolving power can also be determined by using different fine test objects. Norbert's test pieces, which bear graduated groups of extremely fine and narrow divisions are very useful, while the tests of Amphileura pellucida and Sarradella gemma are often employed.

The definition of a microscope is determined from the focal lengths of the two optical systems and the optical tube length, for which \( N = 250 \Delta f f / f \). To determine the optical tube length \( \Delta f \) it is necessary to know the position of the focal planes of the objective and of the ocular. If one focuses on the inner tube, on the image situated in the back focal plane of the objective of a distant object, and then on the dust particles lying on the second condenser, so that the image of the auxiliary objectives, which admits of the auxiliary objective gives the distance of the back focal plane of the objective from the end of the outer tube. To determine the position of the anterior focal plane of the eyepiece, the eyepiece is placed on the anterior focal plane of the eyepiece downwards. An auxiliary microscope is now focused first on the image of a distant object and then on the plane of the edge of the setting. This plane can be drawn on a sheet of paper. This gives the distance of the anterior focal plane of the eyepiece from the anterior edge of the setting of the eyepiece and consequently also of the edge of the eyepiece carried by the upper end of the tube. These measurements determine the optical tube length \( \Delta f \).
There are many methods for determining the focal length of the objective. The objective to be examined is placed on the stage, and in the manner just shown, the distance of the focal planes from the eyepiece, and that to the surface plane of the front of the objective is determined. Any plane object a few yards distant can be used. If the object can be seen by using the mirror, the plane mirror must be used; then the actual size of the object and of the image produced by the objective is determined by means of the microscope itself. The distance of the object from the nearer focus of the objective is next determined. This distance is composed of the distance of the objective, the plane mirror, the distance of the object from the focal point of the objective and the stage plate from the focal point of the objective.

For the organic material placed by the microscope, which is generally only a few microns thick, the microscope is used to determine the focal length of the eyepiece. These are the dimensions necessary for determining the magnification of the microscope, viz. the optical length of the tube $L$, the focal lengths of the objective $f_1$ and of the eyepiece $f_2$.

The focal length of an objective can be more simply determined by placing an objective micrometer on the stage and reproducing on a screen some yards away by the objective which is to be examined. If the size of the image of a known interval of the objective micrometer is determined by an ordinary scale, and the distance of the image from the focal plane of the objective belonging to it is measured, then the focal length can be calculated from the ratio $\frac{y}{y'}$, in which $y$ is the size of the object, $y'$ that of the image, and $x$ the distance of the image from the focal plane belonging to it. This method of determining the magnification is also a direct one, in which it is necessary to try first for micrometers $f_3$ or $f_4$. If a drawing prism is placed above the eyepiece, and an objective micrometer is inserted, then if a scale is laid on the drawing behind the eyepiece, and a point of focus, 1 cm. distant from the exit pupil, one or more intervals of the objective micrometer can be seen projected on the scale lying on the board. The comparison of the two scales gives directly the magnification. The course of the light within the drawing prism must be taken into account when determining the distance of the scale from the exit pupil. Although this method does not give very accurate results, it is more convenient and simple than the method just described.

Dallinger, 1901); J. Henke, der Mikroskop und die Mikrophoto (15th ed. by van Heurck, 1893); W. Kaiser, Technik des modernen Mikroskopes (Vienna, 1906), deals with the practical aspects, whilst the theory is treated in M. von Rohr (Die Theorie der optischen Instrumente, Berlin, 1904) and in S. Czarlinski (Grundzüge der Theorie der optischen Instrumente; ed. by O. Eppenstein, Leipzig, 1904). (O. H.)

**MICROTOMY** (Gr. $\tau\eta\mu\alpha$, $\xi\mu\epsilon\omega\nu$, to cut), the term applied to the preparation of minute sections of organic tissue for the microscope. In 1875 the methods were new; they had developed enabled observers to achieve the most exact study of minute anatomy, in the case of small objects, which without these methods could only be investigated by the unsatisfactory process of focusing with the microscope through the solid object. It is not necessary here to detail at length the wet method of preparing sections. Briefly, the tissue is soaked in a solution of gum, or of gum and syrup, and after being frozen by ether spray, or by a mixture of ice and salt, is cut into sections either by the Rutherford, Cathcart or some similar section-cutter, or by apparatus which can be fitted to the more modern types of microtome referred to below. This method, which is to-day used mainly by pathologists, has two main disadvantages: the prolonged action of watery fluids on the tissues, and the impossibility of getting ribbons, each section having to be picked up separately.

The general processes of the dry method employed in zoological and botanical microtomy are, up to a certain point, practically identified with those used for the preservation of animals and the preparation of other branches of microscopic work. In the first place the tissue must be fixed, i.e. the protoplasm must be set or coagulated as far as possible in the condition in which it appears in life; and in the second, they must be hardened, i.e. in most cases dehydrated. Killing may be effected by asphyxiation or narcotization (nicotine, cocaine, chloral hydrate, &c.) in special cases, but is generally achieved by fixing reagents, of which corrosive sublimate and other chlorides, picric, acetic, osmic and chromic acids, alone or in combination, chromates and strong alcohol are the most usual. These serve to a great extent also as hardening agents, but alcohol, used after them, completes this process effectively, and when not too strong (70%) is the best storage fluid. The second set of processes relates to the staining, without which transparent sections are almost invisible. The stains are divisible into general stains, which dye the tissue practically uniformly and indifferently; and selective stains, which have affinity for special tissues or cell elements. Of the latter group some fasten on nuclei, others only on the chromatin of the nuclei; some on connective tissues, others on muscle fibres and so on. It is probable that the action of all these stains is not produced by definite chemical combination with compounds originally present, but it is introduced into the tissue selected. The most generally useful stains for ordinary work belong either to the cochineal series (borax-carmine, carmalum, &c.), or to the logwood series (haematoxylin, haemalum, iron haematoxylin, &c.); in both of these great improvements have been introduced of late years by Dr Paul Mayer. The activity of these stains apparently depends upon the presence of alumina or of some similar base. For more special researches, such as cytology, neuropathology, neurophysiology, and so forth, greater dependence is placed on the use of the coal-tar colours, the names of which include, amongst others, such as safranine or gentian violet, are regressive stains; that is to say, the tissues are overstained uniformly, and the superfluous colouring matter washed out either by alcohol or by weak hydrochloric acid from the unselected parts. Others, such as methyl green, are progressive—that is, the colour is brought up to the pitch required and the reaction promptly stopped. The coal-tar stains can be used singly, or in combinations of two or three. Some of the best, unfortunately, are not permanent.

A third group of stains is furnished by such reagents as silver nitrate, gold chloride, and the like (imregnation stains), which can be made not only to stain, but also to deposit a fine metallic precipitate on certain structures. In the case of small and delicate objects, the staining is done in the mass before any further preparation for sections, but with larger animals, or large pieces of resistant tissue, the stain is applied to the sections only. The processes so far mentioned are applicable to many branches of microscopic work.

When preparing tissues for sections the first step is complete dehydration, generally effected by bringing the object into absolute alcohol. It is then transferred to one of a group of reagents, which are miscible with absolute alcohol, but would form an emulsion with water, and are solvents of the embedding medium. The embedding mass in most general use is paraffin wax, melting at a temperature of 54° to 60° C., according to the character of the object and the thickness of section required. The object is transferred from absolute alcohol to benzol, chloroform, cedar oil, or similar fluid to the melted paraffin; the fluid diffuses and evaporates, leaving the tissues to be completely permeated by the paraffin. This process can be greatly hastened by the use of a partial vacuum. When impregnation is complete the paraffin is cooled rapidly, so as to assume a homogeneous non-crystalline condition, and the tissue thus comes to form part of a block of soft but tenacious material, which protects it from damage by air or damp, and can be readily cut by a razor. The block is then trimmed to the form of a triangle or rectangle, and fixed by a clamp or by local melting in the holder of the microtome.

The first automatic microtome suitable for cutting a block of tissue into a continuous series of sections was made in 1883 in the workshop of Cambridge, from a design by W. H. Caldwell and R. Threlfall. Only a single machine was made, but in 1884 twelve machines were made by the Cambridge Scientific Instrument Company from a design by Caldwell. Since then numerous excellent and simpler forms of microtome have been evolved. Some of these have distinct advantages over others, but with microtomes as with other tools—the success of the results depends very largely on the manipulator, for every one works best with his accustomed instrument. In one type of microtome the razor is attached at one end only to a heavy
MICROTOMY

block, sliding backwards and forwards in a horizontal V-groove; the paraffin block is fed to this either up a vertical guide (Schanze, Reichert, &c.) or up an inclined plane (Thoma-Jung). In another type the razor is firmly clamped at both ends, to diminish vibration, and the paraffin block advances to it at the end of a long lever on trunnion bearings (Cambridge rockers) or up a vertical guide (Minot types).

In the selection of a microtome, apart from its steadiness, rigidity, accuracy of workmanship, and so forth, it must be borne in mind that, in general, simplicity of working parts means longer life, and that an elaborate "automatic" mechanism, by which a single movement is translated into several in different directions, not only complicates the machine, but robs the operator of those alterations of pace, rigidity, pressure, &c., which are often necessitated by the varying texture in different parts of the object cut. For general use by less skilful students in a laboratory, price, simplicity and rapidity of work recommend the rocking microtome of the Cambridge Scientific Instrument Company, but it tends to fail at large or hard objects. For the all-round work of an investigator, its simplicity and finish have made Jung's sliding microtome with the Naples improvements deservedly popular for many years; it can be fitted with special apparatus for cutting cellodion and frozen objects, and it can be relied upon to cut any tissue, however difficult; but it cannot be worked as rapidly as some others, nor produce long ribbons of large objects. For this latter purpose the Minot-Jocker, Minot-Zimmermann and Reinhold-Gilley have been strongly recommended; these, however, are all of more complicated construction, with corresponding liability to uneven wear and damage; they are highly "automatic," leaving nothing but pace under control of the operator, and they are (particularly the last) expensive.

In 1910 the Cambridge Scientific Instrument Company issued a new microtome designed primarily for cutting larger sections than was possible in their earlier forms, which respectively dealt with sections 12 x 30 mm. and 30 mm. in diameter; the new instrument cuts sections measuring 150 x 120 mm. (6 x 4 in.) embedded in paraffin or cellodion and of a thickness varying from 0.002 to 0.006 mm., each division of the scale being equal to 0.002 mm. and the total distance of automatic feed being 21 mm. The construction and action of the instrument can be understood by referring to the figure; a detailed description is given, since the same principles are utilized to a greater or less extent in all sliding microtomes.

The object to be cut, having been embedded in a suitable preparation A, is fixed to a wooden block which is attached by clamps to the object-holder B. The object-holder is provided with mechanisms by means of which the height of the block is determined; this is effected by mounting the holder in a cup-shaped socket at the extremity of a brass pillar E, which can be raised or lowered and fixed in any position by a clamp. In addition, the direction in which a section is cut can be varied by adjusting the four screws, one of which is shown at C, which orientate the block. The object-holder and feeding mechanism are carried on a sliding frame which rests at three points on two guides in the frame N, N, of the instrument; and in order to secure easy running the necessary lubrication of the bearing surfaces is provided for by a groove in which oil can be placed. The motion is effected by the handle G, connected to a system of levers H, which, being constructed on geometrical principles, prevent any side-play and ensure a uniform motion. The arrangement for determining the thickness of the section cut consists of a stop-pin, which, operating through the ratchet M, causes a toothed wheel to revolve, which in turn raises the pillar K; the amount of the motion can be read from a scale L. On the return stroke the sliding carriage the stop-pin, is again actuated in such a manner that just before the knife R reaches the object-holder the mechanism depresses this part of the instrument so that the knife is not fouled; a second after its removal the motion of the stop-pin is recommenced in the direction appropriate for taking the next section. The knife R is rigidly set in two heavy brass clamps adjustable by the screws S, and these clamps are attached to the frame of the instrument by the screws T. The angle which the cutting edge makes with the frame is also adjustable, and by means of a small angular scale engraved on the knife-holders any setting can be easily determined or repeated. The knife is flat on one side and hollow-ground on the other. In using the microtome it is essential that the cutting edge of the knife points towards the end of the instrument where the handle is placed; the hollow-ground face should be uppermost, and the flat surface should not exactly stand up, but be slightly inclined so that the lower facet of the cutting edge is parallel to the frame. As to the relation of the position of the knife to the direction of motion, it is the usual practice, when paraffin sections are to be taken, to have the cutting edge at right angles to the motion when, on the other hand, cellodion preparations are being cut, the knife must be set obliquely across the frame, an angle of 30° being convenient. This obliquity is necessary in cutting thin sections. In addition it must be remembered that cellodion preparations always require lubricating when being cut, and it is also necessary to keep both the knife and the preparation constantly moistened with either 50% alcohol or cedarwood oil directly on the sections. The sections, when cut by the microtome with the knife straight and the two sides of the rectangular paraffin block parallel to it, in most cases can be got off in a continuous ribbon, each sticking to its predecessor. This very desirable result generally can be insured by a coating of softer paraffin; but if the object be large, or brittle, or of varying texture, it is safer to cut the sections singly from a triangular block with an oblique knife. The sections or ribbon are often not quite flat, but rolled, creased or compressed; they must be flattened before being attached to the slide. It is possible to carry out these two processes simultaneously by covering the carefully cleaned slide with plenty of a very dilute solution of Mayer's glycerine and albumen, and laying the sections on the fluid and the slide on a hot-plate; as the water becomes warm the sections flatten out, and as it evaporates they settle down on the slide, and are held there by the albumen (many other methods are in use). The slide is then warmed to melt the paraffin, and plunged into benzol, or some similar fluid, which removes the paraffin; thence into absolute alcohol, which dehydrates and coagulates the albumen. If the tissue has not been stained en bloc the sections can now be stained on the slide. After staining they are fully dehydrated, rendered transparent by oil of cloves, and mounted in xylol-dammar or Canada balsam. W. Giesbrecht was the first to fix sections on the slide, using a solution of shellac in cresote in 1887; and also in the same year and in the laboratory of the Naples aquarium, W. H. Caldwell first cut and fixed ribbons of sections.

For ordinary work the paraffin method excels all others for rapidity, certainty and cleanliness; but for large and hard objects, or crumbling tissues (such as ova with a large quantity of yolk), some manipulators prefer to embed in cellodion. By this method, after dehydration, the tissue is soaked in a mixture of absolute alcohol and ether; thence transferred either to increasingly strong solutions of cellodion in the same mixture or to a thin solution which is then boiled down till strong. The cellodion mass is then hardened: at first, if necessary, by drying; afterwards by a bath of chloroform or its vapour. It can then be cut in the microtome, either wet, or (if...
previously cleaned with cedar oil) dry like a paraffin block. The method is more tedious and more messy than the paraffin process; but amongst its advantages must be reckoned that little or no heat is required, and that the embedding mass is transparent, though it does not allow of such thin sections as paraffin.

The above accounts present an outline of the complex processes employed to-day, by which, on the one hand, sections 30 μ in thickness may be made through the entire human brain; and, on the other, organs visible to the naked eye may be cut into a long ribbon of consecutive sections 1 μ (one-thousandth of a millimetre) thick, every minutest fragment being retained in its proper place.

MIDAS, the name of several Phrygian kings. The first of these was said to have been the son of Gordius and Cybele, whose first priest he was, and in whose honour he founded a temple at Pessinus. Having taken the drunken Silenus back to his youthful charge Dionysus, he was rewarded by the god with the power of transforming everything he touched into gold. Finding himself in danger of starvation, even his food and drink being changed by his touch, Midas entreated Dionysus to take back the gift. By the command of the god he bathed in the river Pactolus, which henceforth became auriferous (Ovid, Metam. xi. 85-145; Hyginus, Fab. 191). Another story connects him with the musical contest between Apollo and Marsyas (or Pan). Having decided against the god, his ears were changed into those of an ass. He concealed them under a Phrygian cap; but the scent of his breath, which being unable to keep it, dug a hole in the ground and whispered into it “Midas has ears of an ass.” He then filled up the hole, thinking his secret safe; but the reeds which grew up over the spot proclaimed it to all the world. Midas with the ass’s ears was a frequent subject of the Attic satyr-drama. There is no doubt that Midas was the name of one or more real persons among whom religious legends have grown up. The name “Midas the king” occurs on a very ancient tomb in the valley of the Sangarius, the legendary seat of the Phrygian kingdom. The Phrygian monarchy was destroyed by the Cimmerians about 675 B.C., and the name Midas became a Greek tradition the representative of this ancient dynasty.

MIDDELBURG, the ancient capital of the province of Zeeland, Holland, in the middle of the island of Walcheren, 5 m. by rail N. by E. of Flushing, with which it is also connected by steam tramway and by ship canal (1873), which continues to Veere on the N. coast of the island. It is a borough and a bent district, Pop. (1905), 19,002. Middelburg contains many splendid old houses, which recall the prosperity which distinguished it until the end of the 18th century. The beautiful town-hall, built by Anton Keldermans about 1512, with a square tower 180 ft. high, and a façade adorned with statues of the counts and countesses of Zeeland and Holland, contains the valuable city archives and antiquarian and historical collections. The old abbey of St Nicholas, founded in 1150, and now occupied by the provincial council, has some fine old tapestry of the end of the 16th century. The building was added to in the 14th and 15th centuries, and partly rebuilt after a fire in 1492. It was the scene in 1505 of a meeting of the knights of the Golden Fleece, and was frequently the residence of royal visitors, including Maximilian, Philip the Fair and Charles V. The abbott of Middelburg formerly possessed a vote of his own in the Provincial States. What was formerly the nave of the abbey church is now the New Church, and the ancient choir constitutes the Choir Church. These churches are interesting for the monuments of William II., count of Holland, king of the Romans (d. 1250), the 16th century scholar Hadrian Junius, and Jan Flv. Middelburg, the inventor of the long bow, who fell in the naval war against England in 1666. The high tower (280 ft.), known as de lange Jan, standing apart from the church contains a good chime of bells. The corn exchange, the hof St Joris and the hof St Sebastian (formerly buildings belonging to the gilds of archers, and now places of amusement) also deserve mention. The museum of antiquities belonging to the Zeeland Society of Arts and Sciences (founded at Flushing in 1769, and transferred to Middelburg in 1801) contains a complete collection of the fauna and flora of the province, many maps, plans and drawings relating to Zeeland, the first telescope made by Hans Lipperhey and Zacharias Jansen in Middelburg in 1608, and some provincial Roman antiquities.

The extensive trade which Middelburg formerly carried on with the East and West Indies and with England and Flanders, was ruined by the war with England and the French occupation. But the construction of the railway in 1872, followed by the opening of the ship canal and the large dock (1876), as well as the establishment, by the aid of the chamber of commerce, of certain manufacturing industries (iron, machinery, furniture, oil and cigars), lifted it out of its isolation.

MIDDLEBORG, a town of the Transvaal, 98 m. E. by rail of Pretoria, and 251 m. W. of Lourenço Marques. Pop. (1904), 5083—of whom 2343 were whites. It is prettily situated on the high veld, 5090 ft. above the sea, on one of the head streams of the Olifants River. Middelburg is the chief town of an administrative division of the same name, and is a trading centre for a large district. It is also the centre of one of the richest coal-fields in South Africa. From some of the adjacent collieries excellent steam coal is obtained. Copper and cobalt are found in the neighbourhood.

Middelburg was chosen in 1901 as the place of conference for peace negotiations between the British and the Boers. After the occupation of Pretoria in June 1900 by Lord Roberts the Boer forces had been reduced to guerilla warfare, and Lord Kitchener, learning that the Transvaal commandants were despondent, invited General Botha to enter into negotiations, on the basis of the recognition of British sovereignty. The conference between Lord Kitchener and General Botha was opened on the 28th of February and the negotiations, which ended in failure, were protracted until the 16th of March (see Transvaal: History, § The War of 1899-1902).

MIDDELBURG is also the name of a town in the Cape Province, South Africa, 250 m. N. by W. of Port Elizabeth. Pop. (1904), 6137.

MIDDLE AGES, THE. This name is commonly given to that period of European history which lies between what are known as ancient and modern times, and which has generally been considered as extending from about the middle of the 5th to about the middle of the 15th centuries. The two dates adopted in old textbooks were 476 and 1453, from the setting aside of the last emperor in the West until the fall of Constantinople. In recent times the dates have been assigned any exact dates for the opening and close of such a period. The trend of recent historical research leads one even to doubt the validity of the very conception of any definite medieval period. The evolution of modern European society has been continuous. Progress has not been uniform. There was much retrogression with the intrusion of new barbarian races; but from their absorption by the 12th century until the 20th there is not a century in which some notable gain was not made towards the attainment of modern civilization. The correct perspective places between the summits of modern and ancient times, not a long level stretch of a thousand years, with wanders, stationary, spell-bound under the authority of the Church, absorbed in war or monastic dreams, but a downward and then a long upward slope, on both of which the forces which make for civilization may be seen at work.

It is clear that a survey of the history of these so-called middle ages—long use makes the term inevitable—must include not only the political phase, but also economics, religion, law, science, literature, &c., since all are involved in the concept. A hurried outline of each of these vital branches of our civilization will at least reveal the falseness of the usual periodization. It is only after having traced these one by one that we can properly review the process as a whole.
MIDDLE AGES

In political history, the epochal fact which marks the close of ancient times is the decline of the Roman Empire. This was a process extending over three or four centuries, in which no one date lends itself to the historian. The deposition of Romulus Augustus, the last Roman emperor in the West, in 476, was certainly not one of those events upon which the history of the Western world depends. Outwardly it did not mark the end of the Empire, but the restoration of imperial unity. The throne in Italy had become vacant before, and the restoration of unity was realized in fact under Justinian. There is no reason why the date 476 should stand out in European history more strongly than half a dozen other such dates. Yet we may say that the 5th century did witness the actual dismemberment of the Roman Empire. The new nations in Spain, Gaul, parts of Italy and Britain were forming the rude beginnings of what were to become national states in the centuries following. Western Europe was taken out of the imperial mould and broken up. This is a revolution of sufficient magnitude to be regarded as politically the opening of a new era. It had been long preparing in the economic and administrative decline of the Empire, and in the steady influx of Germanic peoples into Roman territory for over two centuries; but the power of the old civilization to absorb the new races was exhausted by the 5th century, and the political history of Europe was turned into a different path. That path, however, was not destined to end blindly in a "middle age." The line of political development marked out in the 5th century—that of the national state—still continues. The revolution in which Alaric, Theodoric and Clovis figured did not set an example for the middle ages only, as is frequently stated; its full meaning did not appear until the Peninsula War, the Prussias of Stein and Schanhorst, and even Solferino and Sedan. Thus the 5th century politically introduces not so much the history of the middle ages as that of modern Europe.

The immediate introduction, however, was a long one—so long and so distant from the later development as to constitute in itself a distinct phase. For five or six centuries—from the 5th until about the 11th—comparatively little permanent progress was made. The Germanic tribes were still adjusting themselves and slowly learning to combine their primitive institutions with the remains of those of Rome; the premature union under Charlemagne gave way before new invasions, and anarchy became crystallized in feudalism. It was not until the 12th and 13th centuries that modern national states really took shape: England with its trial by jury, circuit courts, Magna Charta and parliament; France under the strong hand of the Capetians. A political middle age certainly lay between Theodosius and William the Conqueror, or at least between Justinian and Henry II. It is difficult to grasp its vast expanse, but few students of history realize that the period from the Saxon to the Norman Conquest of England would take us as far back as from George V. to Edward I.; or that from Theodosius to Philip Augustus there is an interval equal to that between the accession of Hugh Capet and the French Revolution. This, however, is not the period most frequently termed the middle ages in political histories. It does not include those two institutions which more than any others stand in popular imagination as genuinely medieval—the papal monarchy and the Holy Roman Empire. The papacy, with its full political and religious structure under Hildebrand (Gregory VII.) in the middle of the 11th century; its political decline set in suddenly after the pontificate of Boniface VIII. at the opening of the 14th. The great age of the Empire began slightly earlier, and continued until the fall of the Hohenstaufen in the middle of the 13th century. One cannot now deny the term middle ages to the period of these two institutions. It has been consecrated to this use too long. Yet when we include under a common name two eras so distinct as this and that preceding, our term becomes so vague as to be almost valueless. Moreover, it is doubtful if this second period is really as "medieval" as it has seemed. Papal mon- archy and Holy Roman Empire were not the only political phenomena of their age, and it is possible that their vast pre- tensions have somewhat blinded historians as to their real importance. While they were struggling to enforce their claims to universal sovereignty, the royal power, less extravagant but more real, was welding together the feudal states of France and moulding the England of to-day. Compared with this obscure process—this spread of the king's peace along the highways and through the distant forest lands of the 12th and 13th centuries—papal interdicts and jubilees, however impressive their spectacles, are but fleeting shows. The chivalry of Germany pouring through Alpine passes for an Italian campaign, or a coronation, left little trace in history except the lesson of their futility. There is much in the imperial and papal histories that is merely spectacular and romantic; much that appeals to the imagination and lends itself to myth; and since the sources are abundant—the papal archives inexhaustible and the German chronicles easily accessible—an undue emphasis has been placed upon them. It is at least evident that the political middle ages were already distinguishable during the period of papal monarchy and Holy Roman Empire.

In economic history there is a more definite line traceable. The one great economic change brought about by the decline of the Roman Empire was the lessening of urban life throughout the greater part of Europe, the closing up of avenues of communication and the predominance of isolated agricultural communities. This phase began to give way in the 11th century to a commercial and industrial renaissance, which received a great impetus from the crusading movements—themselves largely economic—and by the 14th century had made the Netherlands the great manufacturing region of Europe, the Rhine a vast artery of trade, and north Italy a hive of busy cities. The discovery of America and the expansion of commerce merely readjusted conditions already highly developed. The period of isolated economy which we may term medieval lasted only from about the 5th to the 12th centuries. As for manufactures, the antique methods survived until the 18th and 19th centuries.

In religious history—to be distinguished from that of the political organization referred to above as the papal monarchy—the official recognition of the Christian Church by Galerius in 311 serves as a convenient starting-point for what we know as universal Christendom, though the slow disappearance of paganism, as distinct from Christianity, stretches over at least a century more. The Reformation of the 16th century has long been regarded as the close of the period. The real close, however, is the present day—as the result of the rationalism and science of the 18th and 19th centuries. The heroes of the Reformation, judged by modern standards, were reactionaries. Unconsciously and to its own ultimate damage the Reformation forgave the weapons of progress; but it was itself in no sense, except the institutions of 15th century Germany, what we regard as history inaugurated before the Council of Nicaea. The real change in attitude which marks the dawn of a new era came in the generation of Voltaire. And "medievalism" is only now on the defence against "modernism," both Catholic and Protestant.

In legal history there was a distinct medieval period, when Germanic customs superseeded Roman law, that most splendid of Rome's legacies. But the renaissance of law began relatively early; by the 12th century it had created a university, by the 13th it was helping to organize national states and laying the foundations for that order which the economic renaissance was already demanding.

In science there was no great product in antiquity to be lost. Compared with art or law, literature or philosophy, ancient science (in our sense) was almost insignificant. The promise in Aristotle of such production remained unfulfilled. The 17th century is not so much a Renaissance here as a mere beginning. No one can deny the general unscientific, uncritical nature of "medieval" thought. A single Roger Bacon does not relieve his age of the charge. But the middle age in science must include much of antiquity, including Plato. Philosophy was the one subject which had, clearly and definitely, a medieval period. Scholasticism, which absorbed the attention of most thinkers from about the 11th to about the
15th centuries, is so easily marked off and played so considerable a rôle in the academic history of that time, that historians often refer to it as the only intellectual interest of "medieval" men. Then, selecting some of the later and less virile scholastics as victims, they ask how men could be seriously interested in their trivialities. But these men were not all busy over the problem of how many angels could stand on a needle-point; nor were they all dominated by the religious spirit of faith or intellectual cowardice. They were searching for truth with scientific eagerness. Their very failure made possible the modern era. It is perhaps unnecessary to point out how small a proportion of the "intellectuals" were scholastics even in the 13th century.

In the realm of art the "middle ages" had already set in before Constantine robbed the arch of Titus to decorate his own, and before those museums of antiquity, the temples, were plundered by Christian mobs. The victory of Christianity—inconoclastic in its primitive spirit—was but a single chapter in the story of decline. The process was completed by the misery of the decaying empire, and by the Germanic invasions. The barbarians, however, destroyed less than has been commonly supposed. Destruction was more the production of necessity rather than of wantonness. Thus public monuments became fortresses, and antique sculpture was built into city walls. Such art as continued was almost wholly religious; for in the wilderness of the times the churches formed oases of comparative prosperity and peace, and, even in the darkest times, wherever such oases existed there the seeds of art took root. The Church architecture of the "middle ages," then developed naturally and without a break, through the Byzantine and Romanesque styles, out of the secular and religious architecture of Greece and Rome. And, with the return of comparatively settled and prosperous conditions, not only architecture but the other arts also blossomed under the influence of what was later stigmatized as the "Gothic" spirit into new and original forms. Down to the Reformation the churches continued to be, as the temples of the ancient world had been, the main centres of the arts; yet the arts were not confined to them, but flourished wherever, as in castles or walled cities, the conditions essential to their development existed. With the revival of civilized conditions in secular life, secular ideals in art also revived; the ecclesiastical traditions in painting and sculpture, which always tend to become stereotype, began in the West to be encroached upon long before the period of the "Renaissance." The 13th and 14th centuries, which witnessed the great struggle between the secular and spiritual powers in the state, witnessed also the rise of a literature inspired by the lay spirit, and of an art which was already escaping from the thraldom of the stereotyped ecclesiastical forms. Gothic sculpture was not incidentally decorative, it was an essential element in the harmony of the architectural design. The elongated kings that guard the door of Chartres Cathedral, or the portals with the Last Judgment, are a necessary element in the façade. Thus fettered, even the realism of the Gothic sculptors failed, except in rare instances, of its full expression. The plastic arts were left for Italy, where antique models were at hand, and the glory of its achievement in the 13th and 16th centuries was so great as to obscure in men's eyes what had been done before.

But this Italian renaissance was not the only one. It was but one of many; and it was concerned with the two subjects which perhaps least deeply influence the lives of the mass of men—literary humanism and art. It is obviously absurd, in the face of the foregoing fact, to regard it as the end of a middle age in anything but in its own field.

When one studies the history of Europe subject by subject, as indicated above, and not merely in a monastic chronicle of things in general, chosen according to the author's point of view, one sees the old-time framework passing away. The traditional idea of a barren middle age and a single glorious renaissance proves false. An organic study of the past reveals a more rational picture of the process which produced the Europe of to-day. Cataclysm and special creation here as elsewhere give way to evolution. The new synthesis reveals a universal decline from the 5th to the 10th centuries, while the Germanic races were learning the rudiments of culture, a decline that was deepened by each succeeding wave of migration, each tribal war of Franks or Saxons, and reached its climax in the disorders of the 9th and 10th centuries when the half-formed civilization of Christendom was forced to face the migration of the Northmen by sea, the raids of the Saracen upon the south and the onslaught of Hungarians and Slavs upon the east. That was the dark age. It left Europe bristling with feudal castles, and already alert for the march of progress. At once the march begins. Henry the Fourth sets back the Slavs and places the outposts of Christendom along the Elbe and the Oder. Otto of his son, drives the Magyars from southern Germany and establishes the East Mark (Austria) to guard the upper Danube. The restoration of the Empire in 962 marks the first milestone on the pathway of recovery. Already scholarship had found a home in monasteries planted in the heart of the German forests. The succeeding century brought the Empire to the acme of its power, until Henry III. in the Synod of Sutri, sat in judgment on the impotent and demoralized papacy. Meanwhile France had been plunged into something even in its feudal anarchy. The monks of Cluny were at work. The Capetians had begun. The great monastery of Bec was drawing the sons of northern sea-robbers to the service of that greatest civilized force, the Church. The progress made through even this darkest age may be measured by the difference between the army of Rollo and that which William the Conqueror gathered for the invasion of England.

There is a legend, current among historians from the days of Robertson and Hallam, that as the year 1000 approached mankind prepared for the Last Judgment; that the earth "clothed itself with the white mantle of churches" and like a penitent watched in terror and in prayer for the fatal dawn. Contemporary sources fail to bear out this beautiful conception. Apart from the fact that reckoning from the birth of Christ was by no means universal, and consequently the mass of men were ignorant that there was such a thing as the year 1000, one wonders how that most enduring type of architecture, the Romanesque, reached its maturity among men who thought that the earth itself was so soon to "shrive like a parched scroll." Recent scholarship has absolutely disproved this legend, founded on a few triple phrases in monastic chronicles, and still to be heard in similar contexts. The year 1000 marks no epoch in medieval history.

The latter half of the 11th century witnessed the most remarkable political creation in Europe since the days of Caesar, the papal monarchy of Hildebrand. The great scholastic controversies had already begun in the schools of France; the revival of Roman law had called forth the university of Bologna, and the canonists had begun the codification of the law of the Church. The way was already cleared for the busy 12th century, the age of Louis VI. and Henry II., of Glanvill and Suger, of Abelard and Maimonides, of Frederick Barbarossa and Alexander III., of the emancipation of French communes and cities and the independence of those of Lombardy, of the growth of gilds and the extension of commerce, of trouvère and troubadour and the beginnings of vernacular literature, of the creation of Gothic art, of trial by jury and the supremacy of royal justice. Such are but a fraction of its achievements. The 12th century stands beside the 18th as one of the greatest creative centuries in human history. The 13th like the 15th applied these creations in the transformation of society. The century of Dante was also that of the first English parliament; its vast economic expansion enabled the national state to triumph in both England and France, and furnished the grounds for the overthrow of Boniface VIII. Into the complex history of this momentous age it is impossible to go in any detail. Sufficient to say that in the opening quarter of the 14th century England and France at least stood on the brink of "modern times." Then these two nations entered upon that long tragedy of the Hundred Years' War, a calamity absolutely immeasurable to both. But during its massacres, Jacoberies, plagues and famines, the cities of Italy, growing rich with trade and manufactures, were in their turn
the centres of progress, this time in a new direction, toward the recovery of the antique past and the development of art.

This is the so-called Renaissance (q.v.). The humanists which it produced, interested only in its splendid revelations, forgot or ignored the achievements of the period which intervened between Cicero and Petrarch. Then by the genius of their work they fastened their mistaken perspective upon historians and the cultured world at large. They struck upon the unfortunate and opprobrious term “middle ages” for that which stood between them and their classic ideals. The term was first used in this sense by Flavio Biondo, whose “decades” was an attempt to block out the annals of history from 410 to 1490. His treatment fell in admirably with the ideas of his age and of that following. To Protestants the age of the papal monarchy was like the reign of Anti-Christ. Then, after the indifference of humanists and Protestant polemic, came the disgust of men of science at the scholastic philosophy—an attitude best exhibited in Bacon’s *Advancement of Learning*. The 18th century was thus trebly barred from a knowledge of genuine medieval history. Romanticism, that reaction in which Sir Walter Scott, the Schlegels and Victor Hugo so largely figured, was as far from understanding what it admired as classicism had been from what it hated. Its extravagant praise of all that savoured of the middle ages was still blind to their real progress and work. They were, for it, the ages of romance and chivalry. The view of the romanticists was as one-sided as any that had gone before. It is only with the introduction of a wider outlook in the scientific study of history that it has been possible to straighten the perspective and modify the traditional schemes.

In the purely intellectual sphere it is certainly true that the recovery of the antique world was of great importance; that it made possible genuine criticism by presenting new points of contrast and opening up fields that led away from theological quibbles. But it did not mean the “double discovery of the outer and inner world.” Mankind did not, as Burckhardt and J. A. Symonds lead one to imagine, suddenly throw off a cowl that has blinded the eyes for a thousand years to the beauty of the world around, and awaken all at once to the mere joy of living. If any one was ever awake to the joys of living it was the minnesinger, troubadour or goliard, and the world had to wait until Rousseau and Burns before its external beauty was discovered, or at least deeply appreciated, by any but a few Dutch artists. Even Goethe crossed the Alps with his carriage shutters closed. Mont Blanc is not mentioned by travellers until after the middle of the 18th century. The discovery of the outer world is a recent thing in art as well as in science. As for the claim that the “Renaissance” delivered men from that blind reliance upon authority which was typical of “medieval” thought, that is a fallacy cherished by those who themselves rely upon the authority of historians, blind to the most ordinary processes of thought. In this regard, indeed, in spite of the advance of scientific method and the wealth of material upon which to base criticism, we are still for the most part in the middle ages. The respect for anything in books, the dogma of journalistic innaccuracy which still numbers its devotees by millions, the common acceptance of even scientific conceptions upon the dicta of a small group of investigators, these are but a few of the signs of the persistence of what is surely not a medieval but a universal trait. The so-called Renaissance did much; but it did not do the things attributed to it by those who see the “middle ages” through humanist glasses.

Upon the whole, therefore, it would seem that not only was there no one middle age common to all branches of human evolution, except the period more definitely marked as the dark age, but that those characteristics which are generally regarded as “medieval” were by no means limited to a single epoch of European history. In short, the dark age was a reality; but the traditional “middle ages” are a myth. (J. T. S.)

**MIDDLESBROUGH**

MIDDLESBROUGH, a municipal, county and parliamentary borough and seaport in the North Riding of Yorkshire, England, 238 m. N. by W. from London, on the Eastern railway. Pop. (1891), 75,532; (1901), 81,902. It lies on the south bank of the Tees, 5 m. from its mouth in the North Sea, and is the centre of one of the most important iron-working districts in the world. It is wholly of modern growth, having been incorporated in 1853. Its chief buildings are a fine town-hall with lofty clock-tower and spire (1860), containing the municipal offices, free library, &c.; an exchange, county court, Devon memorial museum and Roman Catholic cathedral. Besides iron and steel works, the first of which was that of Messrs Boleckow, Vaughan & Co., there are rolling-mills, tube works, wire-mills, engineering works, oil works, chemical works, salt works and a considerable ship-building industry. The district abounds in blast furnaces. The docks are accessible to large vessels, the entrance having a depth of 32 ft. Extensive dredging operations are carried on in the river. The accommodation for shipping includes two graving docks, two patent slips, &c. The entrance to the river is protected by two breakwaters named respectively the North and South Care. The furnaces within the port produce some
MIDDLESEX, 1ST EARL OF—MIDDLESEX

2,500,000 tons of pig iron annually. Middlesex is the seat of a Roman Catholic bishop. The parliamentary borough falling within the Cleveland division of the county, returns one member. The county borough was created in 1888. The town is governed by a mayor, ten aldermen and thirty councillors. Area, 2823 acres.

The earlier history of the place is meagre. Where Middlesex now stands there were at one time a small chapel and priory founded by Robert de Brus of Skelton Castle. These were dedicated to St Hilda, and with some lands were given by de Brus to the abbey of St Hilda at Whitby in 1130. The priory fell along with the time of the Reformation, and no trace now remains beyond some stones built into the wall of a brewery. The Oak Chair in the town-hall also is made from a fragment. In 1501 there were upon the site of Middlesex only four farmhouses. In 1829 a company styling itself the Middlesex Owners bought 500 acres of land, and began building in the town. In 1830 the Stockton & Darlington railway was extended to Middlesex; four years later the town was lighted with gas; and after six years more a public market was established. The census of 1831 showed the population to be 1,544; that of 1841 showed the proportion of the growth in the past 14 years to be of importance to the town. From the year 1851, when John Vaughan discovered the presence of ironstone in the Eston hills, the town advanced rapidly.

MIDDLESEX, LIONEL CRANFIELD, 1ST EARL OF (1575-1643), was a successful London merchant, who was introduced to King James I. by Henry Howard, earl of Northampton, and entered the royal service in 1605. In 1613 he was knighted and was appointed surveyor-general of customs; in 1616 he became one of the masters of requests, and in 1619 master of the court of wards and liverys and chief commissioneer of the navy. He was returned to parliament as member for Hythe in 1624 and for Arundel in 1621. Cranfield, who was also master of the wardrobe, was responsible for many economies in the public service, and his business acumen was very useful to the king. He took part in the attack on Bacon in 1621, and although, contrary to general expectation, he did not succeed Bacon as lord chancellor, he was created Baron Cranfield in July of this year. In 1621 also he became lord high treasurier, and in September 1622 was created earl of Middlesex, losing his positions and influence shortly afterwards because he opposed the projected war with Spain, and had incurred the displeasure of the king. The county estates of Cranfield and General were in the gift of the crown, and the earl of Middlesex was impeached by the House of Commons for corruption, he was found guilty by the House of Lords in May 1624 and was sentenced to lose all his offices, to pay a heavy fine and to be imprisoned during the king's pleasure. However, he was released from prison in a few days, was pardoned in the following year, and was restored to his seat in the House of Lords in 1640. The earl's second wife was Anne Brett (d. 1670), a cousin of Buckingham's mother, whom he married somewhat reluctantly in 1621 in order to ensure Buckingham's support. Middlesex died on the 6th of August 1645, leaving with others a son James (1621-1651), and earl of Middlesex, who was a partisan of the parliamentary party during the Civil War. James was succeeded by his brother, Lionel, and when this earl died in October 1674 his titles became extinct. The first earl's daughter Frances married Richard Sackville, 5th earl of Dorset, and their son Charles was created earl of Middlesex in 1675. Two years later he became earl of Dorset, and the title of earl of Middlesex was borne by the earls and dukes of Dorset until 1843.

MIDDLESEX, a south-eastern county of England, bounded N. by Hertfordshire, E. by Essex, S.E. by the county of London, S. by Surrey, and W. by Buckinghamshire. The area is 1845 sq. m., and, excepting Rutland, the county is the smallest in England. The area outside the county of London, or extra-metropolitan area, with which this article is mainly concerned, is 2338 sq. m. It lies entirely in the basin of the river Thames, which forms its southern boundary. On the east it is separated from Essex by the Lea, the largest northern tributary of the Thames. The other rivers, in order westward, are the Brent, the Crane or Yelling Brook, and the Colne. The waters of several streams are collected in the artificial Brent reservoir near Hendon, from which the Brent flows with a circuitous course to the Thames at Brentford. The Crane, rising in the high ground near Harrow-on-the-Hill, joins the Thames at Isleworth; and the Colne, which rises on the elevated plain between Hatfield and St Albans (Hertfordshire), traverses a flat valley on the western boundary of the county, where it divides into several channels, and joins the main river at Staines. The highest ground, exceeding 400 ft. at several points, and reaching 503 ft. above Stammore, is found along the northern boundary, in a line from Stammore through Elstree, Chipping Barnet and Potter's Bar, to the River Lea. Other well-marked lines of height are those from the main line, project southward, the eastern from Whetstone through Finchley and Highgate to Hampstead, where, within the county of London, a height of 443 ft. is found on Hampstead Heath; the western being the isolated elevation on which stands Harrow-on-the-Hill. The hills skirting the Lea valley, in the neighbourhood of Enfield, are abrupt, though of no great elevation. Elsewhere the country is very slightly undulating or quite flat, as along the banks of the Thames and Lea. The Thames, however, beautifies its immediate neighbourhood, and the great bend of the river between London and Staines, the greater part of the county was formerly densely forested and sparsely populated, and the name of Enfield Chase, a royal preserve in the north-east, still recalls this condition. In modern times the visible influence of London has spread over practically the entire county. Villages have grown into populous suburbs; large institutions, for which sites adjacent to rather than within the metropolis have been found preferable, are numerous, and the development of suburban railway communications has brought fresh ground within reach of builders. The county lies entirely within the structural basin of the Thames, and, as in the neighbouring counties, the general slope of the ground and dip of the strata is towards the south-east. South of an irregular line passing from Uxbridge, north of Hayes, to Greenford, and Ealing, Park and HarrowCommons, from the upper side of the Park to Tottenham and on from that point to Enfield, the only visible deposits are the gravels, loams, brick-earth and sands laid down in former times by the Thames, with contributions by the Lea and the Colne. These alluvial deposits rise gradually northward from the Thames and westward from the Lea, in a series of gentle terraces. The earliest portions of London were built upon these terraces, because while they were dry at the surface, water could be obtained by sinking shallow wells. The alluvium has yielded many flint implements and the bones of the mammal, bear and thomopos, great elk and other extinct forms. The deep alluvium, of Hythe, London, and of West Drayton, Southall, Enfield and Tottenham.

The London clay, a marine deposit, is bluish where it has not been covered by brown loams. It reaches to the water table at the river deposits and rises to the surface north and east of the alluvial boundary indicated above. It gives rise to the undulating grassy country round Harrow, Chipping Barnet and Elstree. Below the London clay are the more sandy Reading beds, they may be seen at Harrowfield and at South Mimms; Julien occur at Pinner and Ruislip. Chalk is only visible on the side of the Colne valley at Harfield, where it is quarried, and at South Mimms. Formerly, the sandy and pebbly Ruislip beds covered all London clay area, but now only isolated patches remain, such as those on the top of Harrow, Hampstead and Highgate hills. Long after the Bagshot beds have been dug down the chalk was found by many, and it is covered by a variety of deposits; such are the pebble gravels of Stanmore Heath and the district north of Barnet, the clay and sand of Finchley, Muswell Hill and Southgate, the chalky boulder clay to be seen at Finchley, Southgate and Potter's Bar, and the drift and gravel lying on top of the basin prove the existence, beneath the chalk, of beds which do not crop out in Middlesex. The most interesting is that at Mead's Brent Road (about 1146 ft.), which is formed from the following formations: gravel and clay, 21 ft.; London clay, 64 ft.; Reading beds, 51 ft.; Thanet sand, 21 ft.; chalk, 655 ft.; upper greensand, 28 ft.; gault, 160 ft.; lower greensand, 66 ft.; Wey sands, 30 ft.; and chalk, 160 ft.

Industries.—The climate of some of the high-laying districts is particularly healthy. Little more than one-half the total area of the county is under cultivation; and the grain crops, greatly decreasing, are insignificant in the north and west counties. 1

is heavy, poor clay; but the rich alluvial soil of the Thames Valley is specially suitable for market gardens. On the outskirts of London much land was formerly devoted to market gardens.

The industry of livestock decreases; in fact, agriculture as a whole has slowly to give place to extension of building. Industries are extensive and varied. The county, which is naturally, in what part of the province is closely intersected with railways, the following companies, from east to west and south, affording communications: Great Eastern, Great Northern, Midland, London & North-Western, Great Western, Metropolitan, Great Eastern, London & South-Western. Moreover, in some parts the tramway system has been extended over a wide area from London; thus Uxbridge, in the extreme west of the county, is served. The principal roads are the Grand Junction, running west from Brentford to the Colne Valley, and then northward; with a branch (the Paddington Canal) connecting it with the Regent's Canal. There are also a number of rivers. See Agriculture and Administration.—The area of the ancient county is 181,330 acres, with a population in 1871 of 5,339,765; in 1919 of 3,535,323. At the time of the Domesday Survey the population of Middlesex, exclusive of London, was 2,302. The extra-territorial area is 149,668 acres, with a population in 1871 of 796,538. The part of the ancient county transferred to the county of London under the Local Government Act 1889 is 31,481 acres in extent, and 771 acres were then transferred to Hertfordshire; while under the London Government Act 1899 the southern part of Hornsey was transferred to London.

The capital of Middlesex is London; the county contains six hundreds. The municipal boroughs are Ealing (pop. 33,031), Hornsey (72,056). The urban districts are Acton (57,774), Brentford (19,181), Chiswick (75,896), Feltham (52,866), Finchley (22,126), Friern Barnet (11,566), Greenford (816), Hampton (6813), Hampton Wick (2666), Hanwell (16,438), Harrow-on-the-Hill (10,220), Hayes (3000), Hendon (24,800), Heston (9000), Harrow (9500), Hounslow (9000), Hither Green (850), Hounslow (13,200), Southgate (14,993), Staines (6688), Sunbury-on-Thames (3444), Teddington (14,037), Tottenham (102,547), Twickenham (25,988), Uxbridge (12,000), Wembley (4530), Willesden (114,811), Wood Green (34,233). The county is in the jurisdiction of the central criminal court, and the whole extra-territorial county is within the county police district, the name of ‘Great London’ covering it. There are one or two quarter sessions and eight petty sessions, or districts. The number of civil parishes is 50. Middlesex (extra-territorial) is within the court of sessions of the county of London, a small portion in that of Oxford, and includes 153 ecclesiastical parishes or districts, wholly or in part. The extra-territorial parliamentary divisions, each returning one member, are Ealing, Tottenham, Hornsey, Harrow, Uxbridge, Brentford and Ealing.

History.—The district which is now Middlesex was colonized in the 6th century by an offshoot of the East Saxon tribe, and derived its name from its position between the kingdoms of the East and West Saxons. In a charter dated 704 Middlesex is mentioned by name as a dependency of Essex, but soon after it acknowledged the supremacy of Mercia, and from 757 the manor of the Hundred at Harefield was held at London, and from 780 onwards at Brentford. In the 9th century Middlesex formed part of the Danelag, and in 993 Anlaf the Dane came with 93 ships to Staines. The only reference to Middlesex in the Saxon Chronicle occurs in 1011, when it was again overrun by the Danes. The conqueror's march upon London was preceded by a general devastation of the surrounding country, the effects of which are illustrated in the Domesday Survey by the diminution in land values. At this time the district north of London formed the great forest of Midlelsey, the greater part of which was deforested in the reign of Henry III. Enfield had woodlands for 2000 pigs; Ruislip for 1500 pigs; and Kingsbury, Hillingdon and Hendon for 1000 pigs each. Vineyards are mentioned at Holborn, Colham, Kenton and Kensington; fishponds at Harmondsworth and Harefield produced each 1000 eels.

As a shire Middlesex probably originated about the time of the fifth of 886, when it is described as the land dependent upon London, and in 912 is referred to as "London and the land which owed obedience thereto." During the Saxon period the extensive areas held by the church of Copenhagen, the bishop of London and his canons of St Paul's, and the abbey of Westminster were held as independent franchises, the courts for St Paul's being held at Stepney and Fulham, for Westminster at Westminster and Staines, and for Canterbury at Harrow. By charter of Henry I. (confirmed by Stephen and Henry II.) the citizens of London held Middlesex at farm for £300, with power to elect a sheriff from among their number, and by charter from John the shrievalty of both London and Middlesex was granted to the mayor and citizens in fee. By charter of 1242 other common places for the county of Middlesex were ordered to be held at the stone cross in the Strand. Under a charter of 1447 the lord mayor was authorized to nominate one of the city aldermen as justice of the peace for Middlesex. The six modern hundreds of Edmonton, Elythorne, Gore, Isleworth, Osulston, and Spelthorne have been scarcely changed since the Domesday Survey, except that Isleworth was then Honeslaw (Hounslow), while in the 12th century户籍 was a hundred of "Mimes" is mentioned, corresponding with the Domesday hundred of Edmonton. Middlesex has always been included in the metropolitan area. See London. (See also Croydon, Beckenham, Bromley, Lea valley, South London, Croydon.) See also London, Victoria County History, Middlesex. MIDDLETON, EARLS OF. John Middleton, 1st Earl of Middleton (c. 1619-1754), belonged to a Lancashire family which had held lands at Middleton since the 12th century. In early life he served as a soldier in France; later he fought against Charles I. both in England and in Scotland, being especially prominent at the battle of Philiphaugh and in other operations against the great Montrose. He held a high command in the Scottish army which marched to rescue the king in 1648, and he was taken prisoner after the battle of Preston. He joined Charles II. when that monarch reached Scotland in 1650, but he was soon at variance with the party which at that time was dominant in church and state and was only restored to favour after doing a public penance at Dundee. He was a captive for the second time after the battle of Worcester, where he commanded the Royalist cavalry, but he escaped from the Tower of London to Paris. In 1653 Middleton was chosen by Charles II. to head the projected rising in Scotland. He reached that country in February 1654, but the insurrection was a complete failure. His leader, who cannot be held responsible for this result, remained in Scotland until 1655, when he rejoined Charles II., who made
him an earl in 1636. He returned to England with the king in 1660 and was appointed commander-in-chief of the troops in Scotland and lord high commissioner to the Scottish parliament, which he opened in January 1661. He was an ardent advocate of the restoration of episcopacy, this being one reason which led to serious dissensions between the earl of Lauderdale and himself, and in 1663 he was deprived of his office. He was afterwards (1667) governor of Tangier, where he died in June 1668.

His eldest son, CHARLES, 2nd Earl of Middleton (c. 1640-1710), held several offices under Charles II. and James II., being envoy extraordinary at Vienna and afterwards joint secretary for Scotland. In 1684 he became an English secretary of state, and with Richard Graham, Viscount Preston, he had the difficult task of managing the House of Commons for James II. He was loyal to James after the king fled to France, although he remained in England. He retired as the leader of the moderate Jacobites, he sought to bring about a restoration by peaceful means. In 1693 the earl joined the exiled king at St. Germaines, where he became his secretary of state; afterwards he held the same office at the court of James Edward, the old pretender, in Flanders and in Lorraine. He was partly responsible for the unsuccessful expedition of the Jacobites to Scotland in 1707, and he resigned his office as secretary in 1713. Middleton, who had been created Earl of Monmouth by the pretender, died in 1719. His titles had been declared forfeited in 1695, but they were claimed by his son John, who died unmarried about 1746. The earl was a Protestant and, as he visited the north of Germany, he made the dying wish of James II. and joined the Roman Catholic Church.

One of Middleton’s kinsmen was SIR CHARLES MIDDLETON, Bart. (1726-1813). Having served in the navy Middleton was comptroller of the navy from 1778 to 1790, “standing out through that period of inept administration as the pillar of the service.” In April 1805, at a most critical time, he was, although eighty years of age, appointed first lord of the admiralty by Pitt and was created Lord Barham. It has been usual to regard Barham as a cipher at the admiralty board, but more recent research, especially an examination of the Barham Papers, has proved this to be the reverse of the truth. He enjoyed the absolute confidence of Pitt, and it was his experience, industry and energy which made possible the great campaign which ended at Trafalgar. He resigned office in January 1806 and died on the 17th of January 1813. His barony passed through his daughter Diana (1762-1823) to the Noels, earls of Gainsborough, by whom it is still held. The Barham Papers are being edited by Sir J. K. Laughton (vol. i. 1907; vol. ii. 1910). See also J. S. Corbett, The Campaign of Trafalgar (1910).

MIDDLETON, ARTHUR (1742-1787), American politician and signer of the Declaration of Independence, was born at Middleton Place on the Ashley river, South Carolina, on the 26th of June 1742. His family was one of the most prominent in the colony. The grandfather, Arthur Middleton (1681-1737), was president of the Council in 1721-1730 and as such was acting governor in 1725-1730, and the father, Henry Middleton (1717-1784), was speaker of the Assembly in 1743-1747 and again in 1754-1755, a delegate to the Continental Congress in 1774-1776, and its president in 1775. Arthur was a member of the South Carolina Committee of Safety, and in 1775 president of the South Carolina Provincial Congress. Like most wealthy South Carolinians of the 18th century, Arthur Middleton was educated in England—at Hackney, at Westminster School, and at St John’s College, Cambridge. He then returned to South Carolina, but soon afterwards went back to England to live, and travelled on the Continent. In 1773 he again returned to South Carolina, and in the controversies between the colonists and the home government became a leader of the Whigs. He was a member of the provincial Council of Safety in 1775-1776, and a delegate to the Continental Congress in 1776-1777. In 1778 he was elected governor of South Carolina, but owing to his dissatisfaction with the new state constitution he declined to serve. He was captured by the British at Charleston in May 1780, was exchanged in July 1781, was again a delegate to Congress in 1781-1783, and later served in the state legislature. He died on the 1st of January 1787 at Middleton Place, near Charleston.

His eldest son, HENRY MIDDLETON (1770-1846), was an orator of ability, was governor of South Carolina in 1810-1812, a representative in Congress in 1815-1819, and the United States minister to Russia from 1820 to 1830, negotiating in 1824 a convention ‘relative to navigation, fishing and trading in the Pacific Ocean,’ and to the settlement of boundary disputes on the North-West Coast. This was the first treaty between the United States and Russia.

MIDDLETON, CONVERS (1683-1750), English divine, was born at Richmond in Yorkshire on the 27th of December 1683. He graduated at Cambridge, took orders, and in 1706 obtained a fellowship, which he soon resigned upon contracting an advantageous marriage. In 1717 a dispute with Richard Bentley, who made an extortive demand on the occasion of Middleton’s being created D.D., involved him in an acrimonious controversy. He wrote several trenchant pamphlets, among them the Remarks and Further Remarks on Bentley’s Proposals for a New Edition of the Greek Testament, an endeavour to visit his grievances upon the text of the New Testament. In 1723 he was involved in a lawsuit by personalities against Bentley, which had found their way into his otherwise judicious tract on library administration, written on the occasion of his appointment as university librarian. In 1726 he offered the medical profession by a dissertation contending that the healing art among the ancients was only exercised by slaves or freedmen. Between the dates of these publications he had visited St. Petersburg, where, after considerable deliberation, he decided to return to his native land. He was preceded in his decision by the dying wish of James II. and joined the Roman Catholic Church. The cogent tract probably contributed to prepare the storm which broke out against him on his next publication (1731). In his remonstrance with Daniel Waterland on occasion of the latter’s reply to Matthew Tindal’s Christianity as Old as the Creation, Middleton takes a line which in his day could hardly fail to expose him to the reproach of impiousness. He gives up the literal truth of the primate Mosaic narratives; and, in professing to indicate a short and easy method of confuting Tindal, lays principal stress on the indispensableness of Christianity as a mainstay of social order. This was to resign nearly everything that divines of the Waterland stamp thought worth defending. Middleton was warmly assailed from many quarters, and retreated with some difficulty under cover of a sheaf of apologetic pamphlets and a more regular attendance at church. His next important publication was a Life of Cicero (1741), largely told in that statesman’s own words. Though Middleton’s reputation was much enhanced by this piece of work, there is no doubt that he drew the greater part of the scarce book of Waterland, De tribus luminosus Romanorum. The work was undertaken at the instance of Lord Hervey, in correspondence with whom also originated his dissertation on The Roman Senate, published in 1747. The same year and the following produced the most important of all his writings, the Introductory Discourse and the Free Inquiry ‘concerning the miraculous powers which are supposed to have subsisted in the church from the earliest ages.’ In combating this belief Middleton indirectly established two propositions of capital importance. He showed that ecclesiastics from all ages and countries must fight hard to distinguish between the authority due to the early fathers’ testimony to the beliefs and practices of their times, and their very slender credibility as witnesses to matters of fact. Some individual grudge seems to have prompted him to expose, in 1750, Bishop Sherlock’s eccentric notions of antediluvian prophecy, which had been published 25 years before. On the 28th of July 1750 he died at Hildersham, near Cambridge.

Middleton’s most ambitious work is obsolete from no fault of his, but his controversial writings retain a permanent place in the history of opinion lately from the scarce book of Which not appropriately be compared with Lessing. Like Lessing, the character of his intellect was captious and iconoclastic, but redeemed from mere passion by a passion for abstract truth, too apt to suffer until called into activity by some merely personal stimulus. His diction is generally masculine and
MIDDLETON, T.

harmonious. Pope thought him and Nathaniel Hooke the younger the only prose writers of the day who deserved to be cited as authorities on the language. Samuel Parr, while exposing his plagiarisms, heaps encomiums on his style. But his best qualities, his innocence of superstition and disdain of mere extraneous authorship, are rather moral than literary.

The best general view of his intellectual character and influence is to be found in Sir Leslie Stephen's English Thought in the Eighteenth Century. ch. vi. A handsome edition of his works, containing several posthumous pieces but not including the Life of Cicerio, appeared in 4 vols. in 1752 and in 5 vols. in 1755.

MIDDLETON, THOMAS (c. 1570–1627), English dramatist, son of William Middleton, was born about 1570, probably in London. There is no proof that he studied at either university, but he may be safely identified with one of the Thomas Middleton entered at Gray's Inn in 1593 and 1596 respectively. He began to write for the stage with The Old Lady, in the original draft of which, if it dates from 1599 as is generally supposed, he was certainly not associated with William Rowley and Philip Massinger, although their names appear on the title-page of 1600. By 1602 he had become one of Philip Henslowe's established playwrights. The pages of Henslowe's Diary contain notes of plays in which he had a hand, and in the year 1607–1608 he produced no less than six comedies of London life, which he knew as accurately as Dekker and was content to paint in more realistic colours. In 1613 he devised the pageant for the installation of the Lord Mayor, Sir Thomas Middleton, and in the same year wrote an entertainment for the opening of the New River in honour of another Middleton. From these facts it is being inferred that he had influential connections. He was frequently employed to celebrate civic occasions, and in 1620 he was made city chronicler, performing the duties of his position with exactness till his death.

The most notable event in his career was the production at the Globe theatre in 1624 of a political play, A Game at Chess, satirizing the policy of the court, which had just received a rebuff in the matter of the Spanish marriage, the English and Spanish personages concerned being disguised as the White Knight, the Black King, and so forth. The play was stopped, in consequence of remonstrances from the Spanish ambassador, but not until after nine days' performances, and the dramatist and the actors were summoned to answer for it. It is doubtful whether Middleton was actually imprisoned, and in any case the king's anger was soon satisfied and the matter allowed to drop, on the plea that the piece had been seen and passed by the master of the revels, Sir Henry Herbert. Middleton died at his house at Newington Butts, and was buried on the 4th of July 1627.

He worked with various authors, but his happiest collaboration was with William Rowley, this literary partnership being so close that F. G. Fleay (Biog. Chron. of the Drama) treats the dramatists together. The plays in which the two collaborated are A Fair Quarrel (printed 1617), The World Lost at Tennis (1620), an ingenuous masque, The Changeling (acted 1624, printed 1653), and The Spanish Gipsie (acted 1623, printed 1653). The main interest of the Fair Quarrel centres in the mental conflict of Captain Ager, the problem being whether he should fight in defence of his mother's honour when he no longer believes his quarrel to be just. The underplot, dealing with Jane, her concealment of the physical facts of his generality, is generally ascribed to Rowley, was suggested by a story in Giraldi Cinthio's Heptaméron. The Changeling is the most powerful of all the plays with which Middleton's name is connected. The plot is drawn from the tale of Alsemero and Beatrice-Joanna in Reynolds's Triumphs of God's Revenge against Mother (bk. i. hist. iv.), but the story, black as it is, receives additional horror in Middleton's hands. The famous scene in the third act between Beatrice and De Flores, who has murdered Piracquo at her instigation, is admirably described by Swinburne:

"That note of incredible amazement that the man whom she has just instigated to the commission of murder can be so easily as to have served her end for any end of his own beyond the pay of a professional assassin, is a touch worthy of the greatest dramatist that ever lived. . . . That she, the first criminal, should be honestly shocked as well as physically horrified by revelation of the real motive which impelled her accomplice into crime, gives a lurid streak of tragic humour to the lifelike interest of the scene; as the pure infusion of spontaneous poetry throughout redeems the whole work from the charge of vulgar subservience to a vulgar taste for the presentation or the contemplation of criminal horror."

Leigh Hunt thought that the character of De Flores, for effect at once tragic, pathetic and political, "has done anything with which he was acquainted in the drama of his time."

The underplot of the piece, though it is based on the humours of a madhouse, has genuine comic flashes. The Spanish Gipsie has a double plot based on the Fuerza de la sangre and the Gilanilla of Cervantes. Much has been said on the collaboration of Middleton with Rowley, who was much in demand with fellow-dramatists, especially for his experience in low comedy. These plays, even in scenes where the evidence in favour of one or other of the collaborators is clear, rise to excellence which neither dramatist was able to achieve at all. It was clearly no mechanical partnership. The Mayor of Queensborough is a double intrigue from a concept assigned when the actual text has been parcelled out between the collaborators.

With Thomas Dekker he wrote The Roaring Girle, or Moll Cut-Purse (1611). The frontispiece represents Moll herself in man's attire, indulging in a pipe of tobacco. She was drawn or idealized from life, her real name being Mary Frith (1584–1637), who was made to do penance at St Paul's Cross in 1612. "Worse things, I must confess," says Middleton in his preface, "the world has taxed her for than has been written of her; but 'tis the excellence of the writer to make her better than he finds her. In the play she is the champion of her sex and is equally ready with her sword and with her wits. Middleton is also credited with a share in Thomas Dekker's Honest Whore (pt. i., 1604). The Witch, first printed in 1578 from a unique MS., now in the Bodleian, has aroused much controversy as to whether Shakespeare borrowed from Middleton or vice versa. The dates of both plays being uncertain, there are few definite data. The distinction between the two conceptions has been finely drawn by Charles Lamb, and the question of borrowing is best solved by supposing that what is common to the incantations of both plays was a matter of common property. The Mayor of Queensborough is a double intrigue from a conception assigned when the actual text has been parcelled out between the collaborators.

The plays of Middleton still to be mentioned may be divided into romantic and realistic comedies of London life. Dekker had as little direct knowledge of London life as he had of the sympathetic in treatment, reader to idealize his subject. Two New Viz.: More Dissemblers besides Women. Women beware Women, of which the former was licensed before 1622, appeared in 1657. The plot of Women Beware Women is a double intrigue from a contemporary novel, Hypothelio and Isabella, and the genuine history of Bianca Capello and Francesco de Medicis. This play, which ends with a massacre appalling even in Elizabethan drama, may be taken as giving the measure—no mean one—of Middleton's untainted power in tragedy.

The remaining plays of Middleton are: Blurt, Master-Constable. Or the Spaniard Night-mare (1602) Michaelmas Terms (1607), described by A. C. Swinburne as an excellent Hogarthian comedy; The Phoenix (1607), a version of the Haroun-al-Rashid trick; The Famelie of Love (1608); A Trick to catch the Old-one (anonymously printed, 1608); Your Fine Gallants (licensed 1608); A Mad World, my Masters (1608); A Chaste Mayde in Cheapside (printed 1630), notable for the picture of Tim, the Cambridge student, on his return home; and Compassing for a Quiet Life (c. 1617, printed 1662); No Wit, No Help is a Woman's life with a happy ending (acted 1652), on the title-page of which appear also the names of Ben Jonson and John Fletcher, though their collaboration may be doubted. Eleven of his masques are extant: A tedious poem, The Wisdom of Solomon paraphrased, by Thomas Middleton, was printed in 1597, and Microcynicon, Six Smarling Satires by T. M. Gent, in 1599. Two prose pamphlets, dealing with London life, Falstaff's wife and Falstaff's horse, are printed under his initials. His non-dramatic work, however, even if genuine, has little value.
AUTHORITIES.—His works were edited by Alexander Dye (5 vols.) in 1890, and by another introduction, many other editions, and by A. H. Bullen (8 vols.) in 1885. The Best Plays of Thomas Middleton were edited for the Mermaid series (1887) by Havelock Ellis with an introduction by A. C. Swinburne. See also Miss P. G. Wiggins' Letter to the Authorship of the Middleton-Renaissance Plays (Boston, 1897), and the notice on Middleton in Professor A. W. Ward's Hist. of Eng. Dram. Ltt. (ed. 1899; ii., 493-540), which contained a full account of Middleton's Consp. Chrest. A careful examination of the parallelisms between the plays of Shakespeare and Middleton is made by D. Hugo Jung in "Das Verhältnis Thomas Middleton's zu Shakespeare" (Münchener Beiträge zur roman. u. engl. Phil. vol. xxix., 1904).

MIDDLETOWN, a market town and municipal borough in the Middletown parliamentary division of Lancashire, England, on the Irk, near the Rochdale Canal, and on the Lancaster & Yorkshire railway, 6 m. N.N.E. from Manchester. Pop. (1901), 25,782; in the south-east the St. Leonard's Off Middletown's Church of England. The oldest portion of the building (the tower arch) dates from the 12th century, but the main portion from 1412, and the south aisle from 1524. Two chapels in it contain memorials of, and are named after, two ancient Lancashire families, the Asshetons and the Hopwoods. The Queen Elizabeth grammar-school, a building in the Tudor style, was founded in 1572 by Nowell, dean of St. Paul's, London. There are a handsome town-hall and municipal technical schools. An extensive system of tramways and electric light railways connects the town with the suburbs and adjacent industrial towns. The prosperity of the town dates from the introduction of manufactures at the close of the 18th century. The staple trade is the spinning and weaving of cotton, and the other industries include silk weaving, calico-printing, bleaching, dyeing, iron-founding and the manufacture of soap and chemicals. There are collieries in the neighbourhood. The town was incorporated in 1856, and the corporation consists of a mayor, 6 aldermen and 18 councillors. Area, 4,775 acres.

MIDDLETOWN, a city and the county-seat of Dubois county, Connecticut, U.S.A., in the township of Middletown, in the south central part of the state, on the west bank of the Connecticut river, about 30 m. from its mouth, and about 15 m. south of Hartford. Pop. (1890), 9,013; (1900), 9,589, of whom 2,316 were foreign-born; (1910) census, 11,851. Within a radius of 2 m. from the city hall there was found in 1910 most of the township's population of 20,749. The city is served by two branches of the New York, New Haven & Hartford railroad, by a line of coast steamers, and by electric lines connecting with neighbouring cities and villages. The city is connected by a long highway bridge across the river, and by the New York Central and Erie railroads. Pop. in 1910, 34,243; area 46 sq. m., which is known for its brown-stone quarries. Four miles south of Middletown is Chestnut Mountain (or Bull Hill), which commands a fine view; and about 3 m. east are the "Narrow's" of the Connecticut river, where the water flows between high hills. Middletown has a number of handsome residences. In High Street stand the buildings of Wesleyan university (Methodist Episcopal), founded in 1831 by the Rev. Wilbur Fisk, who became the first president, and the Rev. Laban Clark (1758-1828), who became the first president of the board of trustees. In 1838 the town was incorporated as a city; a new church was built on the site of the old church, which was later demolished, and the last freshman class of women students under the old system entered in 1909. The university offers classical and scientific courses, and in 1898-1900 had 36 instructors, 323 students (30 being women), and a library of 79,000 volumes. In 1874-1877 the work of the first agricultural experiment station in the United States was carried on here under state supervision in Wesleyan University, with Professor Wilbur Olin Atwater (1844-1907) as director; it was then removed to New Haven. Middletown is also the seat of the Berkeley divinity school (Protestant Episcopal), founded in 1843 by the theological department of Trinity College, Hartford (now part of Yale). It was removed to Middletown in 1854, and in 1897 a faculty of 8, and 16 students; and the city has a free public library (1874) with 17,700 vols. in 1907. South-east of the city is the Connecticut hospital for the insane, and south-west of the city, the Connecticut industrial school for girls (reformatory). The total value of the factory products in 1905 was $5,664,676, an increase of 35% over that for 1900. The municipality owns and operates the waterworks.

Middletown occupies the site of an Indian village, Mattabesett or Brown-stone (from Musco-prapeset, "at a great rivulet or brook"), the principal village of the Mattabesett Indians, an Algonquian tribe which included the Wungunk, Pennacook and Montowese Indians and seems to have had jurisdiction over the whole of south-western Connecticut. The township of Middletown was settled by whites in 1650, and until 1653, when the present name was adopted, was known by the Indian name, Mattabesett. It was incorporated in 1671; and the city was chartered in 1784. Shipbuilding and commerce became the principal sources of wealth. In the middle of the nineteenth century Middletown was one of the leading cities of Connecticut, and as late as 1886 it was a port of entry; but the development of rival ports, especially New Haven, Hartford and Bridgeport, into railway centres, retarded the growth of manufacture, and commerce declined after the Civil War.

MIDDLETOWN, a city of Orange county, New York, U.S.A., on the Wallkill river, 67 m. N.N.W. of New York City. Pop. (1809) 11,977; (1900) 14,522, including 1700 foreign-born and 450 negroes; (1905, state census) 14,516; (1910) 15,313. It is served by the Erie, the New York, Susquehanna & Western, and the New York & Pennsylvania railways, and is connected by an electric line with Goshen, post (1890), 3,061. It is situated in an attractive dairy and agricultural country; and in the city and vicinity there are many summer residences. Here are the state homoeopathic hospital for the insane, a state asylum, Thrall hospital, and Thrall library. Middletown is primarily a manufacturing city, and has the car shops of the New York, Ontario & Western railway. The value of its factory products increased from $2,154,742 in 1900 to $3,356,330 in 1905, or 55.8%. The municipality owns and operates its own waterworks. Middletown was settled about 1706 and owns its early commercial importance to its being a "half-house way" (whence its name) for travellers on the Minisink Road to western New York, and it was for a time a terminus of the Erie railroad. It was incorporated as a village in 1848, and first chartered as a city in 1888.

MIDDLETOWN, a city of Butler county, Ohio, U.S.A., on the Miami river, 34 m. N. of Cincinnati. Pop. (1890), 7,683; (1900), 9,215, of whom 766 were foreign-born and 314 were negroes; (1910) 13,312. It is served by the Cleveland, Cincinnati, Chicago & St. Louis, the Cincinnati, Hamilton & Dayton, the Cincinnati, New York, Ontatio & Western central system, and a branch of the Cincinnati, Lebanon & Northern (Pennsylvania system) railways. It is the trade centre of a rich and beautiful agricultural region in which tobacco, wheat and Indian corn are the principal crops. The river furnishes considerable water-power and the total factory product in 1905 was valued at $8,537,903, an increase of 47.2% over that in 1900. The waterworks are owned and operated by the municipality. Middletown was laid out in 1826 and was named from its location between Cincinnati and Dayton; it was incorporated in 1833.

MIDDLETOWN, a city and county seat of Dauphin county, Pennsylvania, U.S.A., on the east bank of the Susquehanna river, 9 m. below Harrisburg. Pop. (1890), 5690; (1900), 5608 (340 foreign-born and 289 negroes). (1910) 5,574. It is served by the Pennsylvania and the Philadelphia & Reading railways, and by an electric line to Harrisburg. The borough has a considerable trade with the surrounding agricultural country, and owing to the proximity of the Yorkhaven power-plant (across the river) and the excellent railway service, is a manufacturing centre. The municipality owns its electric lighting plant. Middletown was founded in 1755 by Friends (from Philadelphia and other places in Pennsylvania) and Scotch-Irish, and was so named because of its position midway between Lancaster and Carlisle. It was first incorporated as a borough in 1828.

MIDDLEWICH, an urban district in the Northwich parliamentary division of Cheshire, England, 166 m. N.W. of London,

XVII. 14
MIDHAT PASHA—MIDIAN

on the London & North Western railway. Pop. (1901),
4660. It lies in open country near the river Dane, having water communications by the Trent and Mersey canal, and a branch giving access to the Shropshire Union canal. The church of St Michael and All Angels is of various periods and contains numerous monuments. In the streets not a few old buildings remain, making for picturesqueness, and a number of the fine timbered houses in which Cheshire abounds are seen in the immediate neighbourhood. Middlewich shares in the salt industry common to several towns, such as Northwich and Winsford, in this part of the county; there are also chemical works and a manufacture of condensed milk.

MIDHAT PASHA (1822–1884), Turkish statesman, the son of a civil judge, was born at Constantinople in 1822. His father, a declared partisan of reform, trained him for an administrative career, and at the age of twenty-two he was attached as secretary to Falk Effendi, whom he accompanied in Syria for three years. On his return to Constantinople Midhat was appointed chief director of confidential reports, and after a new financial mission in Syria was made second secretary of the grand council. His enemies, however, succeeded in ousting him from this post, and caused him to be entrusted with the apparently impossible task of settling the revolt and brigandage rampant in Rumelia. His measures were drastic and their success was startling. The government made him an official of the first rank and restored him to his place in the grand council. In similar vigorous fashion he restored order in Bulgaria in 1857. In 1860 he was made vizier and pasha, and entrusted with the government of Nisch, where his reforms were so beneficial that the sultan charged him, in conjunction with Fuad Pasha and Ali Pasha, to prepare the scheme for adapting them to the empire which was afterwards known as the law of the vilayets. After further administrative work in his province, he was ordered to organize the council of state in 1866, and was then made governor of Bagdad, where his success was so extraordinary, that he was attended with much greater difficulties. In 1871 the anti-reform influence of the grand vizier, Mahmoud Nedim, seemed to Midhat a danger to the country, and in a personal interview he boldly stated his views to the sultan, who was so struck with their force and entire disinterestedness that he appointed Midhat grand vizier in place of Mahmoud. Too independent, however, for the court, Midhat remained in power only three months, and after a short governorship of Salonica he lived apart from affairs at Constantinople until 1875.

From this time forward, however, Midhat Pasha's career resolved itself into a series of strange and almost romantic adventures. While sympathizing with the ideas and aims of the "Young Turkey" party, he was anxious to restrain its impatience, but the sultan's obduracy led to a coalition between the grand vizier, the war minister and Midhat Pasha, which deposed him in May 1876, and he was murdered in the following month. His nephew Murad V. was in turn deposed in the following August and replaced by his brother, Abdul Hamid II. Midhat Pasha now became grand vizier, reforms were freely promised, and the Ottoman parliament was inaugurated with a great flourish. In the following February, however, Midhat was dismissed and banished for supposed complicity in the murder of Abdul Aziz. He then visited various European capitals, and remained for some time in London, where he carefully studied the procedure in the House of Commons. Again recalled in 1878, he was appointed governor of Syria, and in August exchanged offices with the governor of Smyrna. But in the following May the sultan again ordered him to be arrested, and although he effected his escape and apprised the powers, it was apparently afterwards saw fit to surrender, claiming a fair hearing. The trial accordingly took place in June, when Midhat and the others were sentenced to death. It was, however, generally regarded as a mockery, and on the intervention of the British government the sentence was commuted to banishment. The remaining three years of his life were consequently spent in exile at Taif in Arabia, where he died, probably by violence, on the 8th of May 1882. To great ability, wide sympathies, and undoubted patriotism he added absolute honesty, that rare quality in a vizier, for he left office as poor as when he entered it.

MIDHURST, a market town in the north-western parliamentary division of Sussex, England, 12 m. N. by E. of Chichester by the London, Brighton & South Coast railway; served also by the London & South Western railway. Pop. (1901), 1674. It is pleasantly situated on slightly rising ground near the river Rother. The church of St Mary Magdalen and St Denis is a large Perpendicular building. The town retains several picturesque old houses, and in the vicinity, by the river, are the ruins of the 16th century mansion of Cowdray, burnt down in 1793. A grammar-school was founded at Midhurst in 1672 and attained some eminence. After being closed for many years it was re-opened in 1843. In 1884 a plan of improvements was opened about 4 m. from Midhurst; it bears the name of King Edward VII., who laid its foundation stone and opened it.

The name of Midhurst (Middlethorpe, Midhurstd) first occurs in the reign of Henry I. when Savaric Fitz-Cana held it of the honour of Arundel, then presumably in the king's hands. The charter of Henry I., although no longer extant, is quoted in later confirmation charters of Richard I., Henry III., Edward III. and Richard II. Franco de Bohun inherited Midhurst from his uncle Savaric Fitz-Savaric, and the De Bohuns held the lordship until 15th century when Sir David Oaken obtained it through his marriage with the daughter of the last male heir. He sold it to Sir William Fitz-William, from whom it passed to Sir Anthony Browne and descended to the viscounts Montague. Midhurst is definitely called a borough in the reign of Edward I., but the borough-court and market were probably in existence much earlier. It was governed by a bailiff, elected annually, until the office lapsed, probably early in the 19th century. In an act of 1835 it is mentioned as one of the towns which had long ceased to be municipal. No charter of incorporation is known. Midhurst returned two members to parliament from 1300–1310 till 1832, when it ceased. It was then sold in the 19th century to Sir Robert Lowther, who abandoned it and took a Tickelwick there. In the reign of Henry VI. a market was held by the burgesses every Thursday, and a fair on Whit-Tuesday, by grant from Sir John Bohun. In 1888 the fair-days were the 6th of April, the 9th of May and the 29th of October. The market-day was Thursday. Pleasure-fairs are still held on the 6th of April and the 29th of October, but there is no market.

MIDIAN (properly Medyân, so Sept.), in the Bible, one of the peoples of North Arabia whom the Hebrews recognized as distant kinsmen, representing them as sons of Abraham's wife Keturah (Gen. xvi. 12). Thus the sons of Keturah are the "incense-men," not indeed inhabitants of the far south incense-land, but presumably the tribes whose caravans brought the incense to Palestine and the Mediterranean ports. So the Midianites appear in connexion with the gold and incense trade from Yemen (Isa. lx. 9), and with the trade between Egypt and Syria (Gen. xxxvii. 28, 36). They appear also as warriors invading Canaan from the eastern desert, and ravaging the land as similar tribes have done in all ages when Palestine lacked a strong government (see GIDEON). Again, they are described as peaceful shepherds, and the pastures of the Midianites, or of the branch of Midian to which Moses's father-in-law (Jethro or Reuel, or Hobab) belonged, lay near Mount Horeb (Exod. iii. 1). The Kenites who had friendly relations with Israel, and are represented in Judg. i. 16, iv. 11, as the kin of Moses's father-in-law, appear to have been but one fraction of Midian which took a separate course from their early relations to Israel. Balaam, according to one version of the story, was a Midianite (Num. xxxii. seq.) and his association with Moab has been connected with the statement in Gen. xxxvii. 35, that the Edomite king Hadad defeated Midian in the land of Moab; (see Balaam, Edom).

1 The admixture of Midianite elements in Judah and the other border tribes of Israel is confirmed by a comparison of the names of the Midianite clans in Gen. xxvi. 4 with the Hebrew genealogies (1 Chron. ii. 46, Euphr.; iv. 17, Ephr.; Gen. xlv. 9, Hanoch). Ephr. is also associated with "Of near Hanakkiya (Hanoch), three miles near Kedesh, from Midian," and this would be a Bedouin locality mentioned by Assur-bani-pal. Ephr. is probably the Hayapa transported by Sargon to Beth-Omri (Samaria).
A place Midian is mentioned in 1 Kings xi. 18, apparently between Edom and Paran, and in later times the name lingered in the district east of the Gulf of Akaba, where Eusebius knows a city Madiam in the country of the Saracens and Ptolemy (vi. 7) places Mediana. Still later Median was a station on the pilgrim route from Egypt to Mecca, the second beyond Aila (Elath). Here in the middle ages was shown the well from which Moses watered the flocks of Sho'ab (Jethro), and the place is still known as "the caves of Sho'ab." It has considerable ruins, which have been described by Sir R. Burton (Land of Midian, 1879).

This district which has on its east Ta'jrān, a centre of civilization in the 5th century B.C., and on its south-east El-Ola whose existence as a seat of culture is possibly even older, is identified by some scholars with the eastern part of the Midianites and the Arabians. See SABARAH, Yemen. That this part of north-west Arabia had frequent intercourse with Palestine appears, certainly from its commercial relations with Gaza; and the association of the Midianite Jethro with early Hebrew legislation, as also the possibility that Mizraim ("Egypt") in the Old Testament should be taken in some cases to refer to this district, have an important bearing upon several Old Testament questions. See Mizraim.

MIDLETON, WILLIAM ST JOHN FREMANTLE BRODRICK, 9th Viscount (1856- ), English politician, was the son of the 8th viscount (1830-1907). He came of a Surrey family who in the 17th century, in the persons of Sir St John Brodrick and Sir Thomas Brodrick, obtained grants of land in the south of Ireland. Sir St John Brodrick settled at Midleton, between Cork and Youghal in 1641; and his son Alan Brodrick (1660-1728), speaker of the Irish House of Commons and lord chancellor of Ireland, was created Baron Brodrick in 1715 and Viscount Midleton in 1717 in the Irish peerage. In 1756 the title of Baron Brodrick in the peerage of the United Kingdom was created. The English family seat at Peper Harow, near Godalming, Surrey, was designed by Sir William Chambers. The 8th viscount was a Conservative in politics, who for a few years had a seat in the House of Commons, and who was responsible in the House of Lords for carrying the Infants Protection Act. His brother, the Hon. G. C. Brodrick, was for many years warden of Merton College, Oxford. As Mr St John Brodrick, the 9th viscount had a distinguished career in the House of Commons. After being at Eton and Balliol, Oxford, and serving as president of the Oxford Union, he entered parliament as Conservative member for one of the Surrey divisions in 1886. From 1886 to 1892 he was financial secretary to the war office; under secretary for war, 1895-1898; under secretary for foreign affairs, 1898-1900; secretary of state for war, 1900-1903; and secretary of state for India, 1903-1905. He lost his seat for the Guildford division of Surrey at the general election of January 1906. In March 1906 his brother, the Hon. G. C. Brodrick, was an unsuccessful candidate in the By-election, and he was returned unopposed. He married, first in 1880, Lady Hilda (d. 1901), daughter of the 9th earl of Wemyss, by whom he had a family; and secondly in 1903, Madeleine Stanley, daughter of Lady St Helier by her first husband.

MIDLETON, or MIDDLETON, a market town of Co. Cork, Ireland, on the river Owenacurra, 13 m. E. of Cork by the Youghal branch of the Great Southern & Western railway. Pop. (1901), 3,301. The river here enters a branch of Cork harbour. The surrounding hilly country is pleasant and fertile, and furnishes the town with a good agricultural trade, and there are also whisky-distilleries. Ballinscurra, 7 m. south on the estuary, serves as a small port. The grammar school was founded in 1696, and here among its students were John Philpot Curran and Isaac Butt. Midleton is governed by an urban district council.

MIDNAPORE, a town and district of British India, in the Burdwan division of Bengal. The town is 68 m. W. of Calcutta; it has a station on the Bengal Nagpur railway. Pop. (1901), 33,140. It is an important centre of trade, being the terminus of a navigable canal to Calcutta, and also the junction for the Srid branch of the Bengal-Nagpur railway. There are manufactories of brass and copper wire. It has an American mission, a municipal college, and a public library founded in 1852.

The District of Midnapore has an area of 3,286 sq. m. The general appearance is that of a large open plain, of which the greater part is under cultivation. In the northern portion the soil is poor, and there is little wood. The country along the western boundary, known as the Jungle Mahals, is undulating and picturesque; it is almost uninhabited. The eastern and south-eastern portions are swampy and richly cultivated. The chief rivers of the district are the Hughli and its three tributaries, the Rupa-narayan, the Haldi and the Rasulpur. The Midnapore high-level canal used also for irrigation runs almost due east and west from the town of Midnapore to Jalubaria on the Hugli 16 m. below Calcutta, and affords a continuous navigable channel 53 m. in length. There is also a tidal canal for navigation, 26 m. in length, extending from the Rupnarayan river. The district is traversed as well by the Bengal-Nagpur railway towards Orissa, with a branch to Chota Nagpur. The jungles in the west of the district yield lac, tussur, silk, wax, resin, fire-wood, charcoal, &c., and give shelter to large and small game. The principal exports are rice, silk and sugar; and the chief imports consist of cotton cloth and twist. Salt, indigo, silk, mats and brass and copper utensils are manufactured. Both silk and indigo are decaying industries. The population in 1901 was 2,789,114, showing an increase of 6% in the decade.

The early history of Midnapore centres round the ancient town of Tamulk, which in the beginning of the 9th century was an important Buddhist settlement and maritime harbour. The first connexion of the English with the district dates from 1760, when Mr Kasim eed to the East India Company Midnapore, Chitta-gong, and Burdwan (then estimated to furnish one-third of the entire revenue of Bengal) as the price of his elevation to the throne of Bengal on the deposition of Mir Jafar.

MIDRASH, a very common term in Jewish writings for "exposition" and a certain class of expository literature. The word also occurs twice in the Old Testament (2 Chron. xiii. 22, xxiv. 27; R.V. rather poorly "commentary").

1. Introduction.—The term (Heb. midrash from darash "to search out, enquire") denotes some explanation or exposition, which, in contrast to the more literal exegesis (technically called peshat "simple"), endeavours to reach the spirit of the text. It may be defined as a didactic or homiletic development of some thought or theme, characterized by a more subjective, imaginative and ampliative treatment. Jewish Midrash falls broadly into two classes: Halakha (q.v.) orHalak (walking, way, conduct) and Haggadah (narrative [with a purpose], homily; Aramaic equivalent Aggadah; the incorrect form Agadah rests upon a mistaken etymology). The former dealt with legal and ritual matters; it flourished in the schools and developed into the more subtle casuistry. The latter covered all non-halakic and was essentially founded on the Yedidim. It embraced historical and other traditions; stories, legends, parables and allegories; beliefs, customs and all that may be called folk-lore. It fed itself, not upon the laws, but upon the narrative, the prophetic and the poetical writings of the Old Testament, and it had a more spiritual and ethical tone than the Halaka. In both classes, accepted tradition (written or oral) was reinterpreted in order to justify or to deduce new teaching (in its widest sense), to connect the present with a hallowed past, and to be a guide for the future; and the prevalence of this process, the imagination of different examples of its working, and in particular the application of the term Midrash to an important section of Rabbinical literature complicates both the study of the subject and any attempt to treat it concisely. Apart from the popular paraphrastic translations of the Old Testament (see Targum), the great mass of orthodox Rabbinical literature consists of (1) the independent Midrashim, and (2) the Mishna which, with its supplement the Gemara, constitutes the Talmud. Both contain Halaka and Haggada, although the Mishna itself contains Halaka, and the Midrashim are more especially Haggadic; and consequently further essential reading upon Midrash must be sought in the art. Talmud. These two articles

For a careful study of the meaning of the term, see W. Bacher, Jev. Quart. Rev. IV. 400-429.
handle one of the most famous bodies of ancient literature, which, in its turn, has given rise to innumerable Jewish and non-Jewish works, and has many points of value and interest which cannot be adequately discussed here. It must suffice, therefore, to deal rather broadly with the subject, and to refer for fuller details to the special encyclopaedias, viz.: Hamburger’s Real-Encyc. für Bibel und Talmud, and the very elaborate articles in the Jewish Encyclopedia.

Warren’s Midrash.—Of the three different kinds of historical writing—the genetic or scientific, the purely narrative and the pragmatic—it is the last which has prevailed among religious historians. It is extremely difficult to avoid the subjective element in dealing with matters of fact, and the religious treatment of history is influenced, however unconsciously, by the mental environment of the writers. In giving greater prominence to events of religious importance and to their bearing upon the spiritual needs of contemporaries they view and interpret the past in a particular light, and will see in the past those growths which only in their own time have become mature. A latent significance is found, a particular connexion is traced, and a continuity is established, the true nature of which must be tested by critical students. Now, it is subjective history which we find in the earliest references to Midrash. The Midrash of the prophet Iddo (2 Chron. xiii. 22) like the Visions and the Histories of Idce and Shemaiiah (lx. 29, xii. 15) which are quoted for the lives of Solomon, Abijah and Jeroboam, are evidently quite distinct from the sources cited in the parallel portions of the later Midrash. It is known that the compiler of the former has used many novel narratives of a particular edifying and didactic stamp, and scholars are practically unanimous that they are subsequent to the age of the Israelite monarchy and present a picture of historical and religious conditions which (to judge from earlier sources) is untrustworthy. At the same time various details (as comparison with the Book of Kings shows) are relatively old and, on a priori grounds, it is extremely unlikely that the unhistorical elements are necessarily due to deliberate invention or perversion rather than to the development of earlier traditions. The religious significance of the present connexion is, however, dominant, and the past is idealized from a later standpoint; and whether the narratives in Chronicles are expressly styled Midrash or not, they are the fruit of an age which sought to inculcate explicitly those lessons which, it conceived, were implied in the events of the past. The value of the book lay not in history for its own sake, but in its direct application to present needs. But the tendency to reshape history for the edification of later generations was no novelty when Chronicles was first compiled (about 4th cent. B.C.), Pragmatic historiography is exemplified in the continued additions and embellishments of the Book of Samuel, which is characterized by the presence of “apocryphal” writers, i.e. allied to Deut., especially the secondary portions; and there are many relatively early narratives in which the details have been modified, and the heroes of the past are the mouthpiece for the thought of a later writer or of his age. Numerous instructive examples of the active tendency to develop tradition may be observed in the relationship between Genesis and the “Book of Jubilees,” or in the embellishments of Old Testament history in the Antiquities of Josephus, or in the filling up of the gaps in the diverse traditions of the famous figures of the Old Testament (Moses, Noah, Enoch, Abraham, Moses, Iisrail, Ezra, &c.), as they appear in non-canonical writings. In such cases as these one can readily perceive the different forms which the same material elements have assumed, and one may distinguish the unreliable accretions which are clearly later and secondary. Accordingly, when there are narratives which cannot be tested in this manner, they show how all the internal marks of didactic expansion and date from an age much later than the times with which they deal, their immediate value will not necessarily be in the details which appear to be the result of a critical interest, but in their concept and expression of tradition and phases of thought. So far then, Midrash tends to include moralizing history, whether we call it narrative or romance, attached to names and events, and it is obviously exemplified whenever there are unmistakable signs of untrustworthy amplification and of some explicit religious or ethical aim colouring the narrative. This, however, is only one of the aspects which have to be taken into consideration when one advances to the Rabbinical Midrash.

For Old Testament “Midrash” see further K. Budde, Zeitschr. f. all-est., i. 37, seq., and commentaries on Chronicles (see also, for instance, Budde, Die geistigenErhebnisse, etc., 342). The elaborate study by the Jewish scholar Zunz (Die gesteiertenthlichen Vorlange, c. xxii.) is also valuable for bridging the gulf between the canonical and the non-canonical traditions and for its just attitude to the criticism of historical traditions. The rigid line between fact or fiction in religious literature, which readers often wish to draw, cannot be consistently justified, and in studying old Oriental religious narratives it is necessary to realize that the teaching was regarded as more essential than the method of presenting it. “Midrash” which may be quite useless for historical investigation may be appreciated for the light it throws upon forms of thought. Historical criticism does not destroy the reality of the ideas, and hence may be as worthy of study as the apparent facts they clothe, they thus indirectly contribute to the history of their period. In any case, while the true historical kernel of the Midrashic narrative is lost, the Apocalyptic (Eschatological, Judaic) element of dispute, the teaching to which it is applied stands on an independent footing as also does the application of that teaching to other ages.

3. Continuity of Literature and Material.—Amid obscure vicissitudes in the 7th to 5th centuries, b.c., the Canonical books of the Old Testament gradually began to assume their present shape (see PALESTINE: History). The internal peculiarities show that the compilations are the much edited remains of a larger body of literatures, and that the compiler has endeavoured to suppress all evidence of the older sources which did not at once perish. There is literary critical evidence for late insertions by exilic or later compilers; the compiler of Chronicles apparently refers to accessible works; and there is a close material relationship between the Old Testament and later literature. All this suggests that Old Hebrew writings, apart from those preserved in the Canon, persisted to a relatively late period. No a priori distinction can be made, and no precise chronological line can be drawn between the books of the Canons (Canticles, Ecclesiastes, Esther, Ezekiel and Proverbs), which had been at one time or another subjects of debate (see Rabbinic and later commentaries on Chronicles); and the Apocrypha are not supposed to be of the same age as the rest. The Christian Maccabees and Tobit, were “allowed”); and the intimate relation between them appears in the character of the “Wisdom Literature” (e.g. Proverbs, and the Wisdom of Solomon), in the treatment of the stories of Esther and Daniel (the history of Susanna), and also in the twofold recensions Ezra and 1 Eedras. Historical or narrative Midrash is exemplified in the “canonical” books Daniel, Esther, Jonah and Ruth, and in the “apocryphal” stories of Daniel (viz. Susanna, where the point lies in the name Daniel; God is judge “), Esther, Judith, Tobit (and the Apigir), and various sections of the “Old Testament” (viz. 1 Esdras, or the sequel of which belongs to the canonical Ezra), and the martyrdom of Eleazar (2 Macc. vi. seq., compare 4 Macc.). This is not the place to notice the course of Jewish literary activity in Palestine or Alexandria, whether along the more rigid lines of Pharisaic legalism (the development of the canonical “priestly” law), or the popular and less scholastic phases, which recall the earlier apocalyptic tendencies of the Old Testament and were cultivated alike by early Jewish and Christian writers. But after the fall of Jerusalem, partly through the need for systematising the traditional post-biblical law, and partly through disputes with the Christians, orthodox Rabbinism received the stamp which has since characterized it. The traditional or oral law was codified in the Mishna (see TALMUD, § 1 seq., the Canon was 1 Esa. 3. 14 (see G. F. Moore, Ency. Bib. “Historical Lit.,” col. 2085, middle), 2 Sam. ix.-xx., &c.)
fixed, and the fluctuations in the MSS. of the Old Testament (which, like the numerous variations in the Septuagint, complicated exact exegesis) gave way to what was virtually a single text. Moreover, the important body of apocryphal and pseudopigraphical literature, with all its links between Christianity and Judaism, fell into disfavour on both sides. This literature is especially valuable because it illustrates contemporary Jewish thought with which Jesus and his followers were familiar; it thus fills the gap between the Old Testament and the authoritative Rabbinical Midrashim which, though often in a form several centuries later, are not rarely preserve older material.1

1 A few miscellaneous examples of related Midrashic details may be cited:

i. The book of Jubilees (a haggadic and halakic Midrash on Genesis, about 2nd century B.C.), contains the story of the war between Amorite Kings and Jacob (ch. xxxiv.). This is known to the probably contemporary Testament of Judah and to much later Midrashim (Mid., Wayyag'eb, Vaq'eq Shim'on, also the apocryphal "book of Jashar"), and is evidently connected with the cryptic allusion to the capture of Shechem in Gen. xviii. 22 (R.V. marg.). Unless we suppose that the latter was suddenly added into the stories which thenceforth persisted, it may be inferred that an old extra-canonical tradition (for which a case can be made) continued to survive the compilation of Genesis (q.e.r.) and ultimately entered the Midrashic compilation to some extent. The probability of such a tradition—the merest hint of which happens to be preserved in Gen. loc. cit.—does not prejudice the problem of its origin or accuracy; in Jud. the story is useless for Jacob's history, and was probably preserved by a recollection of more recent events in the Maccabean age.

ii. A curious account of war between Egypt and Canaan after Joseph's death is given in Gen. xxv. 17-40, and is connected with details (burial of Jacob's sons at Hebron) recorded by Josephus (Ant. ii. 8). Josephus in turn has another story wherein Moses leads the Egyptians against Ethiopia (Ant. ii. 10), for parallels in the court of Moses, etc. (Gen. ch. 19, col. 2006 seq.), and this is found in the late chronicles of Jerahmeel and the Book of Jashar (cf. also Mid. Dibré ha-yamim chel-Mishle; see Jew. Ency. viii. 573 seq.). The same mention is found in Gen. xix. 9 (whereby certain characters of the text would imply speculation), and the latter with the Cushite wife of Moses; but although one may grant that the canonical sources do not by any means preserve all the older current traditions, the contents of the latter cannot be recovered from the later persisting Midrashim.2

iii. The allusion in Jude v. 9 to the contention of the archangel Michael for the body of Moses belongs to a group of traditions which have been collected by K. II. Charles (Assumption of Moses, pp. 105 seq.), and it appears that the incident was familiar to Clement of Alexandria, Origen and other early writers. Moreover, Jude v. 13 ("the ascension of the Last Testament") is referred to by Moses, which has other parallels in Matt. xxvii. 36; Acts iii. 38 seq. (ibid. pp. lxxxii seq.). Here may be added Jannes and Jambras, who withstood Moses (2 Tim. iii. 8); these or related names were known to Athenaeus (Deipnosophist., iv. 22 seq.) and to Plutarch (first half of the 1st century, Origen (who refers to a book of Jannes and Mambres), and various earlier and later Jewish sources; see I. Abrahams, Ency. Bib. col. 2327 seq.; H. St. J. Thackeray, Relig. of St. Paul to cont. Note, "Jewish thought" (London, 1909), pp. 80 seq.iii.

iv. Jewish traditions of Abraham in Ur of the Chaldees recur in the Targums, Midrashic works, and earlier in the book of Jubilees (ch. xii., ed. Charles, p. 91; cf. also Judith v. 6 seq.). The legends of his escape from a fiery furnace may have a philo-historical (i.e. interpreted as "fire"), but the allusion to the redemption of Abraham in Isa. xxii 22 seems to indicate that older tradition was fuller than the later, whereas Genesis, as a whole, and the Midrashic connection of the link connecting the Old Testament with Rabbinical thought.

v. Not to multiply examples further, it may suffice to refer to the apparent belief that the serpent tempted Eve to unchastity (Gen. iii. 15; R.V. marg.; cf. Gen. iv. 24); (d) the descent of the angels upon earth (Gen. vi. 1 seq.; Jude 6, 14 seq., see Charles, Jude p. 33 seq.); Clement-Ganneau, Quai, Statements of the Pal. Explor. Fund, 1903, pp. 233, 240; and see also H. R., Akhbar, see Jew. Ency. viii. 372 seq. 

The gap between the Midrashic developments of the story of Esther in Josephus, the Greek and Old Latin versions of the Targums and the later Jewish sources (see e.g. L. Paton, Comment. on Esther pp. 20, 100 and passim); and finally (d) the numerous minor miscellaneous parallels noticed in recent annotated editions of the

1 On the history of his intermediate stage see E. Schürer, Hist. of the Jews, ii. 233 seq.; L. Levine, Innerhalb der Hymnen im Zeitalter Jesu (Berlin, 1905); W. Fairweather, Background of the Gospels (Edinburgh 1908). Also see Apocryphic Lit. and Apocalyptic Lit.

2 Note also the allusion to the wisdom of Solomon in ii. 22, upon which contemporary writings are pretty well informed.

4 So Aquila, the first Jewish Christian, follows the Septuagint (see Jewish Encyclopedia, xlvii. 30-33); see H. L. Strack, Einleitung in den Talmud, Leipzig (1898), p. 110-131.

6 The Talmud Moed Qatan, 7a, and New Testament (I Cor. ix. 1, I Tim. v. 18) respectively.
Christian and Rabbinical teaching. Similarly the application of Hos. ii. 23, not to the scattered tribes of Israel, but to the Gentiles, is common to the Mishna and to Romans ix. 25 seq. (Sanday and Headlam, Comment. ad loc.). The Apostle Paul, once a disciple of the famous Rabbi Gamaliel, uses in 1 Cor. x. 4 ("the spiritual rock that is with them unto this day") a fancy that he identifies the "rock" with Christ, he diverges from the Alexandrian Philo who had identified it with Wisdom or the Word of God. Moreover, not only are passages thus taken out of their context, but they are combined, especially when they contain the same words or phrases, or appear to have the same or similar thoughts or aims. The Talmud, with a reference to Prov. xxxi. 14 ("she bringeth her food from afar"), says "the words of the Torah are poor (or deficient) in one place but rich in another." Hence in the Mid. Sifré on Numbers xv. 30, "ye shall not seek after...your own eyes" is explained to refer to adultery, after the words of Samson "she is pleasing in my eyes" (Judg. xiv. 3); and on Deut. vi. 5 it charges man to love the Lord "with all thy soul...even if he should take away thy soul," the teaching being based upon Ps. xlv. 22. Similarly, in the New Testament, after the same method, Mal. iii. 1 and lx. 3 (linked by the phrase "to prepare the way") are combined in Mark i. 2 seq.; Abraham's faith (Gen. xv. 6) and temptation (xxiii. 1) are associated in James ii. 21-23, as also in Jewish thought more especially by other quotations, Paul enunciates the universality of sin (Rom. iii. 10 sqq.) and the doctrine that Christians are God's temple (2 Cor. vi. 16 sqq.). Proceeding upon such lines as these, the Jews weave together their Midrashic homilies or sermons where, though we may find much that seems commonplace, there are illuminating parables and proverbs, metaphors and similes, the whole affording admirable examples of the contemporary thought and culture, both of the writers and—what is often over looked—the level of the recipients or their readers. Like many less ancient discourses, the Midrash is apt to suffer when read in cold print, and they are sometimes judged from a standpoint which would be prejudicial to the Old Testament itself. But they are to be judged as Oriental literature and if they contain jarring extravagances and puerilities, one may recall that even in modern Palestine it was found that the natives understood Robinson Crusoe as a religious book more readily than the Pilgrim's Progress (J. Robertson, Early Ed. of Israel, 1852, p. 66). In making allowance for the defects (without which they would probably not have appealed to the age) it must be remembered that some of the Rabbinical literature was recognized that the Midrashic Haggada was not always estimable.

An interesting example of combined quotation is illustrated in Matt. xii. 4-8, where the teaching of Jesus on the law of the Sabbath rests upon 1 Sam. xxi. 2-5, Num. xxviii. 9 seq. and Hos. vi. 6. A propos of this law the Rabbis' arguments are worth noticing. Apparently the severe rules laid down in Jubilees 8-12 (sect. R. II. Charles, ad loc.) were exceptional. It was allowed that the Sabbath need not be rigorously kept, and this was justified by Exod. xxxi. 13, where the singular use of the restrictive particle ak (EV "very") supported the teaching that other Sabbaths need not be observed. Also, from the words "holy unto you" (v. 14) it was taught that the Sabbath is given to you to decrees in case of need, but thou art not given the Sabbath. This was further substantiated (v. 20 "until it fall") (Talm. Shabb. 194a). Furthermore, the Passover Lamb could be sacrificed on the Sabbath, and justification for this was found in Num. ix. 2 "in its season" (Pesah. 66a). See further on this subject, and on the evasions of the Sabbath law S. Schecter, Studies in Judaism, pp. 297 seq.; ibid. in C. G. Montefiore, Hibbert Lectures (for 1862), Appendix; ibid. Hastings’ Dict. Bibl. v. 63, and also S. R. Driver, Hastings’ Dict. iv. 320 seq. With regard to the evasions, see C. H. McNeile on Matt. xii. 5; John vii. 23; "the à priori elements of law (and perhaps [these verses] were due to later reflexion on the part of Christians who had realized the inadequacy of the law") (Swete’s Camb. Bibl. Essays, 1895, p. 172). Illustrating Rabbinical methods of exegesis in the New Testament, see McNeile, "Our Lord’s use of the Old Testament"; Briggs, op. cit. pp. 436, sqq., and Thackeray, op. cit. (ch. vii. "use of the Old Testament", ch. viii. "Sabbath") Paul the latter observes (Rom. x. 5, seq., 16 seq.), and the argument in the sequence: statement, objection and reply, appears already in the book of Malachi (q.v.).

5. The Jewish Midrashim.—The earlier stages in the growth of the extant Rabbinical Midrashim cannot be traced with any certainty. Although there are several allusions to early written works, other references manifest an objection to the writing down of Haggada and Halaka. Perhaps it was felt that to preserve uniformity of teaching in the schools it was undesirable to popularize the extant collections, or perhaps the references must be reconsidered in the light of those significant changes after the fall of Jerusalem which have been mentioned above (§ 3). However this may be, the independent Ḥalakot (where the oral decisions are interpreted or discussed on the basis of the Old Testament transcribed in the schools and arranged according to their subject in the Mishnah and Tosephah (Talm. R. ii. 1), while in the halakic Midrashim (where the decisions are given in connection with the biblical passage from which they were derived) they follow the sequence of the text of the Old Testament. The Haggada was likewise collected according to the textual sequence of the Old Testament. But the sermons or discourses of the homiletic Midrashim are classified according to the reading of the Pentateuch in the Synagogue, either the three year cycle, or else according to the sections of the Pentateuch and Prophetic books assigned to special and ordinary Sabbaths, and festival days. Since the latter are sometimes styled Pesı̂ṯa ("section"). The homiletic Midrashim are characterized by (a) a proem, an introduction based upon some biblical text (not from the lesson itself), which led up to (b) the exposition of the lesson, the first verse of which is more fully discussed than the rest. They conclude (c) with Messianic or consolatory passages on the future glory of Israel. A feature of some Midrashim (e.g., nos. 4, 5d, e, and 7 below) is the halakic exordium which precedes the proems.

Among the more important Midrashim are: i. Mekhīta (Aram. "measure," i.e. "rule") best known as the name of a now imperfect halakic Midrash on Exod. xii.—xxiii. 19 (also xxxi. 12—17 and xxxv. 13). It represents the school of R. Ḥisdai Ishmael, is a useful source for old Haggada (especially on the narrative portions of Exodus), and is interesting for its variant readings of the Canonical text, e.g., Ugoïlius, Thes. Antiq. Sacr. iv. (Venice, 1744, with a poor Latin translation) by J. H. Weiss (Vienna, 1865) and M. Friedmann (ibid. 1870). German trans. by J. Winter and A. Wunsche Leipzig, 1909). See further J. Z. Lauterbach, Jev. Ency. viii. 444 seq.

ii. Siphra (Aram. "the book") or Torath Kohanim ("the law of the priests"), a commentary on Leviticus, mainly halakic, the text being a source for various maxims. (On Exod. xv. 17 seq., neighbourly love and abstinence from vengeance constitute, according to R. Aqiba, the great principle of the Torah.) It is useful for the interpretation of the Mishnah treatises Qoḏesh hayyim and Haggadah Latan (Lam.); for other information respecting the Midrashim, see E. Friedmann, "Leh. Breslau," 1884 seq., and the notable commentary of Samson (Samson) of Siences (Warsaw, 1860); see Jev. Ency. xi. 330 seq.

iii. Siphre (Aram. "the books"), an old composite collection of Halaka on Numbers, after R. Ishmael's school; and on Deut. after that of R. Aqiba, although the haggadic portions belong to the former. Latin in Ugoi. xv.; recent edition, with good introduction by R. Adler (Vienna, 1864); see Jev. Ency. xi. 332 seq.

The above works, although of 5th century origin, date in their present form, contain much older material, which was perhaps first redacted in the earlier part of the 2nd century, A.D. They are of

1 Cited by S. Schecter, Hastings, Dict. Bibl. v. 64.

2 See on this point, Jev. Ency. viii. 549 seq., 552, 576; Schetech, op. cit. p. 62; Schenkl, op. cit. p. 114 seq. We need not doubt that these verses were due to later reflexion on the part of Christians who had realized the inadequacy of the law.

3 See more fully Jew. Ency. viii. 555. Cf. for the structure, the hopeful concluding notes in the prophecies (e.g. Amos) and the discussion in the reading of the lesson from the prophets in Luke xiv. 17 seq. Acts xiii. 19 seq.

midshipman, officers. (d) the ed. is Germ. Abrahams also

vi. Midrash Rabbah (or Rabbath), a large collection of very diverse origin, probably not completed before the 13th century. It covers the Pentateuch (1st ed. Constantinople, 1512) and the Tanakh (vii. xii. pp. 67 seq.). It is based on the anonymous book "Bemidbar and many other Midrashim and excerpts from the old sources. See Jew. Ency. v. 560 seq. (f) Shemot ("names") Exod. i. i. R., a composite and incomplete work of 11th and 12th century date, but valuable nevertheless for its Tanakh and Midrash contents. (g) Num. vii. 50 seq. See the arrangement of Tanahim and excerpts from the old sources. See Jew. Ency. iv. 467 seq. (f) Shir ("song") R., or (after the opening words) Aggadath Hazith, a late compilation of aggadah on Canticles, illustrating the alephabetic interpretation of the song of Songs and Canticles, already in the exegesis of R. Aqba, cf. also 2 Esd. v. 24. 26, vii. 26. For this and other Mid. on this popular book, see Jew. Ency. vii. 556 seq. (f) Mid. Rabbah, a compilation including an exposition of 1 Chron. iv. 21—23, xi. 13-15 and interesting Messianic references. For this and similar Mid. or Ruth, see Jew. Ency. viii. 555, x. 577 seq. (f) Ekhah ("how") Rabbah, a compilation of about the 7th century on Lamations, from sources cited also in the Palestinian Talmud. Thirty-six proems precede the commentary. See Jew. Ency. v. 85 seq. (f) Mid. Koheloth or Koh. Rabbah, on Ecclesiastes; see Jew. Ency. viii. 559 seq. (f) Mid. Tanahim, on Job, dating, taking its name from a defunct predecessor, Rab Kahana. Although it goes back to early Haggada it has received later additions (as is shown by the technique of the proems). Edited by S. Buber (Lyck, 1866). (h) Midraschim (Leipzig, 1886); see Jew. Ency. viii. 559 seq. Not to be confused with this is—

vii. Piṣṭa ("section") or P. de Rab Kahana, contains 33 or 34 homilies (on the principal festivals), the first of which opens with a statement that Rab Kahana, the son of Jochanan (see Jochanan the elder), the successor, Rab Kahana. Although it goes back to early Haggada it has received later additions (as is shown by the technique of the proems). Edited by S. Buber (Lyck, 1866). (h) Midraschim (Leipzig, 1886); see Jew. Ency. viii. 559 seq. Not to be confused with this is—

vii. Piṣṭa Ḥabah.—A very similar but larger collection of 51 homilies, of which 28 have a halakic exordium prefixed to the Tanahim-proems, perhaps of 9th century. Edited by L. Böhm (Viena, 1880). Quite another and later work is the Pts. Zuta and Zuta b. Tobiah b. Eliezer of Mainz (trans. Ugelioni, vol. xxv. seq.; ed. Buber, 1880); see Jew. Ency. viii. 561 seq. With all these additions to the more prominent Midrashim mentioned above there are numerous self-contained works of greater or less interest. Some are connected with Old Testament books; e.g. Aggadath Bereishith, 83 homilies on Genesis, each in three parts connected with a section of the weekly pentateuch, and one from the Prophets, and a Psalm (ed. Buber, Cracow, 1902; see Jew. Ency. viii. 563); the Midrashim on the Psalms (Germ. trans., Venice, 1829 seq.). Others are more fanciful, e.g. Pirge or Baraitha de-Rabbah Eliezer, a fanciful narrative of events selected from the Pentateuch, &c.; the eschatology is interesting. Though associated by name with a well-known 1st century Rabbi, it is hardly earlier than the 8th (Latin trans., Vorstius, Leiden, 1639), see Jew. Ency. viii. 565 seq. Further, the Megillah Tannah ("roll of fasts"), an old source with a number of attractive fanciful legends, &c.; Megillah Antiquachos, on the martyrdom under Hadrian; Seder Omer Rabba, on biblical history from Adam to the rebellion of the Jews (Barcellona, 1602, ed. N. Schwab, Venice, 1829, &c.) is in reality a work of Jeralmeel," &c. Liturgical Midrash is illustrated by the Haggada shel Pesah, part of the ritual recited at the domestic service of the first Passover evening. In Midrashi Te'amim Hahor Al-Yehud, Hebrew words written "selected" or "chosen" are always rendered with Masoretic details, are haggadically treated. Finally Kallahub (q.v.) is exemplified in Othiyoth de R. Aqiba on the alphabet, and M. Talmud de R. Shalom, in which, indeed, such words as "King," "Chief Numbers," &c.; of some interest for its relation to the book of Jubilees.

ix. Of collections of Midrash the chief are (a) the Yalkut Shimeoni, which arranges the material according to the text of the Old Testament (extending over the whole of it), preserves much from sources that have since disappeared, and is valuable for the criticism of the text of the Midrash (recent ed. Wilna, 1898) translation of the Yalkut on Zechaviah by E. G. King (Cambridge, 1882; see further Jew. Ency. xii. 585 seq.). (b) Yal. ha-Mohri, perhaps later, covers only certain books, is useful for older sources and their criticism; portions have been edited by Spira (1843, on Isaiah); Buber (1899, on Joshua), see R. Grünbaum, in Da. Schelikow, 1895; D. Schiller-Szinessy, "the great," an extensive thesaurus, but later (quoting from H. Ezra, Maimonides, &c.; the arrangement is not so careful as in Yal. ha-Mohri). See further Jew. Ency. xii. 568 seq.

Of modern collections special mention may be made of A. Jellinek's Bet ha-Midrasch (Leipzig, 1853), and A. Wünsche's valuable translations; to these already mentioned must be added his A. Jellinek, "Kanfas, Lamont's excerpts of a more miscellaneous character (Leipzig, 1907 seq.)

Besides dictionary articles on this subject (S. Schiller-Szinessy, Enzyk. Brit., 9th ed.; H. L. Strack, Real-Ency. J. Theol. u. Kirche, 3rd ed.), a special work on the Talmud is the famous Talmodimschene, by D. Hoffmann, Zur Einleitung in die halachischen Midrashen (Berlin, 1888), and the great work on Zunz, Die gottesdienstliche Vermittlung der Juden, 2nd ed., by N. Brüll (Frankfort on Main, 1898). These, as also the citations in the course of this article, give fuller information. (See further TALMUD.) (S. A. C.)

MIDSHIPMAN, the title in the British and American navies of the "young gentlemen" who are serving in order to qualify themselves to hold a commission as lieutenant. The English midshipman was originally a petty officer, one of the crew under the immediate orders of the boatswain. After the restoration of King Charles II., in 1660, the king and his brother, James Duke of York, lord high admiral, decided to train officers for the sea service. They therefore decided to send a volunteer to each ship of a squadron in commission, with a "letter of service," which instructed the admirals and captains that the bearer was to be shown "such kindness as you shall judge fit for a gentleman, both in accommodating him in your ship and in furthering his improvement." He was to receive the pay of a midshipman, and one midshipman less was to be borne in the ship. Until 1729 the young gentlemen who entered the British navy were known as "king's letter boys." In that year the system was altered. A school, known as the national academy, was founded at Portsmouth in which forty lads were to be trained for the sea service. In 1773 the school, having proved unsatisfactory, was reorganized and a number of boys of trained there increased from forty to seventy. In 1806 it was again reorganized, under the name of the naval college, and was finally suppressed in 1837, when the practice of training the boys under instructors in the ships was introduced. A special school was re-established in 1837, and was finally placed in the Brit. In the meantime the number of midshipmen had increased far beyond one for a ship. A line of midshipmen in the 1840's was expected to number forty, and the title had come to be confined entirely to those who were being trained as officers. The immense majority of officers of the British navy never passed through the academy or the college. They entered the ships directly as "captains' servants" or "volunteers," and were rated midshipman, if there was a vacancy, at the age of fifteen. As they were expected to learn navigation, they were instructed by the master, and at the age of seventeen were supposed to be qualified to be masters' mates. To-day the midshipman is the officer of the British and American navies who has passed through the
preliminary schools and has been appointed to a ship. The French equivalent is aspirant, and other European navies use that medium.

MIDSOMER NORTON, an urban district in the northern parliamentary division of Somersetshire, England, 12 m. S.S.W. of Bath, on the Somerset & Dorset and the Great Western railways. Pop. (1901), 5889. The town is pleasantly situated in a hilly district, between two branches of the small river Somer. The church of St John the Baptist, principally Perpendicular, has in its tower three bells presented by Charles II. Both this town and the adjacent districts of Radstock (pop. 3355) have considerable trade in coal, while metals, oil, and minerals are worked in the vicinity. The coalfield extends north-westward towards Bristol, and is of great importance to the manufactures of that city.

MIDWIFE (Mid. Eng. midwif, mydylw or mederif, from preposition mid, with, and wife, i.e. woman, in the sense of one who is with the mother, or from adjective mid, one who is the means of delivering the mother, a woman who assists other women in childbirth.) As a class, midwives were recognized in Egypt in the time of the Jewish captivities. They continued to prevail in the continent of Europe until the middle of the 16th century, as it is to-day in the East, that women should be attended in confinement only by those of their own sex. From that period more attention was given to the practice of midwifery by the medical profession (see Obstetrics), while in continental Europe, towards the close of the 17th century, special schools were instituted for the proper training of midwives. But it was not until well on in the 19th century that any supervision or regulation was imposed on those who acted as midwives. Now in practically every European country midwives are under strict state control, they are required to undergo a course of thorough training, and their practice is carefully regulated by legislation.

In France midwives (sages femmes) are divided into a first and a second class. Those qualifying for both classes go through a two years' course of training and are examined both in the theory and practice of midwifery, as well as in anatomy, physiology and pathology. A midwife of the first class has a superior status and can practise in any part of France, while those of the second class are restricted in their practice to the department for which the certificate is issued. Their qualifications allow them also to vaccinate and to prescribe certain antiseptic preparations. They are not allowed to use instruments and must call a doctor in matters of serious nature, and to a central officer. In Spain midwives are allowed to practise on the result of an examination after studies covering at least four half-years. The direction is given by the public institutions. In Germany midwives are appointed, recognized and authorized by the state. They can conduct confinements independently and without the aid of a medical man. They must be provided with a certificate from the police authorities, and must reside in special districts assigned to them by the authorities. In Austria midwives before they are allowed to practice must pass a strict examination, after having followed a six months' course at one of the state schools of midwifery. They are subject to elaborate "instructions for midwives" issued from time to time by the ministry of the interior. In Italy a midwife must pass an examination and obtain a diploma from a recognized authority; but in order to obviate the difficulty which the poorer classes in the smaller communities would find in obtaining properly-authorized midwives, a certificate of permission to the maternity of a certain number who have practised without the sanction of the law satisfactorily during a term of five years. These certificates are distributed by the prefect. In Russia matters pertaining to the appointment, transfer, dismissal and pay of midwives are under the charge of the medical department of the ministry of the interior. In each town of a province or region there is stationed one senior midwife and a number of junior midwives, the number of districts in the province. The examination of midwives is by the issue of a certificate of competency is carried out by the Medico-Chirurgical Academy and certain of the universities. A duly-licensed midwife, on presenting herself, is at once permitted to enter from one district to another class to which she may have belonged. The general code of Russian laws lays down extensive rules for the carrying out of the duties of midwives. In Norway all midwives are licensed after examination and have to be registered and control and supervision of the board. Provision is made for infrin and aged midwives. They are usually paid by the parish, but also receive fees according to the means of the person attended. In Sweden a certificate of competency and of having passed an examination does not give a midwife a right to practise until a note has been made on the certificate that the oath of office has been duly taken. All midwives are under the control of the board of health. If a midwife takes up her practice from one place to another, she must announce the fact within a month to the nearest appointed doctor and exhibit her certificate. In towns a midwife must put up a notice board in order to show her knowledge. The conditions of a licence include the permission of the midwifery is almost entirely in the hands of women. In Holland a certain number of candidates are given free training by the state in return for their practising midwifery in scattered counties. In the United States have also passed laws for the registration of midwives.

In England alone there was no regulation of any kind so late as 1819. A midwife ignorant and untrained, could describe herself as a midwife and practise for gain. Several societies made continuous efforts towards the close of the 19th century to obtain legislation. A select committee was appointed in 1877, to report on the evils of midwifery, and it was not successful until 1902. The Midwives Act 1902 forbids any woman after the 1st of April 1905 to call herself a midwife without a certificate, and this has been extended as a midwife's term of 1910. Existing midwives (those who have certificates in midwifery from certain recognized institutions, or produced satisfactory evidence at the passing of the act they could have obtained one before) were allowed to continue as midwives, and bore good characters) were allowed to claim certificates within two years from the 1st of April 1903. The act created a central midwives' board, whose duties are, inter alia, to regulate the issue of certificates and the conditions of admission to the roll of midwives; to regulate the course of training and conduct of examinations; to regulate, supervise and restrict within due limits the practice of midwives, also to make a roll of duly certified midwives; to remove from the roll the name of any midwife who disobeys the rules and regulations laid down from time to time; to issue and cancel certificates, &c. There is an appeal to the High Court of Justice against the regulation of the roll. The act does not apply to Scotland.

MIERES, a town of northern Spain, in the province of Oviedo, 12 m. by rail S.E. of Oviedo, on the river Cudal, a tributary of the Nalon. Pop. (1900), 18,083. Mieres is the chief town of a mountainous, fertile and well-watered region in which coal, iron, and copper are extensively mined and sulphur and cinnamon are obtained in smaller quantities. The town contains large iron foundries and chemical works, and has an active trade in fruit, cider, timber and live stock.

MIEREVELT (Miereveld, or Mierevelt), Michiel Jansz van (1567-1641), Dutch painter, was born at Delft, the son of a goldsmith, who apprenticed him to the copperplate engraver Jacob Verly. He subsequently became a pupil of Willem Willemz and Augusten of Delft, until Anthonie van Montfoort (Blocklandt), who had seen and admired two of Mierevelt's early engravings, "Christ and the Samaritan" and "Judith and Holofernes," invited him to enter his school at Utrecht. Devoting himself first to still life, he eventually took up portraiture, in which he achieved such success that the many commissions entrusted to him necessitated the employment of numerous assistants, by whom hundreds of portraits were turned out in factory fashion. The works that can with certainty be ascribed to his own brush are remarkable for their sincerity, severe drawing and harmonious colour, but comparatively few of the two thousand or more portraits that bear
his name are wholly his own handiwork. He settled down in his native town, but went frequently to The Hague, where he entered the gild of St Luke in 1625. So great was his reputation that he was patronized by royalty in many countries and acquired great wealth. The king of Sweden and the count palatine of Neuburg presented him with golden chains, Archduke Albrecht gave him a pension, and Charles I. vainly endeavoured to induce him to visit the English court. Though Mierevelt is chiefly known as a portrait painter, he also executed some mythological pieces of minor importance. Many of his portraits have been reproduced in line by the leading Dutch engravers of his time. He died at Delft on the 27th of June 1641.

The Rijks Museum in Amsterdam has the richest collection of Mierevelt’s works, chief of them being the portraits of William, Philip William, Maurice, and Frederick Henry of Orange, and of the count palatine Frederick V. At The Hague Museum are the portraits of four princes of the house of Orange, of Frederick V., king of Bohemia, and of Louise de Coligny as a widow. Other portraits by him are at nearly all the leading continental galleries, notably at Brunswick (1), Gotha (2), Schwerin (3), Munich (2), Paris (Louvre, 3), Dresden (4), Berlin (2), and Darmstadt (3). The town hall of Delft also has numerous examples of his work.

Many of his pupils and assistants rose to fame. The most gifted of them were Paulus Moreelse and Jan van Ravesteyn. His sons Pieter (1596–1623) and Jan (d. 1633), and his son-in-law Willem Jacobz Delf, probably painted many of the pictures which are ascribed to his name. His portrait was painted by van Dyck and engraved by Delff.

MIERIS, the name of a family of artists who practised painting at Leiden for three generations in the 17th and 18th centuries.

1. FRANS VAN MIERIS, the elder (? 1635–1681), son of Jan Van Miereis, a goldsmith and diamond setter, was born, according to Houbraken, at Leiden on the 16th of April 1635, and died there on the 12th of March 1681. His father wished to train him to his own business, but Frans preferred drawing to chasing, and took service with Abraham Torenvliet, a glazier who kept a school of design. In his father’s shop he became familiar with the manner of drawing of people of distinction. His eye was fascinated in turn by the sheen of jewelry and stained glass; and, though he soon gave up the teaching of Torenvliet for that of Gerard Douw and Abraham van den Tempel, he acquired a manner which had more of the finish of the exquisites of the Dutch school than of the breadth of the disciples of Rembrandt. It should be borne in mind that he seldom chose panels of which the size exceeded 12 to 15 in., and whenever his name is attached to a picture above that size we may surely assign it to his son Willem or to some other imitator. Unlike Gerard Douw when he first left Rembrandt, or Jan Steen when he started on an independent career, Mieris never ventured to design figures as large as life. Characteristic of his art in its minute proportions is a shiny brightness and metallic polish. The subjects which he treated best are those in which he illustrated the habits or actions of the wealthier classes; but he sometimes succeeded in homely incidents and in portrait, and not unfrequently he ventured on allegory. He repeatedly painted the satin skirt which Ter Borch brought into fashion, and he often rivalled Ter Borch in the faithful rendering of rich and highly-coloured woven tissues. But he remained behind Ter Borch and Metsu, because he had not their delicate perception of harmony or their charming mellowness of touch and tint, and he fell behind Gerard Douw, because he was hard and had not his feeling for effect by concentrated light and shade. In the form of his composition, which sometimes represents the framework of a window enlivened with greenery, and adorned with bas-reliefs within which figures are seen to the waist, his model is certainly Gerard Douw.

It is a question whether Houbraken has truly recorded this master’s birthday. One of his best-known pieces, a party of ladies and gentlemen at an oyster luncheon, in the Hermitage at St Petersburg, bears the date of 1629. Celebrated alike for composition and finish, it would prove that Mieris had reached his prime at the age of fifteen. Another beautiful example, the “Doctor Feeding a Lady’s Pulse” in the gallery of Vienna, is dated 1656; and Waagen, in one of his critical essays, justly observes that it is a remarkable production for a youth of twenty-one. In 1657 Mieris was married at Leiden in the presence of Jan Potheuck, a painter, and this is the earliest written record of his existence on which we can implicitly rely. Of the numerous panels by Mieris, twenty-nine at least are dated—the latest being an allegory, long in the Rubel collection at Cologne, illustrating the Latin proverb, he who considereth the kindred vices of drinking, smoking and dicing, in the year 1680. Mieris had numerous and distinguished patrons. He received valuable commissions from Archduke Loopold, the elector-palatine, and Cosimo III., grand-duke of Tuscany. His practice was large and lucrative, but never engendered in him either carelessness or neglect. If there be a difference between the painter’s earlier and later work, it is that the former was clearer and more delicate in flesh, whilst the latter was often darker and more vivid in the shadows. When he died his clients naturally went over to his son Willem, who in turn bequeathed his painting-room to his son Frans. But neither Willem nor Frans the younger equalled Frans the elder.

2. WILLEM VAN MIERIS (1662–1747), son of Frans. His works are extremely numerous, being partly imitations of the paternal subjects, or mythological episodes, which Frans habitually avoided. In no case did he come near the excellence of his sire.

3. FRANS VAN MIERIS, the younger (1689–1763), also lived on the traditions of his grandfather’s studio.

The pictures of all the generations of the Mieris family were successfully imitated by A. D. Snaphaan, who lived at Leipzig and was patronized by the court of Anhalt-Dessau. To those who would study his deceptive form of art a visit to the collection of Woritz near Dessau may afford instruction.

MIFFLIN, THOMAS (1744–1806), American soldier and politician, was born in Philadelphia, Pennsylvania, on the 10th of January 1744, of Quaker parentage. He graduated at the college of Philadelphia (now the university of Pennsylvania) in 1760. As a member of the Pennsylvania house of representatives in 1772–1775, he was an ardent Whig, and in 1774 was a member of the first Continental Congress. After the outbreak of the War of Independence he devoted himself chiefly to the enlisting and drilling of troops, and was chosen major of a regiment. In June 1775 he entered the continental service as Washington’s first aide-de-camp, and in August was chosen quartermaster-general. He became a brigadier-general in May 1776 and a major-general in February 1777. On the 4th of June 1776 he was succeeded as quartermaster-general by Stephen Moylan. Moylan, however, proved incompetent, and Mifflin resumed the office on the 1st of October. In the autumn of 1777 Mifflin was a leader in the obscure movement known as the Conway Cabal, the object of which was to replace Washington by General Horatio Gates. On the ground of ill health Mifflin tendered his resignation on the 8th of October, and on the 7th of November Congress accepted his resignation as quartermaster-general, but continued him in rank as major-general without pay. On the same day he was appointed a member of the new board of war, and on the following day was asked to continue as quartermaster-general until his successor should be appointed. On the 21st of November he urged before the old board of war and ordinance that Gates should be made president of the new board of war “from a conviction that his military skill would suggest reorganizations in the different departments of the army essential to good discipline, order and economy, and that his character and popularity in the army would facilitate the execution of such reorganizations when adopted by Congress.” The attacks on Washington failed, and in March 1778 Mifflin was finally superseded as quartermaster-general by General Nathanael Greene. In October of the same year he was removed from the board of war. The sufferings of the troops at Valley Forge having been charged to his mismanagement as quarter-
MIGNARD, Pierre (1610-1665), called—to distinguish him from his brother Nicolas—Le Romain, French painter, was born at Troyes in 1610, and came of a family of artists. In 1630 he left the studio of Simon Vouet for Italy, where he spent twenty-two years, and made a reputation which brought him a summons to Paris. Successful with his portraits of the king, and in favour with the court, Mignard pitted himself against Le Brun, declined to enter the Academy of which he was the head, and made himself the centre of opposition to its authority. The history of this struggle is most important, because it was identical, as long as it lasted, with that between the old guilds of France and the new body which Colbert, for political reasons, was determined to support. Shut out, in spite of the deserved success of his decorations of the cupola of Val de Grace (1664), from any great share in those public works the control of which was the attribute of the new Academy, Mignard was chiefly active in portraiture. Turenne, Molière, Bossuet, Maintenon (Louvre), La Vallière, Sévigné, Montespan, Descartes (Castle Howard), all the beauties and celebrities of his day, sat to him. His readiness and skill, his happy instinct for grace of arrangement, atoned for want of originality and real power. With the death of Le Brun (1690) the situation changed; Mignard deserted his allies, and succeeded to all the posts held by his opponent. These late honours he did not long enjoy; in 1695 he died whilst about to commence work on the cupola of the Invalides. His best compositions have been engraved by Audran, Edelinck, Masson, Pouilly and others.

MIGNARD, Jacques Paul (1800-1875), French priest and publisher, was born at St Flour, Cantal, on the 25th of October 1800. He studied theology at Orleans, was ordained priest in 1824 and placed in charge of the parish of Puisieux, in the diocese of Orleans. In 1833 he went to Paris, and started L'Univers religieux, which afterwards became Louis Veuillot's ultramontane organ. On severing his connexion with the paper three years later, he opened at Petit Montrouge, near Paris, the great publishing house which brought out in rapid succession numerous religious works at popular prices. The best known of these are: Scripturae sacrae cursus completus, et Theologiae cursus (each in 28 vols., 1840-1845); Collection des auteurs sacrés (100 vols., 1846-1848); Encyclopédie théologique (171 vols., 1844-1860); Patrologiae cursus completus, Latin series in 15 vols. (1844-1853); 2d edition, 1878 seq.; Greek series, first published in 1836-1855 vols., 1879 seq., with Greek text and Latin translation (165 vols., 1857-1860). Unfortunately these editions, brought out in great haste and often edited by superficial scholars, do not come up to the requirements of modern criticism. By far the most noteworthy is the Patrology, which was superseded by the learned Benedict J. B. Pitra. Its vast scope leaves it still unique and valuable, where other editions of special works do not exist. The indices in 3 vols. are arranged so that one may easily find any reference in the patristic writings. In February 1868 a great fire destroyed the whole of Migne's printing premises, but he established a new house in Paris, which was purchased in 1876 by the publishers Garnier Frères, who still own all the works brought out by Migne. He died in Paris on the 24th of October 1875. For a more complete account of Migne's life, see the article in the Catholic Encyclopedia (New York, 1906 seq.).

MIGNET, François Auguste Alexis (1796-1854), French historian, was born at Aix in Provence on the 8th of May 1796, and died at Paris on the 24th of March 1884. His father, a Vendean by birth, was an ordinary locksmith, who enthusiastically accepted the principles of the French Revolution and roused in his son the same love for liberal ideas. François had brilliant successes when studying at Avignon in the lyceé where he was afterwards professor (1815); he returned to Aix under the legal law, and in the spirit of the Revolution would have ensured his success had he not preferred the career of an historian. His abilities were shown in an Essai de Charles VII., which was crowned by the Académie de Nîmes in 1820, and a memoir on Les Institutions de Saint Louis, which in 1821 was crowned by the Académie des Inscriptions et Belles Lettres. He then went to Paris, where he was soon joined by his friend and compatriot, Adolphe Thiers, the future president of the French republic. He was introduced by J. A. Manuel, formerly a member of the Convention, to the Liberal paper, Courrier français, where he became a member of the staff which carried on a fierce pen-and-ink warfare against the Restoration. He acquired his knowledge of the men and intrigues of the Napoleonic epoch from Talleyrand. He wrote a Histoire de la révolution française (1824) in support of the Liberal cause. It was an enlarged sketch, prepared in four months, in which more stress was laid on fundamental theories than on the facts, which are more rigidly linked together than their historical sequence warrants. In 1830 he founded the National with Thiers and Armand Carrel, and signed the journalistic manifesto, the Ordonnances de juillet, but he refused to accept his share of the spoil after his party had won. He was satisfied with the modest position of director of the archives at the Foreign Office, where he stayed till the revolution of 1848, when he was dismissed, and retired permanently into private life. He had been elected a member of the Académie des Sciences Morales et Politiques, re-established in 1832, and in 1837 was made the permanent secretary; he was also elected a member of the Académie Française in 1836, and sought no further honours. He was well known in fashionable circles, where his witty conversation and his pleasant manners made him a favourite. The greater part of his time was, however, given to study and to his academic duties. Eulogies on his deceased fellow-members, the Academy reports on its work and on the prizes awarded by it, which it was part of Mignet's duty as secretary to draw up, were literary fragments thoroughly appreciated by connoisseurs. They were collected in Mignet's Notices et portraits. He worked slowly when in his study, and willingly lingered over research. With the exception of his description of the French Revolution, which was chiefly a political manifesto, all his early works refer to the middle ages—De La fédéralité, des institutions de Saint Louis et de l'influence de la législation de ce prince (1822); La Germanie au viii et au ix siècle, sa conversion au christianisme, et son introduction dans la société civile de l'Europe occidentale (1834); Essai sur la formation territoriale et politique de la France depuis la fin du xi siècle jusqu'à la fin du xve (1836); all of these are rough sketches showing only the outlines of the subject. His most noted works are devoted to modern history. For a long time he had been taken up with a history of the Reformation, but only one part of it, dealing with the Reformation at Geneva, has been published. His Histoire de Marie Stuart (2 vols., 1852)
MIGNON.—MIGRATION

is well worth reading; the author made liberal use of some important unpublished documents, taken for the greater part from the archives of Simancas. He devoted some volumes to a history of Spain, which had a well-deserved success—

Charles Quint, son abdication, son séjour, et sa mort au monastère de Yuste (1843); Antonio Perez et Philippe II. (1843); and 

Histoire de la réalité de François I. et de Charles Quint (1873).

At the same time he had been commissioned to publish the diplomatic acts relating to the War of the Spanish Succession for the centre of the year and to the whole group of documents of these Négociations were published (1835-1842), and the work not go further, but the peace of Nijmegen; but the introduction is celebrated, and Mignon reprinted its in his Mélanges historiques.

See the eulogy of Mignet by Victor Duruy, delivered on entering the Académie Française on the 18th of June 1885, and the notice by Jules Simon, read before the Académie des Sciences Morales et Politiques on the 7th of November 1885.

MIGNON, ABRAHAM (1649-1697), Dutch painter, was born at Frankfort. His father, a merchant, placed him under the still-life painter Jacob Merrel, by whom he was taken to Holland about 1660. He then worked under de Heem at Utrecht, where in 1675 he married the daughter of the painter Cornelis Willaerts. Sibylle Merian (1647-1717), daughter of the engraver Matthew Merian, became his pupil and achieved distinction as a flower painter. He died at Wetzlar. Mignon devoted himself almost exclusively to flowers, fruit, birds and other "still life," though at times he also attempted portraiture. His flower pieces are marked by careful finish and delicate handling. His favourite scheme was to introduce red or white roses in the centre of the frame and to leave the whole group of flowers against a dark background. Nowhere can his work be seen to better advantage than at the Dresden Gallery, which contains fifteen of his paintings, twelve of which are signed. Six of his pictures are at the Louvre, four at the Hermitage, and other examples are to be found at the museums of Amsterdam, The Hague, Rotterdam, Brussels, Munich, Karlsruhe, Brunswick, Cassel, Schwerin, Copenhagen and Turin.

MIGNONETTE, or MIGNONNETTE (i.e. "little darling"), the name given to a popular garden flower, the Reseda odorata of botanists, a "fragrant weed," as Cooper calls it, highly esteemed for its delicate but delicious perfume. The mignonette is generally regarded as being of annual duration, and is a plant of diffuse decumbent twiggy habit, scarcely reaching a foot in height, clothed with blunter lanceolate entire or three-lobed leaves, and bearing longish spikes—technically racemes—of rather insignificant flowers at the ends of the numerous branches and branchlets. The plant thus naturally assumes the form of a low dense mass of soft green foliage studded over freely with the racemes of flowers, the latter unobtrusive and likely to be overlooked until their diffused fragrance compels attention. It is probably a native of North Africa and was sent to England from Paris in 1742; and ten years later it appears to have been sent from Leiden to Philip Miller at Chelsea. Though originally a slender and rather straggling plant, there are now some improved garden varieties in which the growth is more compact and vigorous, and the inflorescence holder, though the odour is perhaps less penetratin. The small six-petalled flowers are somewhat curious in structure: the two upper petals are larger, concave, and furnished at the back with a tuft of club-shaped filaments, which gives the effect of an insect being deeply incised, while the two lowest petals are much smaller and uniedivided; the most conspicuous part consists of the anthers, which are numerous and of a brownish red, giving the tone of colour to the inflorescence. In the varieties named Golden Queen and Golden Machtich the anthers have a decided tint of orange-yellow, which imparts a brighter golden hue to the plants when in blossom. A handsome prolific or double-flowered variety has also been obtained, which is a very useful decorative plant, though only to be propagated by cuttings; the double white flowers grow in large massive panicles (proliferous racemes), and are equally fragrant with those of the ordinary forms.

What is called tree mignonette in gardens is due to the skill of the cultivator. Though practically a British annual, as already noted, since it flowers abundantly the first season, and is utterly destroyed by the autumnal frosts, and though recorded as being annual in its native habitat, yet it is found in the Flora Atlantica of the mignonette, like many other plants treated in England as annuals, will continue to grow on if kept in a suitable temperature. Moreover, the life of certain plants of this so-called character may be prolonged into a second season if their flowering tips are persistently prevented. In applying these facts to the proper tree mignonette, the gardener grows on the young plants under glass and prevents their flowering by nipping off the blooming tips of the shoots, so that they continue their vegetative growth into the second season. The young plants are at first supported in an erect position, the branchlets being so arranged as to secure clean upright stems, and then at the height of one or two feet on, as may be desired, a head of branches is encouraged to develop itself. In this way very large plants can be produced.

For ordinary purposes, however, other plans are adopted. In the open borders of the garden flower mignonette is usually sown in spring, and in great part takes care of itself; but being a favourite fragmentary collection and on account of its fragrance a welcome inmate of town conservatories. It is also very extensively grown, as a pot plant, and for market purposes with this object it is sown in pots in the autumn, and thinned out to give the plants room for growth, since it is grown from transplants and not specially grown in pots protected from frost, and marketed when just arriving at the blooming stage. In this way hundreds of the softest pots of blooming mignonette are raised and disposed of year by year.

In classifying the odours given off by plants Rimmel ranks the mignonette in the class of which he makes the violet the type; and Fée adopts the same view, referring it to his class of "isomotes" along with the violet and wallflower.

The genus Reseda contains about fifty species, natives of Europe and Asia. R. luteola, commonly called dyer's-weed and weld, yields a valuable yellow dye. R. alba is a fine biennial about 2 ft. high, with erect spikes of white flowers.

MIGNONS, LES. In a general sense the French word mignon means "favourite," but the people of Paris used it in a special sense to designate the favourites of Henry III. of France, frivolous and fashionable young men, to whom public malignity attributed dissolute morals. According to the contemporary chronicler Pierre de l'Estoile, they made themselves "exceedingly odious, as much by their foolish and haughty demeanour, as by their effeminate and unmodest dress, but above all by the immense gifts the king made to them in order to have stirred up the ill will of the Parisians against them. From 1576 the mignons were attacked by popular opinion, and historians accredited without proof the scandalous stories of the time. The best known of the mignons were the dukes of Joyeuse and of Épernon.

MIGNOT, CLAUDINE FRANÇOISE [commonly called MARIE] (c. 1617-1711), French adventuress, was born near Grenoble, at Meylan. At the age of sixteen she attracted the notice of the secretary of Pierre des Portes d'Amblérieux, treasurer of the province of Dauphiny, and Amblérieux promised to promote their marriage. He married the girl himself, however, and left her his fortune. His will was disputed by his family, and Claudine went to Paris in 1653 to secure its fulfilment. She sought the protection of François de l'Hôpital, marshal of France, then a man of seventy-five. He married her within a week of their first meeting, and after seven years of marriage died leaving her part of his estate. By a third and morganatic marriage in 1672 with John Casimir, ex-king of Poland, a few weeks before his death, she received a third fortune. Immediately after marriage with Amblérieux she had begun to educate herself, and her wealth and talents assured her a welcome in Paris. She retired in her old age to a Carmelite convent in the city, where she died on the 30th of November 1711.

Her history, very much modified, was the subject of a play by Bayard and Paul Duport, Marie Mignon (1829).

MIGRATION. Under this title will be considered movements of men with intention of changing their residence or domicile. Such migration (Lat. migrare) may be either external—that is, from one country to another, including emigration from mother country to colony; or it may be internal—that is, within
the limits of a single country. Under external migration are comprised emigration and immigration, denoting simply direction from and to. The emigrants are at the same time the immigrants; that is, the material of the movement is the same, but the effect upon the country giving up and the country receiving the migrant requires separate treatment. Hence it is proper to separate emigration from immigration. Temporary migration, or travel for purposes of business, enterprise or pleasure, will be considered only incidentally, and because in some cases it is difficult to distinguish between such movements and permanent migration.

Migration in general may be described as a natural function of social development. It has taken place at all times and in almost every variety of circumstances. It has been tribal, national, class and individual. Its causes have been political, economic, religious, or mere love of adventure. Its causes and results are fundamental for the study of ethnology (formation and mixture of races), of political and social history (formation of states and survival of institutions), and of political economy (mobility of labour and utilization of productive forces). Under the form of conquest, families and entire peoples have been moved from one region to another. The form of colonization has been: 1. The fall of the Roman Empire; 2. The transformation of the world (e.g. the colonization of America); under free initiative it is the most powerful factor in social adjustment (e.g. the growth of urban population). It must suffice here to indicate the character of the principal movements in the past, and then describe certain aspects of modern migration. The early movements may be grouped as follows: (a) Prehistoric migrations. Among savage and nomadic nations the whole tribe often moves into new territory, either occupying it for the first time or exterminating or driving out the indigenous inhabitants. We have only vague knowledge of these early movements, laboriously gleaned from archaeology, anthropology and philology. The cause has been commonly said to be the pressure of population on the food-supply. A more probable explanation is the love of booty and the desire of the stronger to take possession of the lands of the weaker. (b) Greek and Roman colonization. Both of these ancient civilizations extended their influence through migration of individual families and the planting of colonies. The motive seems to have been primarily commercial—that is, the love of gain. It may have been partly a sort of "swarming" process, caused by pressure of population at home. In some cases it had a political motive, as the planting of military colonies or providing new homes for the proletariat. The consequences were of course momentous. (c) The German Conquest. Beginning about the 5th century, the Roman empire was overthrown by German tribes from the north of the river Danube and east of the river Rhine. This Völkerwanderung, as it is called by German historians, again transformed the face of Europe, resulting in the establishment of independent kingdoms and a great mixture of races and institutions. It was in accordance with the building-out of the feudal system. The conquered in many cases could be left as serfs and tillers of the soil, while the conquerors seized the higher positions of administration and power. (d) The later middle ages saw many minor migratory movements, such as those accompanying the crusades, the pushing of German colonization among the Slavs, and the introduction of Flemish weavers into England. The religious reformation caused a considerable amount of emigration, culminating in the expulsion of the Huguenots from France. (e) The period of discovery and colonization opened up a new era for migration. The first expeditions were for adventure and booty, especially the discovery of gold and silver. Then came the establishment of commercial posts or factories for the purposes of trade. Finally came colonization proper—that is, the settlement of new countries by Europeans intending to remain there permanently, but still retaining their connexion with the mother country. This meant the opening up of the world to commerce and the extension of European civilization to vast areas formerly peopled by savages or half-civilized peoples. It meant a great outlet for the spirit of enterprise and adventure, relief from over-population, an enormous increase in wealth and power, and a struggle for supremacy among the nations of Europe. Colonization and colonial policy excited immense attention in Europe; and this extended into the 19th century (cf. E. G. Wakefield's plans for colonization, and the various colonization societies of modern times). The colonial policy proper was broken down by the revolt of the North American colonies from Great Britain, and later of Mexico and Central and South America from Spain. (f) The movement of population, however, has continued under the form of emigration. This movement is characterized firstly by its magnitude; secondly, by the fact that the emigrant changes his political allegiance, for by far the greater part of modern emigration is to independent countries, and even where it is to colonies the colonies are largely self-governing and self-regarding; and thirdly, it is a movement of individuals seeking their own good, without state direction or aid. This is 20th-century emigration, differing from all preceding forms and having an importance of its own.

Statistics of Emigration.—The direction of the modern movement is from Europe to America, Australia and South Africa, as shown in the following table:

**Emigration from Certain States of Europe, 1850-1905.**

1 The figures relate only to the emigrants of each nationality emigrating from their own country to countries outside of Europe.
2 Exclusive of emigrants to Spanish colonies.
3 Russian emigrants from German ports.
MIGRATION

Since 1820 over twenty million persons have emigrated from Europe to countries beyond the sea. The greater part of this emigration has been to the United States of North America. The history of emigration is well shown in the following table of emigration from Great Britain and Ireland. Down to 1853 the figures include all emigrants from British ports; after 1853 emigrants of British and Irish origin only.

Emigration from Great Britain and Ireland, 1815-1905.

Total | 23,116,501 |

Prior to 1820 there was no official record of immigration, but it is estimated that the total number of immigrants from the close of the Revolutionary War was 250,000. During the decade from 1820 to 1830 the movement was very moderate. From 1830 to 1840 it steadily increased, but never reached 100,000 per annum. In 1846 came the Irish potato famine, and an enormous emigration began, followed by a very large German emigration from similar causes. The Civil War of the United States interrupted the movement, but it was speedily resumed on an enlarged scale owing especially to the improved means of ocean transportation. It culminated in the decade 1880-1890, and declined after the commercial crisis of 1893. Later there was another increase.

The relative movement of nationalities is best presented by the statistics of the United States. The nationality (country of origin of immigrants coming to the United States, 1871-1895) is shown in the following table:

A very important transformation has taken place in the proportionate number coming from different countries during the last half of the 19th century. At first the Irish and Germans were most prominent. Of later years, the Italians, Czechs, Hungarians and Russians were, as will be seen from the following table, numerously represented.

Nationality of Immigrants to the United States, 1901-1905.

</tr>
</tbody>
</table>

Occupation.—The immigrants are for the most part unskilled labourers. The statistics for the United States show the following figures for the years 1881-1890:

<table>
<thead>
<tr>
<th>Occupation</th>
<th>Number</th>
</tr>
</thead>
<tbody>
<tr>
<td>Professional</td>
<td>25,257</td>
</tr>
<tr>
<td>Skilled</td>
<td>514,552</td>
</tr>
<tr>
<td>Miscellaneous</td>
<td>1,333,327</td>
</tr>
<tr>
<td>None stated</td>
<td>78,527</td>
</tr>
<tr>
<td>Without occupation</td>
<td>759,450</td>
</tr>
</tbody>
</table>

Total                  | 3,205,911| 2,040,702| 5,246,613|

The "without occupation" are mostly women and children. The "miscellaneous" are day labourers. It is probable that about 20% of the adult males are "skilled."

Immigration to Other Countries.—In no other country is immigration conducted on so important a scale as in the United States. The statistics are very imperfect. The main figures have already been given in the table of emigration. Australia has an annual immigration of about 50,000, mostly of British origin, and a very heavy emigration, which sometimes exceeds the immigration in certain of the states. The immigration to Canada for the year 1905 was put down as 146,266, but a portion of these were Canadians returning. In the United States, Brazil has had a large immigration (in 1895 equal to 160,524, but in 1904 only 12,447). The Argentine is credited with an immigration in 1905 of 177,117, and Uruguay with an immigration of 1905 of 64,147. In all the South American immigration the countries principally represented are those of Southern Europe, especially Italy. The majority of the immigrants are adult males and farm labourers.

Balance of Emigration and Immigration.—Even in the case of emigration from Europe to countries beyond the seas there is some return movement. Emigrants who have been successful in business return in order to end their days in the old country. Those who have not succeeded return in order to earn a living by friends and relatives, or simply for home-sickness. Thus, for Great Britain and Ireland, while the emigration of persons of British and Irish origin was, in 1905, 262,077, the immigration of persons of the same category amounted to 122,712, leaving a net emigration of only 139,265. In the United States 'statistics we cannot distinguish in the outgoing passenger movement emigrants from other persons. But if for a period of years we take the total inward passenger movement and subtract the number of outward passenger movement, it is obvious that we have the net immigration. By this method we arrive at the conclusion that while the gross immigration during the five years 1901-1905 was 3,883,676, the net immigration was only 1,779,076, showing an outward movement of 2,104,600, or about 7-12% of the total number of immigrants.

Temporary Emigration.—In many European countries there is not only emigration beyond seas, but a very considerable movement to neighbouring countries in search of work and generally with the intention of returning. Thus in Italy, the "permanent" emigration (i.e. to countries beyond seas) numbered, in 1905, 447,083; the "temporary" emigration to European or Mediterranean countries amounted to 279,428. This temporary emigration is strongest in the spring and consists principally of adult males (agriculturists, farm and day labourers, bricklayers and masons) in search of work. It resembles somewhat the movement of Irish labourers into Great Britain at harvest times. It is notable that the Italians who emigrate to the United States largely return.

Effects of Emigration.—There are two views with regard to emigration: one unfavourable, viz., that it is a drain on population, reducing its economic strength and interfering with social and political relations; the other, looking on the emigration as a benefit from over-population and a congested labour market. As a matter of fact, emigration has not succeeded in diminishing the population of Europe, which, on the contrary, doubled during the 19th century. The one great exception is Ireland, where population declined from 8,175,124 in 1841 to 4,458,745 in 1901. From 1851 to 1901 the total emigration from Ireland was 3,881,246 or 72-5% of the average population. Emigration, carrying off the young men and women, also reduced the Irish marriage and birth-rates, which were almost the lowest in Europe. But hitherto the countries of strongest emigration (England, Germany, &c.) have shown practically undiminished birth and marriage-rates and a steady growth in population. The intensity of emigration is measured not by the absolute number of emigrants, but by the number of emigrants to the total population. Its effect is shown by comparing the number of emigrants with the excess of births over deaths per 1000 of the population. This is shown in the following table (1905):—
It will be observed that, with the exception of Ireland and Italy, wherever there is a heavy emigration there is usually a considerable excess of births over deaths, i.e., natural increase up for the loss by emigration. Even taking Great Britain and Ireland together, the loss by emigration per annum has not been very large, as is shown by the following table:

<table>
<thead>
<tr>
<th>Annual Emigration per 1000 of the Average Population of Great Britain and Ireland.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Year</td>
</tr>
<tr>
<td>1853-1855</td>
</tr>
<tr>
<td>1856-1860</td>
</tr>
<tr>
<td>1861-1870</td>
</tr>
<tr>
<td>1871-1875</td>
</tr>
</tbody>
</table>

Even in particular districts where emigration is heavy the loss is made up by births. For instance, in 1891 the emigration from the provinces of West Prussia and Pomerania was extraordinarily heavy—10% and upwards. In these provinces the excess of births over deaths was 19.6 per mille. Emigration may give temporary relief to congested districts, but it is not in itself a remedy for so-called overpopulation.

It is difficult to analyse closely the economic effect of emigration, because so much depends upon the character of the emigrants and the condition of the labour market. The following considerations have been urged at different countries, which computed the excess of births over deaths as 19.6 per mille. Emigration may give temporary relief to congested districts, but it is not in itself a remedy for so-called overpopulation. It is the man of energy, of some means, of ambition, who takes the chances of success in the new country, leaving the poor, the indolent, the weak and crippled at home. It is maintained that such emigration represents a process of selection which is unfavourable to the home country.

On the other side, it is said that the men who are doing well at home are the ones least likely to emigrate, because they have least to gain. Modern means of transportation have made the voyage so cheap that almost any one is able to go. It is therefore the restless, the unsuccessful, or at least those not fitted for the strenuous conditions of the new country, who emigrate. The supply of labour is somewhat reduced, but wages are kept up for those who remain. Those who go find means of bettering their own condition beyond the seas, where they become producers of food and raw material for the home country, and at the same time customers for her manufactured products. Emigration is therefore an economic gain, both directly and indirectly. It is evident from these arguments that no general answer can be given to the question. In some cases it may be an evil; in most, when conducted under normal conditions, it would seem to offer little danger.

The same remark would hold true in regard to the social and political effects of emigration. In some cases, by taking away the strong, self-reliant and energetic, it may result in the deterioration of the rest of the population. In other cases it allows restless spirits who have failed at home to try again elsewhere. Often in cases of political revolution the members of the defeated party have sought refuge abroad, as, after the French Revolution of 1848. In case of conquest the conquered nation takes to emigration on an extensive scale, as after the absorption of Alsace-Lorraine by Germany in 1871. The movement may be aided by the state or by private associations. Of such character have been the state-aided emigration from Ireland, and the assisted emigration of paupers, criminals and other persons in the effort to relieve a congested population, or simply from the desire to get rid of undesirable members of the community. Such efforts fail if the new countries are unwilling to admit these persons. Finally, we have the expulsion of the Jews from Russia as an example of the effort of a community to get rid of an element which has made itself obnoxious to the local sentiment.

Effects of Immigration.—The effects of emigration are negative in character; those of immigration are positive. (a) On population: immigration, of course, in the case of a population of new countries, and greatly accelerates the growth by natural increase, especially as the immigrants are in the most productive ages of man, which is not the case in Ireland. In the United States, for instance, out of a population of 76,390,000 in 1890, there were 4,350,000 who were either foreign-born or who had one or both parents foreign-born. This does not mean that the population would have been two million less had there not been any immigration; for the rate of natural increase among the native-born would have maintained itself. Nevertheless, immigration has probably stimulated the growth of the country. (b) Economic effects: The economic gain of immigration is evidenced in the earnings of the immigrants themselves, as well as their available labour force, that is, to the number of adults engaged in the work of producing wealth.

According to the United States census of 1900, out of 29,143,193 (1900) persons engaged in gainful occupations, 5,851,399 or 20.2% were of foreign birth. If we add to these the native whites of foreign extraction (5,300,924) we have 11,152,323 persons of foreign extraction or 39.4% of the total labour force. The foreign-born alone constituted 10.4% of the total number of persons engaged in agricultural pursuits; 11.4% of those in professional services; 25.7% in domestic and personal services; 17.2% in trade and transportation; and 35.6% of those engaged in manufacturing and mechanical industries. In addition to these, the native whites of foreign parentage constituted, in agriculture, &c., 10.6%, in professional services, &c., in domestic and personal service, in trade and transportation, 25.7% in manufacturing and mechanical, 25.4% of all those engaged in those occupations. The labour force of the country is thus made up very largely of immigrants and the children of immigrants.

Attempts have sometimes been made to put a money value on the economic gain by immigration. The amount of money brought from abroad for the support of families and friends at home is only a small fraction of the money sent back by immigrants for the support of families and friends at home or to aid them in following. The valuable element in the able-bodied immigrant himself represents a saving of production. As already said, in the United States, it is stated, for instance, that an adult slave used to be valued at about $800 to $1,000, so that every adult immigrant may be looked upon as worth that sum to the country. Or, it has been said that an adult immigrant represents what it would cost to bring him up from infancy to the age, say, of 15. This has been estimated by Ernst Engel as amounting to $550 for a German child. The most scientific procedure, however, would be to determine the probable earnings of the immigrant during the rest of his lifetime, and deduct his expenses of living. The remainder represents his net earnings which he will contribute to the well-being of the new country. W. Farr reckoned this to be, in the case of unskilled English emigrants, about £175. Multiplying the total number of adult immigrants by any one of these figures, we get the annual value of immigration. Such attempts to put a precise money value on immigration are futile. For, as the question of the ultimate economic gain of an immigrant is what has to cost to bring him up only if he is able-bodied, honest and willing to work. If he is disappointed, crippled, sick, he is a gain to the country instead of a gain. So, too, the immigrant is worth his future net earnings to the community only if there is a demand for his labour.

Social and Political Effects of Immigration.—The influx of millions of persons of different nationality, often of a foreign language and generally of the lower classes, would seem to be a danger to the home country of a community. The United States, for instance, has felt some inconvenience from the constant addition of foreigners to its electorate and its population. The foreign-born are more numerously represented among the criminal, dependent and classes than their numerical strength would justify. They also tend to segregate more or less, especially in large cities. Nevertheless, the process of assimilation goes on with great rapidity; it is a well proved fact that assimilation proceeds with a considerable extent. The influence of the physical environment leads to the adoption of the same mode of life. The most powerful influences, however, seem to be social. These are common school education, the language and manners of the community, and especially American political life, which is granted to all male adults after five years' residence; and the general influence of social standards embodied in laws, institutions and customs already established. Doubtless this is an effect of the natural and modifying effect on American life; but on the whole the power of a modern civilized community working through individual freedom of action and elements of organization from it too radically has been displayed to a remarkable degree.

Restriction of Immigration.—New countries have sought to escape certain evils of indiscriminate immigration. These evils were as follows: the children of immigrants, who were sickly, sometimes insane or mentally diseased, in mind or body, and persons unable to support themselves. By the Acts of 1882 and 1893 such persons were refused admission to the United States, and, when rejected, the steamship companies were required to take them back. The number debarred from 1896 to 1905 is shown in the following table:

No law of international comity is violated by the refusal to receive these unfortunate. They should be taken care of at home. The English legislature in 1905 passed an act to prevent the landing of undesirable aliens, and the number refused admission in 1906 was 493. (b) Immigration sometimes increases the competition in the labour market, and thus lowers wages. One case is particularly aggravating, viz. when employers import foreign labourers in order to take the place of their men who are on strike. In 1886 the United States passed what is called the Contract Labor Law, forbidding the landing of any person who is under contract to perform labour in the United States. It is very difficult to discover such cases, but the number rejected is fairly large (see table above). (c) The immigration of men of alien race who refuse to assimilate with the natives is said sometimes to be a danger to the country. This at least is the excuse for the entire exclusion of Chinese labourers from the United States since 1882 (provisions made more severe in 1888 and 1892) (see also the article Coolie).

**Internal Migration.** In modern times there is constant movement of population within national lines, from section to section, and especially from rural districts to the cities. No record is kept of this, and we can trace it only through the census statistics of birthplace. In the United States, for instance, it was shown in 1890 that more than 21.5 per cent. of the native-born inhabitants were born in a state other than that in which they were born. Still further, it appears that about one-half of the native-born inhabitants had moved out of the county in which they were born. In 1890 there were 2,133,699 natives of the state of New York living in other states. The movement is principally westward in direction and along parallels of latitude. For instance, New York has made large contributions to the population of Ohio, Michigan, Indiana, Wisconsin, Iowa and so on. Virginia has contributed largely to the population of West Virginia, Kentucky, Ohio, Indiana, Illinois and Missouri. In Europe there is a similar movement; but it is difficult to make comparisons, because of the differences in the administrative areas. In England in 1891, 71.6% of the population were residing in their native county; in Prussia, 69.7% in the kreis; in France, 81.7% in the department; in Austria, 80.2% in the lach; in Switzerland, 82.1% in the canton where they were born (Webber, *Growth of Cities*, p. 249). The most important phase of internal migration is the movement from the rural districts to the cities. The statistical results are shown in the following table extracted from the admirable work of Weber, just quoted—

**Percentage of Population living in Towns of 10,000 and over at Three Periods.**

In England and Wales the rural population increased in the aggregate during the first half of the 19th century, but at a gradually diminishing rate; in the second half of the century the population declined with varying regularity, until the decennial 1891-1900, when there was an increase. But notwithstanding this aggregate increase there are many rural districts which still show a declining population. The urban population is increasing, as shown in the following table:

Somewhat the same phenomenon is seen in France. According to the census of 1891 not less than 55 out of the 87 departments had decreased in population; and out of the 32 that had increased, 17 showed a decrease in their rural parts when the large towns were deducted. In Germany the towns of 10,000 and over show a much more rapid increase than the rural districts; and the same fact is generally true of the rural counties of Europe. This more rapid increase of population in cities is due only in part to migration from the country. Until the 19th century deaths generally exceeded births in cities, so that if it had not been for constant immigration the cities would not only not have grown, but would have decreased in population. Cities grow more rapidly now than formerly, because the excess of deaths over births has been turned into an excess of births over deaths. Thereby the cities are becoming less dependent upon immigration for increase of population than formerly, but the migration still goes on. The causes of migration from country to city are mainly economic. In early stages of culture men are scattered over the country, or at most gathered together in hamlets and villages. Each of these is self-sufficing, having its own farmers and handicraftsmen, and producing what it needs. With the beginning of exchange commercial centres spring up, situated on navigable streams and especially at points where land or water journeys are broken. With the growth of manufactures, industrial centres spring up where the division of labour can be fully provided for. In modern times two factors have accelerated this process, viz.: (1) the building of railways, which have developed commerce to a very great degree and favoured the large towns at the expense of the small; and (2) the invention of machinery, which has greatly increased the possibility of division of labour and manufactures on a large scale. The old handicraftsmen has been superseded by machine labour and the village artisan by the factory hand. At the same time improvements in agriculture and the opening up of new countries have enabled the modern community to gain its food and raw material with a less expenditure of labour force, and the surplus agricultural population has gone to the city. The attractive influence upon individuals has been higher wages, greater scope for the ambitious, and the social advantages of city life.

The general laws of internal migration may be summarized (according to Ravenstein) as follows:

1. The great body of migrants proceed only a short distance.
2. The process of absorption goes on as follows: The inhabitants of the country immediately surrounding a town of rapid growth flock into it; the gaps thus left in the rural population are filled up by migrants from more remote districts, until the attractive force of one of the rapidly-growing cities makes its influence felt, step by step, to the most remote corner of the land. Migrants enumerated in one centre of absorption will consequently grow less with the distance, proportionately to the native population which furnishes them.
3. The process of dispersion is the inverse of that of absorption, and exhibits similar features.
4. Each main current of migration produces a compensating current.  
5. Migrants proceeding long distances generally go by preference to one of the great cities of commerce or industry.  
6. Additional landmarks are less migratory than those of the rural parts of the country.  
7. Females are more migratory than males.  

AUTHORITIES.—The statistics of migration are to be found in the official returns of different countries, especially the statistical tables relating to emigration and immigration published by the British Board of Trade, and the Reports (annual) of the Commissioner-General of Immigration of the United States. For general discussion see Philippovich, Auswanderung und Auswanderungspolitik (Leipzig, 1892). An exhaustive bibliography will be found in an article by same author, “Auswanderung,” in Handwörterbuch der Staatswissenschaft (1902). The Mayo-Smith, Emigration and Immigration, with bibliography (New York, 1890). For a critical study of MIGRATION, A. F. Weber, Growth of Cities (New York, 1890). See also Ravenstein, “The Laws of Migration,” in Journal of Royal Statistical Society (1885 and 1886). Professor Flinders Petrie, in his Huxley Lecture for 1906 on Migrations (reprinted by the Anthropological Institute), deals with the mutations and movements of races from an anthropological standpoint with profound knowledge and originality.  

(R. M.-S.; T. A. I.)  

MIGRATION, in Zoology. In zoology, considerable importance attaches to the problems of migration, by which is meant the wandering of living creatures into another, usually distant, locality in order to breed there; this implies a return, and the double phenomenon is annual. All other changes of the abode are either sporadic or epidemic, or fundamentally permanent within lesser limits. Further, migration should not be confounded with “spreading,” which proceeds steadily, and in epicycles, with a totally different result. It need not be emphasized that hard and fast lines between these phenomena do not exist; they are often a question of degree. For instance, when the common toad, which is a strictly terrestrial creature, wanders every spring to a frequently distant pool in order to spawn there, this is a true migration. The same applies, strictly speaking, to those insects which hibernate in the ground, at the root of the tree on which they feed and breed. The grey plover breeds in the arctic circle and winters in equatorial countries. To complicate matters further, it is not necessary that the migration be undertaken periodically, more than once, by the same individual. For instance, the common eel ascends the rivers as an elver in its youth; years after it returns to the sea, there to breed and to die, whilst other fishes come and go, year after year. Further, some of the larger birds, for instance swans and cranes, are still immature in their second year, and yet they migrate like their older relations. It seems permissible to use this fact as an indication that the breeding as such is not the prime reason for migration. The fundamental impelling element must have been the want of food, and what we usually understand by migration cannot suddenly have sprung into existence to its full extent, but is more likely the cumulative effect of the doings of countless generations. The faculty of shifting the abode was of course always there, the necessity of moving further on was also present, and those which went in the wrong direction came to grief, while the others flourished and returned with their progeny. They did not at first cover enormous distances, but just enough to find unoccupied ground. The annual repetition became an established habit. The bird's way of existence was not instinct. There can be but little doubt that the prime impulse was want of food. The new growing grass on the prairie or on the veldt attracts every year those creatures which live upon pasture. The inter-tropical belt of the world is so crowded with creatures that there is the keenest competition, whilst in the temperate and cold regions is a long winter quiescence unift for the support of many creatures, whereas in the summer these same regions are covered with new vegetation, with its concomitant abundance of insects and other invertebrates. The tables are decked again, and these opportunities are not wasted.  

The process of migration, in its most striking cases, is now very complicated. Many a bird goes actually to the arctic regions for the shortest of summers, but spends most of the year within the tropics. On the other hand there are many species which do not go so far north, but stop to breed in the intermediate regions. We must not take the extremes when trying to unravel the development of the problem. The periodical migrations of mammals, with their more limited extent and greater leisure, are less perplexing.  

It has been argued with some show of reason that the real home of a bird is that country in which it was born, in other words where the species breeds, but this in itself is no case a valid conclusion. It applies to most creatures, but it can well bear exceptions if we leave sentiment aside. When it comes to a question of domicile, the ten weeks' sojourn of the swift, Cypselus, in England are more than weighted down by the nine months or more which these birds spend in southern countries, although we do not know whether they are resident there or roam about. The breeding time is the busiest period of a bird's life; then the numbers of each species are suddenly multiplied, and so is the stress of providing food, and the particular food which is best for the young may not be available in every country. The idea that the arctic circle is the original home of the numerous kinds of birds which breed in it, whence they are now periodically driven away by stress, has been coupled with the glacial epoch, that supposed solution of so many difficulties. We have only to assume that the old, permanent home of these migrants was in the arctic region, that the progressing glaciation drove them away, of course towards the equator, and that, when times improved again, the birds returned to their old home. This sounds very plausible, but it involves huge assumptions. The birds, not the individuals, but the species, are supposed to have inherited such a loving reminiscence of their old home, that after thousands of years—with most of the small birds meaning as many generations—they returned at the first opportunity. It implies that their long continued sojourn in foreign lands, where—under this assumption—thousands of generations must have been bred and have spent all their lives, was not sufficient to naturalize them, so to speak, in other words to supplant the instinctive love of the primary ancestral home. That the last glacial epoch has driven the limit of many kinds of animals and plants farther south is as certain as that many have recovered the lost ground after the reversion of the glaciation, but it must have been a very slow and steady process of spreading. It may, and probably does, account for the present annual visitations of arctic lands, as a phenomenon which has been evolved de novo, which would have come to pass even if no birds had existed in pre-glacial times.  

How do birds manage to find their way, thousands and thousands of miles across land and water? This question has been extolled as a mystery of mysteries. It has been stated that the old birds show the way to the young, a speculation which does not apply to those many cases in which old and young notoriously travel at different times. It has been assumed that they travel by sight, taking advantage of certain landmarks; another untenable idea, since—experience having to be excluded in a flock of birds which made the journey for the first time—it implies that the young must have inherited the reminiscence of those landmarks! Others have likened the bird to a kind of magnetic needle, and Professor Silsbee, von Middendorff found some migration routes to coincide with the direction of the magnetic pole. The whole question reduces itself to a sense of direction, a faculty which is possessed by nearly all animals; in some it is present to an astonishing extent; but the manifestations of this sense vary only in degree. The cat which escapes out of the bag finds its way back, directly or after many adventures. The bee, after having loaded itself with pollen, returns by the proverbial line to the hive which may be a mile away, but, move the smallest obstacle in the mean that an inch to the right or left, and the bee will knock its head against the hive and blunder about; move the hive a few yards and bee after bee returning will be puzzled to find its hive again. They, maybe with the help of landmarks, have accustomed themselves to steer a course. Such instances need not be multiplied. The principle is the same whether
MIGRATION

the journey be one of a few yards or of many miles. Given
the sense of direction, it is no more difficult to steer a course
due north than it is to lay on south-east by east, provided
always the impetus to be on the move. There is no mystery,
except that we, the most intellectual of mankind, and our
wholly nigh have lost this sense. It is simply an instance of the
faculty through long-continued disuse.

The following account is to a great extent based upon

In almost all countries there are so-called "migrants" which arrive in
spring, and depart in autumn; others which
arrive in autumn, stop for the winter and depart in spring; and
others again—and these are strictly the "birds of passage"
which show themselves from time to time on the passage
through the country—without staying long in it, and their transient visits take
place about spring and autumn. These three apparently different
categories of migrants are all acted upon by the same impulse in
some or other way.

The species which resort to Britain and to other temperate countries
in winter are simply those which have their breeding quarters
much nearer the poles, and in returning to them on the approach
of spring are not doing exactly as do those species which, having
their winter abode nearer the equator, come to us with the spring.

The birds-of-passage proper, like our winter visitants, have
the basis for this migration, and the others
swarm. But with emigrants from the north, although well fitted for the
shape of so great a population at that season are deficient in certain neces-
sary for that journey, and this is borne out that even if such necessaries are not absolutely wanting,

This seems satisfactorily to explain the southward movement of
all migrating birds in the northern hemisphere; but when we con-
sider the return movement which takes place some six months
later, doubt may be entertained whether scarcity of food can be
assigned as its sole or sufficient cause, and perhaps it would be safest
to anay to come to any decision on this point. On one side it may be
suggested in the migration of the wanderers that the threat of cold
is a more material consideration than that of food; and on the other side
that of loss of residence, from the season of cold in the south, is a

A. R. Wallace in some remarks on the subject (Nature, X. 459)
ingeniouly suggests the manner in which the habit of migration
has come to be adopted."

In a few is the habitat of 'survival of the fittest' will be found to have had a powerful
influence. Let us suppose that in any species of migratory bird,
breeding can as a rule be solely accomplished in a given area;
and further, that during a great part of the rest of the year
their sufficient food cannot be obtained in that area. It will follow
that those birds which do not leave the breeding area at the proper season will
be unable to breed, and the species will be consigned to extinction; which will also be the fate
of those which do not leave the feeding area at the proper time.
Now, if we suppose that the two areas were (for some remote ancestor of the existing species) coincident, but by geological and climatic
change one of them, or both, have been changed, and that the
people of these parts of the world have changed the habits of
migration, that not a single song-thrush can be found from the end of November
until the end of January, while in others examples can always be seen.

Much the same may be said of the redbreast. Undoubtedly resident
as a species, yet its song will reveal the fact that mothers
are subject to very considerable variation, according to the season of
the year. At no time do our redbreasts collect in bands, but
towards the end of summer they may be seen in the south of England
successively passing onward, the travellers being mostly—if not
wholly—young birds of the same; and so the great majority dis-
appear, departing it may be safely presumed for more southern
countries. If these birds are as late as June, and found in
France and then in Italy, are well supplied with this species.

But the migratory influence affects, though in a lesser degree, many
of our other birds that remain with us. Every bird of
the northern hemisphere is to a greater or less degree migratory
in some part or other of its range.

Wint of food, and perhaps of the special, proper kind during the
breeding season to be the most obvious cause of migration,
and none can wonder that those animals which possess the power
of removing themselves from a place of scarcity should avail
themselves of it, while it is unquestionable that birds possess this faculty in
large number. It is a fact. Even among the very social birds it is
monly speak of as sedentary it is only the adults which maintain
their ground throughout the year. It has long been known that
birds are not merely drive of young. In some, like the young
own haunts so soon as the young are able to shift for themselves.

The reason generally, and no doubt truly, given for this behaviour,
which at first sight appears so unnatural, is the impossibility of
both parents and progeny getting a livelihood in the same vicinity.

The practice, however, is not limited to the birds-of-prey alone,
but is much more universal. We find it to obtain with the red-

breast, and if we watch our feathered neighbours closely we shall
discover in a short time that most of them indulge in it. The period of expulsion,
it is true, is in some birds deferred from the end of summer or the
autumn, in which it is usually performed, until the following spring,
while others seem to leave from the moment the change of seasons has

In principle F. W. Hutton had already foreshadowed the same
should outstrip the weaker by a very perceptible distance, and it can hardly be doubted that in most species the males are as they are bigger than the females. Some observers assert that the same thing takes place in the return journey in autumn—seen when the first migrants appear, first of the young, then the males, having finished their molt of autumn, and the females—but on this point others are not so sure, which is not surprising when we consider that the majority of observations have been made on the coast. It is the business of the return journey the island Passeres, to which the remark is especially applicable—in the British islands, France, North Germany and the Russian empire—for the same reason. The increasing inequality in the speed of travelling will not have become so great will be another matter to be noticed. It seems to be that there is any difference in the size of birds of the same species, particularly in the individual birds, to perform the most extensive journeys would be naturally those with the longest and broadest wings, and in support of this view it certainly appears that in some of the smaller migrants—such as the whole family of the Alcedo oenanthe—the species which reach the extreme north of Europe and there pass the summer possess greater mechanical powers of flight than the use of the same species which stop short on the shores of Mediterranean. It may perhaps be also inferred, though precise evidence is wanting, that these same individuals push further to the southward in winter than those which are less favourably situated, and almost always the same species, and it may well be so with individuals. H. B. Tristram has remarked (Ibis, 1865, p. 77) that, in many genera of birds, "the young of the species naturally have also the most extended southerly range; and that these species, when they have reached the highest latitudes for nidification also pass further than others to the southward in winter," fortifying his opinion by examples and statistics. But these are two exceptions.

For many years past a large number of persons in different countries have occupied and amused themselves by carefully registering the dates on which various migratory birds first make their appearance, and there is now an abundance of records so compiled. Still it does not seem that they have been able to determine what connexion, if any, exists between the arrival of birds in the west and their departure in the east. The causes which have been made about the weather in the places whence the travelers are supposed to have come. As a rule it would seem as though birds were not dependent on the weather to any great degree. Occasionally the swallows or the nightingales may have been delayed, but most sea-fowls may be trusted, it is said, as the almanac itself. Foul weather or fair, heat or cold, the puffins (Fratercula arctica) repair to some of their stations punctually on a given day as if their movements were regulated by clockwork. Whether they have come from far or from near we know not, but other birds certainly come from a great distance, and yet none which we know are known to have been seen in the regularity with which certain species disappear vast inferior; the whole time of its summer home—in most parts of England on the first days of August—and how rarely it is seen after that time is past. It must be allowed, however, that, with few exceptions, the mass of evidence has never been worked out and digested so as to lend itself to any general rule. Before it would be premature to say that little would come of it, which is the result of those exceptions is not very encouraging. E. von Mireiffel has fully and convincingly shown in his treatise on Birds throughout the Russian Empire, but the insight into the question afforded by his published labours is not very great. His chief object has been to trace what he has termed the species (feos = speciess, intrinss = adveners) or the lines of simultaneous arrival, and in the case of seven species these are laid down upon the maps which accompany his treatise. The lines are found by taking the average date of arrival and nothing is seen of the rate of successful flight. In this instance it appears that the grey or hooded crow, Corvus cornix, which notoriously is not a bird, flies from Hedigoland to the coast of Lincolnshire in England, and yet the rate of crossing the ocean is so gradual that it seems perfectly certain that the bird has not been carried across by the wind or any other agency. To the little bluetbrow he assigned a velocity of two hundred and forty miles an hour, a statement as silly as that made by some fanciful observer in Portugal who convinced himself that birds could fly at a rate of 300 miles an hour, without a doubt these birds that a few hours later were skimming over the Portuguese pine forests on their way to Central Africa. Fifty miles an hour would be a high average for a bird like this, and tell how long such birds can continue their flight without interruption. Yet we seem to know that is not a few kinds manage, in various parts of the world, to cross enormous distances without the chance of a break. It was Gaetke's notion that migration was for the most part carried on at such a height in the air as to be beyond our ken, and that what
MIGRATION

comes to our perception consists chiefly of the abortive or unsuccessful attempts, when birds are checked in their course, and being unable to proceed, attempt at night to fly in a more suitable direction. Of various reasons birds could not fly at very great heights in very thin air, as experiments with pigeons released from balloons have shown, and the condor, by flying far above the clouds the migration proceeds beyond our ken, and if for some reason or other they are below the clouds the phenomenon becomes to us very noticeable. It is well known that birds of passage, flying at night, are rarely seen soaring overhead, while on nights that are overcast, misty and dark, especially if slight rain be falling, flocks may often be heard almost continuously.1 It is in such weather, continues Newton, that birds while migrating are most vociferous, doubtless with the result that thereby the company of fellow-travellers is kept together.

There yet remain a few words to be said on what may be termed Exceptional Migration, that is when from some cause or other the ordinary practice is broken through. The erratic movements of the various species of crossbill (Loxia) and some allied forms afford probably the best example; and a number no other than the same, what part of the country or at what season of the year he may not fall in with a company of the common crossbill (L. curvirostris), and the like may be said of many other species. The birds are known to breed in the south, and overran in the north, and in any locality in the breeding season, as in the autumn of 1844, or the spring, the ascending small birds, whose young can be reared in greater safety. Still others, known as anadromous fishes, feed and mature in the sea, but ascend the rivers where they were born to spawn, and of the sea and fresh-water species the salmon, sturgeon and striped bass in American waters; Clupea alosa, the Allis shad, and C. finna, the Twait shad, Alepocephalus rostratus, the "mojarfish" of the Pacific coast, are well known examples. The most remarkable case of the anadromous instinct is found in the king-salmon or quinnat (Oncorhynchus tshawytscha), of the Pacific coast. This great fish spawns in November, at and approaches two pounds, and an average weight of twenty

There is no sense in this. The overcrowded condition of their home impels them to leave, and this impulse continues blindly, and is not attended to until they are at or near the sea. A year or two after the irruption not a lemming is there to be found, and where during their stampede they come across suitable districts, they find these already occupied by resident lemmings. But there is no doubt taken place often during the world's history; and yet such sporadic stampedes into a foreign country have never much resembled those of birds, but very little is known about these fishes. Take the incredible masses of herrings and their kindred; the collecting of the cod, haddock, and allied species in the North Sea, Newfound-land, etc. D. S. Jordan (A Guide to the Study of Fishes, New York, 1905) some kinds are known mainly in the waters they make their breeding-homes, as in Cuba, southern California, Hawaii or Japan, in individuals or groups of thousands, and not in masses as the tunny, which has a world-wide distribution, arrives off the south coast of Portugal in the month of May; enormous numbers pass through the Straits of Gibraltar and support great fishing industries in the Mediterranean. In the month of August they return to the ocean (A pesaco do Atum no Algarve em 1896, por D. Carlos de Braganza, Lisboa, 1899; with many maps).

Many of the sea-water fishes (Cetacea) have flown the large streams in the spring, ascending the small brooks, where their young can be reared in greater safety. Still others, known as anadromous fishes, feed and mature in the sea, but ascend the rivers where they were born to spawn, and of the sea and fresh-water species the salmon, sturgeon and striped bass in American waters; Clupea alosa, the Allis shad, and C. finna, the Twait shad, Alepocephalus rostratus, the "mojarfish" of the Pacific coast, are well known examples. MIGUEL—MILAN

437

MIGUEL, MARIA EVARIST (1862-1866), usually known as Don Miguel, whose name is chiefly associated with his pretensions to the throne of Portugal, was the third son of King John VI. of Portugal, and of Carlota Joaquina, one of the Spanish Bourbon family. He was born at Lisbon, 10th August, 1822. In 1850 he accompanied his parents in their flight to Brazil, where he grew up an uneducated and fanatical debauchee; in 1857, on his return to Europe, it is said that he had not yet learned to read. In 1862 his father swore fidelity to the new Portuguese constitution which had been proclaimed in his absence; and this led Carlota Joaquina, who was an absolutist of the extremest Bourbon type, and hated her husband, to seek his dethronement in favour of Miguel her favourite son. The insurrections which ensued (see PORTUGAL) resulted in the exile of the King, who left Lisbon on 27th October, 1822. In 1823 he retired to the Bay of Corunna, with the support of a small party of which his mother was the ruling spirit, he got himself proclaimed sole legitimate king of Portugal in July. His private life was characterized by the wildest excesses, and he used his power to oppose all forms of liberalism.

The public opinion of Europe became more and more actively hostile to his reign, and after the occupation of Oporto by Dom Pedro in 1832, the destruction of Miguel's fleet by Captain (afterwards Sir Charles) Napier off Cape St Vincent in 1833, and the victory of Saldana at Santarem in 1834, Queen Christina of Spain recognized the legitimate sovereignty of Maria, and in this was followed by France and England. Dom Miguel capitulated at Evora on the 20th of May 1834, renouncing all pretensions to the Portuguese throne. He lived for some time at Rome, where he enjoyed papal recognition, but after- wards retired to Bronnach, in Baden, where he died on the 14th of November 1866.

MIHRAB, a term in Mahomedan architecture given to the niche which in a mosque indicates the direction of Mecca, towards which the Moslems turn when praying.

MIKADO, (Japanese for "exalted ruler"), the poetical title associated by foreign countries with the sovereign of Japan; the Japanese title, corresponding to the English "emperor," is tenno, the term kōkai being used of his function in relation to external affairs. By the constitution of 1889, the emperor of Japan transferred a large part of his former powers as absolute monarch to the representatives of the people, but as head of the empire he appoints the ministers, declares war, makes peace and concludes treaties, acting generally as a constitutional sovereign but with all the personal authority attaching to his august position. The history of the mikados goes back to very early times, but from 1600 to 1868 the real power was in the hands of the shoguns, who nevertheless were in ceremonial theory the subjects of the mikado. The revolution of 1868 restored the real power into the hands of the mikado. (See JAPAN: History; and MIKADO-HIRO.)

MIKIRS, a hill tribe of India, occupying two or three detached tracts in Nowgong and Shibasagar districts of Eastern Bengal and Assam, known as the Mikir hills. In 1901 their total number was returned as 87,956. Mikir is the name given to them by the Assamese; they call themselves Arleong, which means "man" in general. They have long settled down to agriculture, and are distinguished from the tribes around them by the absence of savagery. Their language, which has been studied by missionaries, seems to connect them with the Kuki-Chin stock on the Burmese frontier.

MIKLOSICH, FRANK VAN (1831-1891), Austrian philologist, was born at Luttenberg, Styria, on the 29th of November 1813. He graduated at the university at Graz as a doctor of philosophy, and was for a time professor of philosophy there. In 1838 he went to Vienna, where he took the degree of doctor of law. He devoted himself, however, to the study of Slavonic languages, abandoned the law, and obtained a post in the imperial library, where he remained from 1844 to 1862. In the former year he published a noteworthy review of Bopp's Comparative Grammar, and this began a long series of works of immense erudition which completely revolutionized the study of Slavonic languages. In 1849 Miklosich was appointed to the newly created chair of Slavonic philology at the university of Vienna, and he occupied it until 1866. He became a member of the Academy of Vienna, always worked in its secretarial and historical and philosophical section, a member of the council of public instruction and of the upper house, and correspondent of the French Academy of Inscription. His numerous writings deal not only with the Slav languages, but with Rumanian, Albanian, Greek, and the language of the gypsies. Miklosich died on the 7th of March 1891.

MILÁN (Ital. Milano, Ger. Mailand, anc. Mediolanum, q.v.), a city of Lombardy, Italy, capital of the province of Milan, 93 m. by rail E.N.E. of Turin. Pop. (1881), 321,839; (1900), 566,613. It is the seat of the army corps, the chief financial centre of Italy and the wealthiest manufacturing and commercial town in the country. It stands on the little river Olona, near the middle of the Lombard plain, 400 ft. above sea-level.

The plain around Milan is extremely fertile, owing at once to the richness of the alluvial soil deposited by the Po, Ticino, Olona and Adda, and to the excellent system of irrigation. Seen from the top of the cathedral, the plain presents the appearance of a vast garden divided into square plots by rows of mulberry or poplar trees. To the east this plain stretches in an unbroken level, as far as the eye can follow it, towards Venice and the Adriatic; on the southern side the line of the Apennines from Bologna to Genoa closes the view; to the west rise the Maritime, Cottian and Graian Alps, with Monte Viso as their central peak; while northward are the Pennine, Helvetic and Rhaetian Alps, of which Monte Rosa, the Saasfrat and Monte Leone are the most conspicuous features. In the plain itself lie many small villages; and here and there a larger town like Monza or Saronno, or a great building like the Certosa of Pavia, makes a white point upon the green way. The climate is changeable and trying; the intensely hot, in winter very cold. Snow is often seen, and the thermometer is frequently below freezing-point.

In shape Milan is a fairly regular polygon, and its focus is the splendid Piazza del Duomo, from which a number of broad modern streets radiate in all directions. These streets are connected by an inner circle of boulevards, constructed just outside the canal, which marks the site of the town moat. The
The arches of Porta Nuova are almost the last trace of the inner circuit, constructed after the destruction of the city by Frederick Barbarossa, to which also belonged the Porta del Fabbric, demolished in 1464. Curious reliefs from the Porta Romana are to be seen in the museum. Within this circle the majority of the streets are narrow and crooked, while those between it and the bastions, though broader on the whole, have but little regularity. An outer circle of boulevards, planted with trees and containing the view of the suburbs, lies just beyond the present walls of the city, erected by the Spaniards in the 16th century; the entire length of these boulevards is traversed by an electric tramway 7 ft. long.

Occupying the end of the Piazza del Duomo is the famous cathedral. It is built of brick cast in marble from the quarries which Gian Gaetano Visconti gave in perpetuity to the cathedral chapter. It was begun in 1386. The name of the original architect is unknown, but it is certain that many German masters were called to Milan to assist the Italian. It was then the largest church in existence, and now, after St Peter's at Rome and the cathedral of Seville, the Duomo of Milan is the largest cathedral in Europe; it covers an area of 14,000 sq. yds., and can hold 40,000 people. The interior is 486 ft. long, 240 ft. wide; the nave is 157 ft. high, and the distance from the pavement to the top of the tower is 356 ft. The style is Gothic, very elaborately decorated, but it shows many peculiarities, for the work was continued through several centuries and after many designs by many masters, notably by Amadeo, who carried out the octagonal cupola (the pinnacle of which dates from 1774), and by Tibaldi, who laid down the pavement and designed a baroque facade. This last feature was begun and unfinished till 1805, when Napoleon caused the work to be resumed. With its Renaissance windows and portals this façade, though good in itself, was utterly out of keeping with the general style of the church, and in 1900 the removal of the inharmonious features was begun, to be replaced in a style strictly in accordance with the Gothic style of the rest of the building from the designs of Giuseppe Bertano. In shape the church is cruciform, with double aisles to the nave and aisles to the transepts. The roof is supported by fifty-two pillars with canopied niches for statues instead of capitals; the great windows of the choir, reputed to be the largest in the world, are filled with stained glass of 1844. To the right of the entrance is the tomb of Archbishop Heribert, the champion of Milanese liberty, while beside him rests Archbishop Otto Visconti, the founder of that family as a reigning house. The large bronze candelabrum in the left transept is said to be 13th century work. In a crypt under the choir lies the body of the cardinal saint Carlo Borromeo, who consecrated the cathedral in 1577. It is constructed of rock-crystal shrine, encased in silver, and is vested in full pontifical robes blazing with jewels. The roof of the cathedral is built of blocks of marble, and the various levels are reached by staircases carried up the buttresses; it is ornamented with a profusion of turrets, pinnacles and statues, of which last there are said to be no fewer than 4440, of very various styles and periods. In front of the cathedral rises a colossal bronze equestrian statue of Victor Emmanuel II.

There are two noteworthy palaces in the Piazza del Duomo. The first is the Palazzo Real, dating from 1774, but occupying the site of the earliest mansion of the Viscontis and the Sforzes; its great hall is a handsome chamber with a gallery supported by caryatides. Built into the palace is the ancient church of San Gottardo, a Romanesque building which was built by Azzzone Visconti in 1238-1339, and was the scene of the murder of Giovanni Maria Visconti in 1412. Its campanile is a beautiful example of early Lombard terra-cotta work. The second palace is that of the archbishops, the fine façade of which is the work of Fabio Magione. It has an older north colonnade, by some attributed to Romanesque, and many other later buildings without sufficient evidence, and a fine court with double colonnades by Tibaldi, to whom the back façade is due. The Palazzo della Ragione, erected in the Piazza dei Mercanti, just west of the Piazza del Duomo, the central point of the medieval city, in 1223-1238 by the podestà, Oldrado da Treseno, whose equestrian portrait in high relief adorns it, still exists in fine preservation. It is a brick edifice with a portico, erected by the Viscontis. A large hall on the upper floor to the south is the beautiful Loggia degli Osii erected in 1316, with two loggie or open porticoes one above the other, in black and white marble.

Among the most interesting buildings in Milan is the ancient church of S. Ambrogio, here St Ambrose baptized St Augustine; here he closed the doors against the emperor Theodosius after his cruel massacre at Tarragona; here first the Roman emperors caused themselves to be crowned with the iron crown of Lombardy, and the altar at which they took their coronation oaths is preserved. The church was built by Ambrose early in the 4th-century (on the site of a temple of Bacchus it is said), but as it stands it is a Romanesque basilica of the 12th century, recently well restored (like many other works of Milan and Lombardy, curious galleries over the façade, and perhaps the most perfectly preserved atrium in existence. The wooden door belongs to the original 6th-century church, it carvings with scenes from the life of David. In a great silver reliquary (modern) in the crypt lie the bones of St Ambrose, above which rises the high altars, which retains its original decorations, the only intact example. The altar is of gold and silver enriched with enamel and gems, and are the work of one Uovo, a German. The baldacchino, with sculptures of the 12th or early 13th century, is borne by four ancient columns of porphyry; the ceiling was covered with mosaics of the 9th-century, which, Burckhardt remarks, completely break with Byzantine tradition. In the side chapel of St Satiro are even earlier mosaics (5th century); there is also fine fresco by Borgognone (1470–1528). The lofty brick campanile (780–822) is among the earliest in Italy, and is decorated with coloured majolica disks. The court of the neighbouring canonica is by Bramante, the chapel and crypt of the monastery of S. Ambrogio, now the military hospital. S. Lorenzo, in the south portion of the town, dates from before A.D. 588, thus being practically contemporary with S. Vitale at Ravenna (though Burckhardt considers it to belong to about and to be a part of the thermes or palace of Maximian), but was burnt down and restored in 1071 (in the restoration Corinthian capitals were used as bases). Thirty-five of the arches of the nave were restored and a new facade added. It was restored, but collapsed again in 1573, and a great part of it had to be reconstructed, including the dome (1574–1591). The chapel of S. Aquilino, possibly a part of the original structure, contains the tombs of the 5th or 6th century. In plan the church is an octagon, supported at the corners by four square towers in brickwork, which belong to the original structure. The interior with its high vaults is a very fine one, and its successive architects has been very considerable. S. Eustorgio, one of the largest Gothic churches in Milan, with some Romanesque survivals, dates, as it stands, with its campaniile, from the 13th century, and has a nave and aisles of the old style. It has some interesting medieval works of sculpture, and a fine chapel (Cappella Portinari), with a good dome and a beautiful frieze of angels, built by Michelozzo in 1468, with a frieze of marble (sarcophagi with reliefs, supported by statues) of Peter Martyr (d. 1503), the Masterpiece of Giovanni di Balduccio of Pisa (1359); the walls of the church are decorated with important frescoes by Vincenzo Foppa of Brescia, S. Simpliciano, too, though originally Romanesque, is now in the main Gothic, and has been much altered.

S. Vincenzo in Prato (832), now restored to its basilican form, with nave and two aisles divided by columns and three apses, and with small, flat arcading on the exterior, which is in brickwork; S. Satiro, founded in 879; S. Babila, also restored to its original form, etc., are interesting for their Romanesque small dome and structure on the left of S. Satiro is earlier than the church, while the campanile is part of the original structure, though preserved in date by that of S. Ambrogo, which is one of the finest genuine campaniles. The main portion of the church of S. Satiro was Bramante's earliest work in Milan (after 1476). The church is painted in perspective (there was no room to build one), the earliest example of this style, in which so fine an architectural conception as the octagonal sacristy (before 1488), with niches below and a gallery above, with stucco decorations by Bramante himself (the frieze with putti and medallion is attributed to his successor, and is quite his best. The Cistercian abbey-church of Chiaravalle, 35 miles south of Milan, is a fine brick building in the plan of a Latin cross, with nave and two aisles with round pillars, with a lofty domed tower, the tower is octagonal, and there is a splendidly slender round pillars and cross vaulting, while the exterior is still quite Romanesque. It was founded in 1135 by St Bernard and consecrated in 1221. It is interesting as the model for many other churches in Lombardy, e.g. S. Maria del Carmine and
The cellars of the beginning of the 15th century, the most notable is the Palazzo Borromeo, which still preserves its Gothic courtyard. It has a good collection of Lombard pictures. At no great distance from S. Ambrogio, in the Corso Magenta, is the church of the Vincentians, which contains fragments of the 9th century basilica of Santa Maria in Arona, one of the first vaul ted Lombard architecture; the bas-reliefs of the ancient Porta S. Maria of Mil an, which is the entrance of the collection of San Giovanni in Conca; the tomb of Regina della Scala, the wife of Bernabò; the funeral monument of the Rusca family; the great portal of the palace of Pignolo Portinari, seat of the Banco Mediceo at Milan, a work of Michelangelo; a series of Renaissance sculptures, including works by Amado Mantegazza, Agostino Busti (sur named Bambaia), including fragments of the tomb of Gaston de Castiglione Worksheets show traces of the decorations executed under Galasso Scamozzi and Lodovico Il Moro, and one of them has a splendid ceiling with trees in full foliage, painted so as to cover the whole vaulting, ascribed to Leonardo da Vinci. In the upper room is placed a large collection of Milanese and central Italian ceramics, stuffs, furniture, bronzes, ivory, enamels, glass and historical relics; together with a picture gallery containing works by Vincenzo Foppa, Giampietrino, Bottraffio, Crivelli, Porzzone, Morone, Car ciani, Correggio, Ant onello da Messina, Tieplo, Guardi, Poter, Van Dyck and Riebe.

The finest of the modern thoroughfares of Milan is the Via Dante, constructed in 1888; it runs from the Piazza de' Mercanti to the spacious Foro Bonaparte, and thence to the Parco Nuovo, the great public garden in which stands the Castello Sforzesco. This park was once a national drilling ground, which was taken over by the municipality with a view to erecting upon it a new residential quarter, rendered necessary by the rapid growth of the city during the last twenty-five years of the 19th century. This design was happily abandoned, and around the Parco Nuovo has grown up a new quarter of wide streets, spacious gardens and private villas.

To the north of the castle is the Arena, a kind of circus erected by Napoleon in 1802; while facing the castle on the opposite side of the park is the Arco della Pace, begun by Napoleon in 1806 from the designs of Cagnola to mark the beginning of the Simplon Road, the Art finished by the Austrians in 1833. Leading from the Piazza del Duomo, the centre of Milan ese traffic, especially of electric trams, is the Corso Vittorio Emanuele. Connecting the piazza with the neighbouring Piazza della Scala is the famous Galleria Vittorio Emanuele, a great arcade in the form of a Latin cross, with an octagon in the centre, crowned at the height of 160 ft. with a glass cupola; it is roofed with glass throughout, and is 320 yds. long, 15 yds. wide and 94 ft. high. It has splendid façades at each end, and was constructed in 1865–1867 at the cost of £200,000; it is the finest of its kind in Europe.

The Via Morone near the Piazza della Scala is a collection of art treasures bequeathed to the town in 1879 by a Milanese patron, the Cavaliere Poldi-Pezzoli. It comprises valuable pictures, textile fabrics, arms, armour and a number of antiquities, and is exhibited in the house once occupied by the founder.

In the middle of the neighbouring Piazza della Scala stands Magni's monument of Leonardo da Vinci (1872). Opposite is the celebrated Teatro della Scala, built in 1778 on the site of a church founded by Beatrice della Scala, wife of Bernabò Visconti. After the San Carlo at Naples, it is the largest in Europe at 3600 spectators. Looking on to the piazza is the fine Palazzo Marino, the seat of the municipality since 1861; it was built by Galeazzo Alessi in 1538, to whom the site façade and the court are due, but was not completed until 1806, when the main façade was erected by Luca Beltrami. S. Fedele by Tibaldi (1569) is close by. Milan has a royal scientific and literary academy with a faculty of philosophy, a royal technical institute, a school of veterinary science, a royal school of agriculture, a polytechnic with the Bocconi commercial school (founded 1898) and numerous other learned and educational institutions. Milan has long been famous as one of the great musical centres and numerous students resort here for their musical education. There are many philanthropic institutions, the most interesting of which is the Albergo Popolare, an establishment conducted on lines similar to the houses established in England.

1 See F. Malaguzzi Valeri, G. A. Amadeo, scultore e architetto (Bergamo, 1898).
by Lord Rowton in 1894. Sport and athletics are provided by a number of clubs, notably the Touring Club Italiano, founded in 1894.

The modern industrial development of Milan, with its suburbs and neighboring towns, such as Monza, Gallarate, Soronno, Busto Arizzio and Legnano, has been noteworthy. Machine-making on a large scale is carried on by firms of celebrated F. Ballarin, B рестор, and Legnano. Minor industries are represented by workshops for the making of stoves, geodetic instruments; of telephone and telegraph accessories; dynamos, sewing-machines, bicycles and automobiles. There is also a large carriage industry. In textile industries silk is the most important; and in leather, Milan is greater than that dealt with at Lyons. Spanning and twisting are as highly developed as the weaving industry. Milan is also the centre of the Italian cattexdy and Coarse Industries.

The municipal schools of Milan are as well organized as in any other town in Italy, and the exhibit in connexion with them at the great international exhibition of 1906 was of interest. There were, in 1906, 76,000 pupils, and 47,068 teachers, and in the evening and holiday classes there were 10,724 older pupils; 2,109,902 free rations and 215,133 paid rations were distributed to 16,526 pupils, and douches were administered. Pizzoni found the mental qualities of the pupils of is interest. The international exhibition of 1906 held in Milan was of considerable importance, all the leading states of the world taking part in it. The retrospective exhibition of means of transport was interesting in view of the recent opening of the Simplon tunnel, the occasion of the exhibition. Among the most noteworthy exhibits were those of machinery, of automobiles and bicycles, of agriculture, of trade, of art, and architecture. Italian handicrafts, industries, of the city of Milan; besides which, all the countries exhibiting had their own separate pavilions.

The circle of the Duomo did not extend beyond the walls; but in that year it was found necessary, owing to the growth of the city and of municipal expenditure, to include the external quarters or Corpi Santi (a name also applied to the extramural portions of Como, Varese, Pavia), with their large industrial population. Since that time municipal finance has been in a prosperous condition.

The water supply, from wells some 180 ft. deep in the sub-soil, is fairly good; one of the towers of the Castello Sforzesco is used as a distributing centre, while the sewerage system consists of 48 m. of sewers on the single channel principle, with collectors discharging into the Vettaba, a tributary of the Lambrone.

History—(For earlier history see Mediolana.—After the establishment of the Lombard capital at Pavia in 569 Milan remained the centre of Italian opposition to the foreign conquest. The Lombards were Arians, and the archbishops of Milan from the 8th century had been the champions of orthodox beliefs. In the struggle was unequal, their attitude of resolute opposition to the Lombards gained for them great weight among the people, who felt that their archbishop was a power around whom they might gather for the defence of their liberty and religion. All the innate hatred of the foreigner went to strengthen the hands of the archbishops, who slowly acquired, in addition to their spiritual authority, powers military, executive and judicial. These powers they came to administer through their delegates, called vicarcounts. When the Lombard kingdom fell before the Franks under Charles in 774, the archbishops of Milan were still further strengthened by the close alliance between Charles and the Church, which gave a sort of confirmation to their temporal authority, and also by Charles’s policy of breaking up the great Lombard fiefs and dukedoms, for which he substituted the smaller counties. Under the confused government of Charles’s immediate successors the archbishop was the only real power in Milan. But there were two classes of difficulties in the situation, ecclesiastical and political; and their presence had a marked effect on the development of the people and the growth of the commune, which was the next stage in the history of Milan. On 12 September, 764, the archbishop was obliged to contend against the heretics or against fanatical reformers who found a following among the people; and on the other, since the archbishop was the real power in the city, the emperor, the nobles and the people each desired that he should be of their party; and to whichever party he did belong he was certain to find himself violently opposed by the other two. From these causes it sometimes happened that there were two archbishops, and therefore no central control, or no archbishop at all, or else an archbishop in exile. The chief result of these difficulties was that a spirit of independence and capacity of judging and acting for themselves developed in the people of Milan. The terror of the Hunnish invasion, in 890, further assisted the people in their progress towards freedom, for it compelled them to take arms and to fortify their city, rendering Milan more than ever independent of the feudal lords who lived in their castles in the country. The tyranny of these nobles drove the peasantry and smaller vassals to seek the protection for life and property, the equality of taxation and of justice, which could be found only inside the walled city and under the rule of the archbishop. Thus Milan grew populous, and learned to govern itself. Its inhabitants became for the first time Milanese, attached to the standard of St Ambrose—no longer subjects of a foreign conqueror, but a distinct people, with a municipal life and prospects of their own. For the further growth of the commune, the action of the great archbishop, Heribert (1018-1045), the establishment of the carroccio, the development of Milanese supremacy in Lombardy, the destruction of Lodi, Como, Pavia and the neighbouring cities, the exhibition of free spirit and power in the Lombard league, and the battle of Legnano, see the articles ITALY and Lombards. In 1175 an almost circular moat, still preserved in the inner canal or capybara, was constructed round the town; but in 1562 Frederick Barbarossa took and almost entirely destroyed the city, only a few churches surviving. The city with its walls was, however, rebuilt five years later by the allied cities of Bergamo, Brescia, Mantua and Verona.

After the battle of Legnano, in 1174, although the Lombard cities failed to reap the fruit of their united action, and fell to mutual jealousy once more, Milan internally began to grow in material prosperity. After the peace of Constance (1838) the city walls were extended; the arts flourished, each in its own quarter, under a syndic who watched the interests of the trade. The manufacture of armour was the most important industry. During the struggles with Barbarossa, when freedom seemed on the point of being destroyed, many Milanese vowed themselves, their goods and their families to the Virgin should their city come safely out of her troubles. Hence arose the powerful fraternities of the "Umiliati," who established their headquarters at the Brena, and began to develop the wool trade, and subsequently gave the first impetus to the production of silk. From this period also date the irrigation works which render the Lombard plain a fertile garden. The government of the city was in the hands of a pancrata or consiglio grande, including all who possessed bread and wine, or their like; the head of which must be unmanageable owing to its size, and reduced first to 2000, then to 1500 and finally to 800 members; (b) a credenza or committee of 12 members, elected in the grand council, for the despatch of urgent or secret business; (c) the consuls, the executive, elected for one year, and compelled to report to the great council at the term of their office.

The bitter and well-balanced rivalry between the nobles and the people, and the endless danger to which it exposed the city
owing to the fact that the nobles were always ready to claim the protection of their feudal chief, the emperor, brought to the front two noble families as protagonists of the contending factions—the Torriani of Valassina, and the Visconti, who derived their name from the offices of delegates which they had held under the archbishops. 

After the death of Visconti the 1327, when Frederick II. defeated the Guelph army of the Milanesi and captured their carriocommerce, Pagano della Torre raised and saved the remnants of the Milanese. This act recommended him to popular favour, and he was called to the government of the city—but only for the distinct purpose of establishing the "casta," a property tax which should fall with equal incidence on every citizen. This was a democratic measure which marked the party to which the Torriani belonged and rendered them hateful to the nobility. Pagano died in 1241. His nephew Martino followed as podestà in 1256 and in 1259 as signore of Milan, who the first time such a title was heard in Italy. The nobles, who had gathered round the Visconti, and who threatened to bring Ezzelino da Romano, the Ghibelline tyrant of Padua, into the city, were defeated by Martino, and 900 of their number were captured. Martino was followed by two other Torriani, Filippo his brother (1263-1265) and Napoleone his cousin (1265-1277), as lords of Milan. Napoleone obtained the title of imperial vicar from Rudolph of Hapsburg. But the nobles under the Visconti had been steadily gathering strength, and Napoleone was defeated and killed at Certosa in 1272; he ended his life in a wooden cage at Castel Baradello above Como.

Otto Visconti, archbishop of Milan (1262), the victor of Desio, became lord of Milan, and the house of Visconti, who ruled the city—except from 1352 to 1310—till 1447, giving twelve lords to Milan. Otto (1277-1295), Matteo (1310-1322), Galeazzo (1322-1328), Azzo (1328-1339), Lucchino (1339-1349) and Giovanni (1349-1354) followed in succession. Giovanni left the lordship to three nephews—Matteo, Galeazzo and Bernabò. Matteo was killed (1355) by his brothers, who divided the Milanese, Bernabò reigning in Milan (1354-1395) and Galeazzo in Novara (1355-1378). Galeazzo left three sons; Gian Galeazzo, who became sole lord of Milan by seizing and imprisoning his uncle Bernabò. It was under him that the cathedral of Milan and the Certosa of Pavia were begun. He was the first duke of Milan, having obtained that title from the emperor Wenceslaus. His sons Giovanni Maria, who reigned at Milan (1402-1412), and Filippo Maria, who reigned at Pavia (1402-1447), succeeded him. In 1412, on his brother's death, Filippo united the whole duchy under his sole rule, and attempted to carry out his father's policy of aggrandizement, but without success.

Filippo was the last duke of the Visconti house. At his death a republic was proclaimed, which lasted only three years. In 1450 the general Francesco Sforza, who had married Filippo's only child Bianca Visconti, was made duke of Milan by right of conquest if by any right. Under this duke the castello was rebuilt and the canal of the Martesana, which connects Milan with the Adda, and the Great Hospital were carried out. Francesco was followed by five of the Sforza family. His son Galeazzo Maria (1466-1476) left a son, Gian Galeazzo, a minor, whose guardian and uncle Lodovico (il Moro) usurped the duchy (1479-1500). Lodovico was captured in 1500 by Louis XII. of France, and was replaced for the next five years by Gian Galeazzo, who became duke of Milan by seizing and imprisoning his uncle. In the partial settlement which followed the battle of Rignano, Massimiliano Sforza, a protégé of the emperor, was restored to the throne of Milan, and held it by the help of the Swiss till 1525, when Francis I. of France reconquered the Milanese by the battle of Marignano, and Massimiliano resigned the sovereignty for a revenue from France. This arrangement did not continue. Charles V. succeeded the emperor Maximilian, and at once disputed the possession of the Milanese with Francis. In 1522 the imperialists entered Milan and proclaimed Francesco Sforza (son of Lodovico). Francesco died in 1535, and with him ended the house of Sforza. From this date till the War of the Spanish Succession (1714) Milan was a dependency of the Spanish crown. At the close of that war it was handed over to Austria; and under Austria it remained till the Napoleonic campaign of 1796. For the results of that campaign, and for the history of Italian progress towards independence, in which Milan played a prominent part by opening the revolution of 1848, with the inscription of the Cinque Giornate (March 17-22), by which the Austrians were driven out; the reader is referred to the article ITALY.

The Lombard campaign of 1859, with the battles of Solferino and Magenta, finally made Milan a part of the kingdom of Italy.

LITERATURE.—Pietro Verri, Storia di Milano; Corin, Storia di Milano; Canto, Illustrazione grande del Lombardo Veneto; the Milanese chronicles in Muratori's Rer. Ital. scriptores; Sismondi, Italia Repubblica; Ferrari, Storia d'Italia; Litta, Famiglie celebri, s. s. Torriani, Visconti, Sforza, Muratori, Annali d'Italia; Hallam, History of the Middle Ages; and Mediolanum (4 vols., 1881); L. Beltrami, Il Castello di Milano (Milan, 1856); N. de L. de Vigne, Archivio della Guida Milano; (Milan, 1864); F. Malagasci Valeri, Milano, 2 vols. (Bergamo, 1906); and C. M. Ady, A History of Milan under the Sforza (1907).

MILANESI, GAETANO (1813-1895), Italian scholar and writer on the history of art, was born at Siena, where he studied law, and in 1838 he obtained an appointment in the public library. In 1856 he was elected member of the Accademia della Crusca, in which capacity he took part in the compilation of its famous but still unfinished dictionary, and two years later was appointed assistant keeper of the Tuscan archives, in Florence; then he took charge of the famous Medici archives, where he collected a vast body of material on the history of Italian art, not all of which is yet published. In 1889 he became director of the archives, but retired in 1892, and died three years later. His most important publication is his edition of Vasari's works in nine volumes, with copious and valuable notes (Florence, 1878-1885). Of his other writings the following may be mentioned: Il diario inedito di Alessandro Sassiini (in the Archivio storico Italiano, 1842); Documenti per la storia dell' arte senese, 3 vols. (Siena, 1854-1856) and Discorsi sulla storia civile ed artistica di Siena (Siena, 1892). He also edited a number of Italian classics.

See E. Ridolfi's article in the Nuova antologia (May 15, 1893); and A. Virgili's article in the Atti della regia Accademia della Crusca (Florence, 1896).

MILAN OBRENOVICH IV. (1854-1901), king of Servia, was born on the 22nd of August 1854, at Jassy. He was the grand-nephew of the famous Milosh, whose brother Jefrem (d. 1836) had a son, Milosh (1829-1861), who married Maria Katardă, a Moldavian. Milan was their son. While still very young, he lost both his parents, and was adopted by his cousin, Michael Obrenovich, who returned to Servia on the expulsion of the Karageorgieviches in 1858 and became ruling prince on behalf of his family. His first claim to the crown was his that of a prince. Young Michael Milan was educated in Paris, at the Lycée Louis-le-Grand, where he displayed considerable precocity, but he was only fourteen years of age when in 1868 his cousin was assassinated and he succeeded to the throne under a regency. In 1872 he was declared of age, and taking the reins of government into his own hands, soon manifested great intellectual power, coupled with a passionate headstrong character. Eugene Schuyler, who saw him about this time, found him "a very remarkable young man—a singularly intelligent and well-informed." By a careful balancing of the two years of Servia with Austria, with a judicious leaning towards the former, Prince Milan was enabled in 1878, at the end of the Turkish War, to induce the Porte to acknowledge his independence, and was proclaimed king in 1882. (The history of his reign is told in detail under SERVIA.) Acting under Austrian influence, King Milan devoted all his energies to the improvement of means of communication and the development of natural resources, but the cost, which was unduly increased by reckless extravagance, led to proportionately heavy taxation. This, coupled with increased military service, rendered King Milan and the Austrian party most unpopular; during the reign of the Servians in the war against Bulgaria, 1885-86. In 1883 (Sept.) the union of Rumelia and Bulgaria caused widespread agitation in Servia, and Milan precipitately declared war upon his kinsman Prince Alexander on the 15th of November. After
a short but decisive campaign, the Servians were utterly routed at the battle of Strumitsa and Pirat, and Milán's throne was only saved by the direct intervention of Austria. Domestic difficulties now arose which rapidly assumed a political significance. In October 1875 King Milan had married Natalie, the sixteen-years-old daughter of Peter Ivanovich Ketchko, a Moldavian Boyar, who was a colonel in the Russian army, and whose wife, Pulcheria, was by birth Princess Sturdza. A son, Alexander, was born in 1876, but the king and queen showed signs of friction. Milan was anything but a faithful husband. Queen Natalie was greatly influenced by Russian sympathies, and the couple, ill-assorted both morally and politically, separated in 1886, when the queen withdrew from the kingdom, taking with her the young prince, Alexander, afterwards king, then ten years of age. While she was residing at Wiesbaden in 1888, King Milan succeeded in recovering the crown prince, whom he undertook to educate; and in reply to the queen's remonstrances, he exerted considerable pressure upon the metropolitan, and procured a divorce, which was afterwards annulled as illegal. King Milan now seemed master of the situation, and on the 3rd of January 1889 he promulgated a new constitution. This new declaration is the existing one of 1869. Two months later (March 6) he suddenly abdicated in favour of his son, a step for which no satisfactory reason was assigned, and settled as a private individual in Paris. In February 1891 a Radical ministry was formed, Queen Natalie and the ex-metropolitan Michael returned to Belgrade, and Austrian influence began to give way to Russian Fear of a revolution and of King Milan's return led to a compromise, by which in May 1891 the queen was expelled, and Milan was allowed a million francs from the civil list, on condition of not returning to Servia during his son's minority. Milan in March 1892 renounced all his rights, and even his Servian nationality. The situation altered, however, after the young King Alexander in April 1893 had effected his coup d'etat and taken the reins of government into his hands. Servian politics began to grow more complicated, and Russian intrigue was rife. In January 1894 Milan suddenly appeared at Belgrade, and his son gladly availed himself of his experience and advice. On the 29th of April a royal decree reinstated Milan and Natalie, who in the meantime had become ostensibly reconciled, in their position as members of the royal family. On the 21st of May the constitution of 1869 was restored, and Milan continued to exercise considerable influence over his son. The queen, who had been residing chiefly at Biarritz, returned to Belgrade in May 1895, after four years' absence, and was greeted by the populace with great enthusiasm. In 1897 Milan was appointed commander-in-chief of the Servian army. In this capacity he did some of the best work of his life, and his success in improving the Servian military system was very marked. His relations with the young king also remained good, and for a time it seemed as though all Russian intrigues were being checked. The good relations between father and son were interrupted, however, by the latter's marriage in July 1900. Milan violently opposed the match, and resigned his post as commander-in-chief; and the young king banished him from Servia and threw himself into the arms of Russia. Milan retired to Vienna, and there he died unexpectedly on the 11th of February 1901. Milan was an able, though headstrong man, but he lived a scandalously irregular life, and was devoid of moral principle. In considering his relations with his young son, it must be remembered that in the dynastic and political condition of Servia natural feeling was inevitably subordinated in Milan to other considerations.

H. Cn."

MILA Y FONTANALS, MANUEL (1818-1884), Spanish scholar, born at Villafranca del Panadés, near Barcelona, on the 4th of May 1818, was educated first at Barcelona, and afterwards at the university of Cervera. In 1845 he became professor of literature at the university of Barcelona, and held this post till his death at Villafranca del Panadés on the 16th of July 1884. The type of the scholarly recluse, Milà y Fontanals was almost unknown outside the walls of the university till 1859, when he was appointed president of the juegos florales at Barcelona.

On the publication of his treatise, De Los trovadores en España (1866), his merits became more generally recognized, and his monograph, De La poesía herético-popular castellana (1873) revealed him to foreign scholars as a master of scientific method.

MILAZZO, a seaport on the north coast of Sicily, in the province ofMessina, 22 m. W. of Messina by rail. Pop. (1901), 16,422. It is mainly built on the low isthmus of a peninsula, which stretches some 3 m. farther north and forms a good harbour: but the old town, which contains a castle, mainly the work of Charles V., lies on a hill above. Milazzo is the ancient Myla, an outpost of Zancle, occupied before 648 B.C., perhaps as early as 716 B.C. (E. A. Freeman, History of Sicily, I., pp. 395, 587). It was taken by the Athenians in 426 B.C. The people of Rhegium planted here the exiles from Naxos and Catana in 355 B.C. as a counterpoise to Dionysius' foundation of Tyndaris; but Dionysius soon took it. In the bay Duillus won the first Roman naval victory over the Carthaginians (260 B.C.).

MILDENHALL, a market town in the Stowmarket parliamentary division of Suffolk, England, 76½ m. N.N.E. from London by rail, the north-western terminus of the East Suffolk railway from Cambridge. Pop. (1901), 3567. It lies on the edge of Mildenhall Fen, the great Fen district stretching northward and westward from here. The church of St Andrew has an Early English chancel with fine east window and chancel arch. The remainder is principally Perpendicular with a magnificent carved oak roof, ornate north porch and lofty tower with fan tracery within. There is a wooden market cross of the 15th century; the manor house is a picturesque gabled building of the 17th century, and there is a modern public hall. Flour milling is an industry. The drainage of Roman remains indicates a small settlement.

MILDEW (O. Eng. meldewe or mildew, explained as "meal-dew," cf. Ger. Mehldau, with more probability, as "honey-dew," Goth. melith, honey, cf. Lat. mel, Gr. μέλι), a popular name given to various minute fungi from their appearance, and from the sudden, dew-like manner of their occurrence. Like many other popular names of plants, it is used to denote different species which possess very small botanical affinity. The term is applied, not only to species belonging to various systematic groups, but also to such as follow different modes of life. The corn-mildew, the hop-mildew and the vine-mildew are, for example, parasitic on living plants, and the mildews of damp linen and of paper are saprophytes (Gr. οροφές, rotten), that is, they subsist on matter which is already dead. As regards mildews in general, the conditions of life and growth are mainly suitable nutrition and dampness accompanied by a high temperature. The life history of the same species of mildew frequently covers two or more generations, and these are often passed on hosts of different kinds. In some cases again the same generation confines its attack to the same kind of host, while in others the same generation grows on various hosts (see Fungi; Hop; and Wheat).

MILES, NELSON APPLETON (1830— ), American soldier, was born in Westminster, Massachusetts, on the 8th of August 1830. He was engaged in mercantile pursuits in Boston when the Civil War began, and he entered the army in September 1861 as a lieutenant in the 22nd Massachusetts volunteer infantry. He served with distinction in the Peninsula campaign, and at Antietam, Fredericksburg and Chancellorville, where he received a wound which incapacitated him up to the opening of Grant's Virginia campaign of 1864. He had been commissioned in September 1861 colonel of the 61st New York volunteers, commanded a brigade at the Wilderness and Spottsylvania, and in May 1864 was rewarded for his gallant leadership by the grade of brigadier-general of volunteers. He fought in the Cold Harbor and Petersburg operations in 1864-65, was brevetted major-general of volunteers for his conduct at Reams Station, and at the close of the war was in temporary command of an army corps. In July 1866 he was made colonel of a regular infantry regiment, and in 1867 he was brevetted brigadier general in the regular army for his services at Chancellorville and major-general for his services at Spottsylvania. He was promoted to be brigadier-general U.S.A. (Dec. 1880), and to be
MILETUS—MILFORD

major-general (April 1859), and in 1869 succeeded General John McA. Schofield as commanding general of the United States army. He was conspicuously successful (1869-1866) in dealing with Indian outbreaks, fighting the Cheyennes. Back in Europe, Comanche on Llano Estacado (1875) and the Sioux in Montana (1876), capturing the Nez Percés under Chief Joseph (1877), and defeating the Chiricahua Apaches under Geronimo (1886), and he commanded the United States troops sent to Chicago during the railway riots in 1894. He was in nominal direction of military operations during the war with Spain in 1898, though his personal share of the operations was confined to directing the almost unopposed Porto Rico expedition. He was raised to the rank of major-general on June 6, 1900, and retired from active service in August 1903. In 1895, he was appointed aide-de-camp and chief-of-staff under Governor William L. Douglas in Massachusetts. He wrote Personal Recollections (1860), Military Europe (1868) and Observations Abroad (1899).

MILETUS (mod. Palatia), an ancient city of Asia Minor, on the southern shore of the Latmic Gulf near the mouth of the Maeander. Before the Ionic migration it was inhabited by Carians (Hlud. i. 879; Herod. i. 149, and pottery, found by Th. Wiegand on the spot proves that the site was inhabited, and had relations with the Aegean world, see latest Minoan age. The Greek settlers from Pylos under Nestor, established here in 1200 B.C. to have built all the men in the old city, and built for themselves a new one on the coast. Miletus occupied a very favourable situation at the mouth of the rich valley of the Maeander, and was the natural outlet for the trade of southern Phrygia (Hippopax, Fr. 45). It had four harbours, of considerable size, and its power extended inland for some distance up the valley of the Maeander, and along the coast to the south, where it founded the city of Iasus. Its enterprise extended to Egypt, where it had much to do with the settlement of Naukratis (q.v.). Very little "Naukratis" pottery, however, was found on the site by Wiegand, and only in the Athena temple. The Black Sea trade, however, was the greatest source of wealth to the Ionian cities. Miletus, like the rest, turned its attention chiefly to the north, and succeeded in almost monopolizing the traffic. Along the Hellespont, the Propontis and the Black Sea coasts it founded more than sixty cities—among them Abydos, Cyzicus, Sinope, Dioscurias, Panticapaeum and Olbia. All these cities were founded before the middle of the 7th century; and before 500 B.C. Miletus was decidedly the greatest Greek city. During the time when the enterprise of the seafaring population raised Miletus to such power and wealth it was the focus of all Greece, though the analogy of all Greek cities, and some casual statements in later writers, suggest that the usual struggles took place between oligarchy and democracy, and that tyrants sometimes raised themselves to supreme power. Miletus was equally distinguished at this early time as a seat of literature. The Ionian epic and lyric poetry indeed had its home farther north; philosophy and history were more akin to the practical race of Miletus, and Thales, Anaximander, Anaximenes and Hecataeus all belonged to this city. The poet Timotheus and the famous Aspasius were also natives. The three Ionian cities of Caria, Miletus, Myus and Priene—spoke a peculiar dial of Ionic.

The Mermnad kings of Lydia found in Miletus their strongest adversary. War was carried on for many years, till Alyattes III. concluded a peace with Thrasybulus, tyrant of Miletus; the Milesians afterwards seem to have acknowledged peaceably the rule of Croesus. On the Persian conquest Miletus passed under a new master; it headed the Ionian revolt of 500 B.C. and was taken by storm after the battle of Lade (see IONIA). Dariskus massacred most of the inhabitants, transported the rest to Ampe at the mouth of the Tigris, and gave up the city to the Carians. This disaster was long remembered in Greece and made the theme of a tragedy by Phrynichus. Henceforth the history of Miletus has no special interest. It revived indeed when the Persians were expelled from the coast in 479 B.C., became a member of the Delian League (q.v.), revolted to Sparta in 412, passed into Carian hands, and opposed Alexander on his southward march, succumbing only to a siege in form (334 B.C.). It was a town of commercial importance throughout the Graeco-Roman period, and received special attention from Trajan. Its harbours, once protected by Lade and the other Tragassaean islands, were gradually silted up by the Maeander, and Lade is now a hill 10 miles from the coast. Ephesus took its place as the great Ionian harbour in Hellenistic and Roman times. Miletus became the seat of a Christian bishopric and was strengthened by a Byzantine castle (κάστρω τοῦ Πελατίου) built above the theatre; but its decay was inevitable, and its site is now a marsh.

Since 1899 Miletus has been the scene of extensive excavations directed by Dr Th. Wiegand for the Berlin Academy. The ruins lie on a slight eminence by a hillock projecting north-east to a bend of the Maeander. On the north are well-preserved remains of Greek times on the site of an older Greek building. When complete it had 54 rows of seats. It was as large as any theatre in Asia Minor, and is still imposing, the auditorium, though drained of the upper seats, still retaining its upper ranks and colonnade, rising nearly 100 ft. Cyriac of Ancona described the building as practically complete in his day (1446). The front is over 150 yds. long. East of this was the ancient north harbour, now silted up, and on the hillside above stood a large heroon of Hellenistic time remarkable for being, like the tomb of Brasidas at Amphipolis, within the walls. South of the harbour and near the ancient industrial district were large magazines of Doric style. South of these were lie a vast Osirian temenos of Tithes, and a senate-house of theatrical form. On the east opens a great hall surrounded by porticoes and enclosing a high altar of Artemis. There were also unopposed the agorai, groups of market-halls of various sizes in the latest Minoan period. west from the north harbour to the Didyma Gate in the wall, which runs across the peninsular and encloses the site of the ancient palace and the peninsula and was rebuilt by Trajan, when he undertook to raise the city. On the western and streets cross this at right angles in the geometric Hellenistic manner. A Sacred Way lined with tombs, led to Didyma. Two temples have been discovered by Dr Wiegand, one, on the south-east, being a large sanctuary of Apollo Delphinus with triple colonnade enclosing a court with central tripod. This seems to have been the chief temple of the city and the place where public records, treaties, &c., were enshrined. The other temple, an archaic sanctuary of Athena, lies west of the stadium.

See O. Rayet and A. Thomas, Milet et le golfe Latique (1877); Th. Wiegand, "Vorläufige Ausgrabungen in Milet," in Sitzungsberichte der Berliner Akademie (1900, 1901); A. von Sails, "Die Ausgrabungen in Milet und Didyma" in Neue Jahrb. f. d. k. Alt., xxv. 1910. (D. G. H.)

MILFORD, a township of New Haven county, Connecticut, U.S.A., on Long Island Sound, separated from the township of Stratford on the W. by the Housatonic river, and about 10 m. S.W. of New Haven. Pop. (1890), 3511; (1900), 3738, including 541 foreign-born and 173 negroes; (1910), 4366. Area, about 16 m. See Woodmont (incorporated as a borough in 1903), Pond Point, Bay View, Fort Trumbull Beach (where a fortification, named Fort Trumbull, was erected in 1776), Myrtle Beach, Meadow's End, Walnut Beach and Milford Point. The township is traversed by the Wepowaug river, which here empties into the Sound. Milford is a typical old New England town, and many of the permanent inhabitants are descendants from the first settlers. The burying-ground includes the tomb of Robert Treat (1622-1710), commander of the Connecticut troops in King Philip's War, leader of the company that founded Newark, New Jersey, governor of Connecticut (from 1683 to 1698) at the time its charter was demanded by Governor Andros in 1686-1687, and deputy-governor in 1676-1683 and 1693-1708; and also that of Jonathan Law (1674-1751), governor of Connecticut from 1742 to 1751. Spanning the Wepowaug river near a gort and not far from its mouth is a granite bridge and tower, built, as a memorial to the first settlers, in 1899, in connexion with the celebration of the 300th anniversary of the founding of the town. Milford has a beautiful green of about four acres, containing a soldiers' monument. It has also the Taylor Library (founded in 1894), and along the Sound are many summer residences. Named after Milford, England, it was founded in 1639 by Rev. Peter Prudden and his followers from New Haven and Wethersfield. The land was purchased from the Indians for 6 coats, 10 blankets, 1 kettle, 12 hatchets, 12 hoes,
24 knives and 12 small mirrors. A "church-state" was immediately organized after the model of that of New Haven, but two or three years later the town bestowed suffrage on six of its inhabitants who were not church members. These citizens were an obstacle to the town's admission to the New Haven Jurisdiction, which was formed in 1643, but in the following year a compromise was effected and Milford was admitted on condition that, in the future, suffrage should be granted only to church members and that none of the objectionable six should be elected to any office of the Jurisdiction. In 1664, Milford, with the other members of the Jurisdiction, was absorbed by Connecticut; this caused considerable dissatisfaction and some of the inhabitants under the lead of Robert Treat removed to New Jersey and assisted in the founding of Newark. The regicides Whalley and Goffe were concealed in Milford from 1661 to 1664.

MILFORD, a township of Worcester county, Massachusetts, U.S.A., about 16 m. S.E. of Worcester. Pop. (1800) 8780; (1900) 13,976, of whom 3342 were foreign-born; (1910 census) 13,551. Within its area of about 15 sq. m. are a large rural population and the village of Milford, on the Charles river, about 33 m. S.W. of Boston, served by the Boston & Albany, the New York, New Haven & Hartford and the Grafton & Upton railways (the last named having its passenger department operated by electricity and its freight by steam, and connecting Milford with North Grafton), and by inter-urban electric lines. The village has a memorial hall, housing the public library, and in the township there is an excellent hospital, the gift of Eben Seely. The village is a stopping point for an agricultural and manufacturing district. In 1905 the value of the township's factory products was $3,306,504 (32-8% more than in 1900). The most important manufactures are boots and shoes; the industry was established in 1795, and for many years the special product was brogans for Southern negroes. In 1908 there were 12 large granite quarries in the township (north and north-east of the village). Milford granite is the typical stone of an area reaching into Rhode Island south of the southern boundary of Providence county; it is a biotite granite of post-Cambrian age, is generally pinkish-gray in colour (owing to the large proportion of feldspar among its constituents), and is widely used for building purposes. The township was the east precinct of Mendon until 1780, when it was incorporated; in 1835 parts of Holliston and Hopkinton were annexed; in 1886 a part was separated as Hopedale.

MILFORD HAVEN, a market town, seaport, urban district and contributory parish, and borough of Pembroke
docks, situated on the north shore of the celebrated harbour of the same name. Pop. (1901), 5102, including the adjacent village of Hakin. Milford Haven is the terminus of a branch-line of the South Wales section of the Great Western railway. The town possesses a pier and important dock accommodation, including a graving-dock 600 ft. long, and is the centre of a valuable and increasing fishing industry. The promenade of Milford Haven commands a fine view of the broad expanse of the Haven with its various towns and forts.

The present town of Milford Haven, originally a hamlet in the parish of Steynton, is of modern growth, and was first called into existence by the exertions of the Hon. R. F. Greville, nephew of Sir William Hamilton, who in 1790 laid out a town on this spot, the advantages of which as a convenient port for the Irish traffic he clearly recognized. In the opening years of the 19th century a royal dockyard was established here, but in 1814 dockyard and arsenal were removed to Paterchurch near Pembroke. The growth of the town was further checked twenty years later by the development of Neyland, or New Milford, further east in the Haven, whether the Irish packet service was transferred; but towards the close of the 19th century the town recovered much of its former prosperity. The importance of the place is wholly due to its excellent situation on the splendid-land-locked harbour, which is here 2 m. broad.

Milford Haven itself, designated by the Welsh Aberdaugleddau, as the estuary of the united East and West Cleddy rivers, has played an important part on several occasions in the course of history. Throughout Plantagenet times it formed the chief point of embarkation for Ireland. It was from Milford Haven that Henry IV set sail for the conquest of Ireland in 1217, and to its harbour he made his return journey. In 1390 Richard II landed at Milford Haven from Ireland, shortly before his surrender to Henry of Lancaster, afterwards Henry IV, in whose reign a French fleet with 12,000 men on board sailed to the Haven and disembarked with the object of assisting the rebellion of Owen Glendower. In 1485 Henry, earl of Richmond, disembarked here on his return from France, and was welcomed on landing by Sir Rhys ap Thomas and many of the chivalry of Wales. In 1588 the leading persons of Pembroke, with Bishop Anthony Rudd of St David's at their head, petitioned Queen Elizabeth to fortify the Haven against the projected Spanish invasion, upon which the block-houses of Dale and Nangle at either side of the mouth of the harbour were accordingly erected. During the 19th century numerous forts have been constructed for the protection of the Haven and of the royal dockyard at Pembroke Dock.

MILICZ, or MILITSCR (d. 1374), Bohemian divine, was the most influential among those preachers and writers in Moravia and Bohemia who, during the 14th century, in a certain sense paved the way for the reforming activity of Huss. The date of his birth is not certain, but it was in holy-days, 1260. He was attached to the court of the emperor Charles IV., whom he accompanied into Germany in that year, and about the same time also held a canony in the cathedral of Prague along with the dignity of archdeacon. About 1363 he resigned all his appointments that he might become a preacher pure and simple; he addressed scholars in Latin, and (an innovation) the laity in their native Czech, or in German, which he learnt for the purpose. He was conspicuous for his apostolic poverty and soon roused the enmity of the mendicant friars. The success of his labours made itself apparent in the way in which he transformed the notorious "Benati" street of Prague into a benevolent institution, "Jerusalem." As he viewed the evils inside and outside the church in the light of Scripture, the conviction grew in his mind that the "abomination of desolation" was now seen in the temple of God, and that antichrist had come, and in 1367 he went to Rome (where Urban V. was expected from Avignon) to expound these views. He affixed to the gate of St Peter's a placard announcing his sermon, but before he could deliver it was thrown into prison by the Inquisition. Urban, however, on his arrival, ordered his release, whereupon he returned to Prague, and from 1360 to 1372 preached daily in the Tyn Church there. In the latter year the clergy of the diocese complained of him in twelve articles to the papal court at Avignon, whether he was summoned in Lent 1374, and where he died in the same year, not long after being declared innocent and authorized to preach before the assembly of cardinals. He was the author of a Libellus de Antichristo, written in prison at Rome, a series of Postilla and Leonciones quadragesimales in Latin, and a similar series of Postilis (devotional tracts) in Czech.

MILITARY FRONTIER (Ger. Militärgrenze, Slav. Granitza), a narrow strip of Austrian-Hungarian territory stretching along the borders of Turkey, which had for centuries a peculiar military organization, and from 1849 to 1875 constituted a crown-land. As a separate division of the monarchy it owed its existence to the necessity of maintaining during the 16th and 17th centuries a strong line of defence against the invasions of the Turks, and may be said to have had its origin with the establishment of the captaincy of Zengg (a coast town about 35 m. south-east of Fiume) by Matthias Corvinus and the introduction of Uskoks (q.v.) into Croatia. By the close of the 17th century there were three frontier "generalates"—Carlstadt, Karakinds and Petrinia.
or Petrinja (the last also called the Banal). After the defeat of the Turkish power by Prince Eugene it was proposed to abolish the military constitution of the frontier, but the change was successfully resisted by the inhabitants of the districts; in fact a new Slavonian frontier district was established in 1702, and Maria Theresa extended the organization to the march-lands of Transylvania (the Szekler frontier in 1764, the Wallachian in 1760).

As a reward for the service it rendered the government in the suppression of the Hungarian insurrection in 1848, the Military Frontier was erected in 1849 into a crown-land, with a total area of 1,518 sq. m. and a population of 1,200,593. In 1852 the Transylvanian portion (1,717 sq. m.) was incorporated with the rest of Transylvania; and in 1871 effect was given to the imperial decree of 1869 by which the districts of the Warsadins regiments (St George and the Cross) and the towns of Zeng, Belovar, Ivanic, &c., were "provincialized" or incorporated with the Croatian-Slavonian crown-land. In 1872 the Banat regiments followed suit; and in 1873 the old military organization was abolished in the rest of the frontier. Not till 1881, however, were the Croatian-Slavonian march-lands completely merged in the kingdoms to which they naturally belonged.

The social aspect of the military frontier régime is interesting. The sizarz system under which public revenue is partly raised in fact, in the commonwealth, for the purposes of the military department, is also characteristic. Watch-towers with wooden roofers and the beacons which flashed the alarm along the whole frontier in a few hours are still features in the landscape.

Military Law, "the law which governs the soldier in peace and in war, at home and abroad. At all times and in all places the conduct of officers and soldiers as such is regulated by military law." The above is the definition as given in the opening chapter of the Manual of Military Law, which is issued under the authority of the English War Office, and which is the textbook used by all English courts martial. The definition is, however, somewhat too wide, as the British system does not exclude in time of peace the action of the civil courts. In time of peace all persons who belong to the military class in most European continental countries are judged by military law and by military courts. There is also in most continental countries an intermediate stage between war and peace, known as in Etat de siege, which may be declared for a fixed period for a district, or even a city, by reason of domestic insurrection or the presence of an enemy. It requires legislative enactment. Thirdly comes a state of war, when the military authorities are supreme; and whilst they can call upon the civil powers for such aid as is necessary they are in all respects independent. This is a brief summary of the system of military law that prevails in most countries of the continent. The cardinal point of difference between the British and the continental systems lies in the fact that in the United Kingdom the soldier is not only a soldier, but a citizen also; and although he may be tried for civil offences by a military tribunal, the power is not exercised in all cases. Thus treason, treason-felony, murder, manslaughter, rape, are brought before a civil court in times of peace, if the offence is committed in the United Kingdom, or if it is committed anywhere else in the king's dominions, except Gibraltar, or within a hundred miles from a place in which the Crown is resident. A person can be tried by a civil court.

Minor civil offences, when not committed within military lines, or when the person affected by the offence is a civilian, or when it is a case for a jury, or when intricate questions of law may arise, may also be brought before a civil tribunal. But an offence, of whatever nature, committed on active service would be brought before a military tribunal.

The military law of England in early times existed, like the forces to which it applied, in a period of war only. Troops were raised for a particular service, and were disbanded upon the cessation of hostilities. The crown, of its mere准备好 laws known as Articles of War, for the government and discipline of the while thus embodied and serving. Except for the punishment of desertion, which offence was made a felony by statute in the reign of Henry VI., these ordinances or Articles of War remained almost the sole authority for the enforcement of discipline until 1869, when the first Mutiny Act was passed and the military forces of the crown were brought under the direct control of parliament. Even the Parliamentary forces in the time of Charles I. and Cromwell were governed, not by an act of the legislature, but by an ordinance similar to those issued by the king and authorized by an ordinance of the Lords and Commons, exercising in that respect the sovereign prerogative. This power of law-making by prerogative was, however, held to be applicable during a state of actual war only, and attempts to exercise it in time of peace were ineffectual. Subject to this limitation it existed for considerably more than a century after the passing of the first Mutiny Act. From 1689 to 1803, although in peace time the Mutiny Act was occasionally suffered to expire, a statutory power was given to the crown to make Articles of War to operate in the colonies and elsewhere beyond the seas in the same manner as those made by prerogative. In consequence of the rebellion, this power was created in respect of the forces in the kingdom. But these enactments were apart from and in no respect affected the principle acknowledged all this time—that the crown of its mere prerogative could make laws for the government of the army in foreign countries in time of war. The Mutiny Act of 1803 effected a great constitutional change in this respect: the power of the crown to make any Articles of War became altogether statutory, and the prerogative merged in the act of parliament. So matters remained till the year 1879, when the last Mutiny Act was passed, and the Articles of War were promulgated. The Mutiny Act legislated for offences in respect of which death or penal servitude could be awarded, and the Articles of War, while repeating those provisions of the act, constituted the direct authority for dealing with offences for which imprisonment was the maximum punishment as well as with many matters relating to trial and procedure. The act and the articles were found not to harmonize in all respects. Their general arrangement was faulty, and their language sometimes obscure. In 1869 a royal commission was appointed to report as to whether the Articles of War should be revised and made intelligible. In 1878 a committee of the House of Commons endorsed this view and made certain recommendations as to the way in which the task should be performed. In 1879 the government submitted to parliament and passed into law a measure consolidating in one act both the Mutiny Act and the Articles of War, and amending their provisions in certain important respects. This measure was called the "Army Discipline and Regulation Act 1879." After one or two years' experience of its working it also was found capable of improvement, and in its turn superseded by the Army Act 1881, which now forms the foundation of the military law of England. It contains a proviso saving the right of the crown to make Articles of War, but in such a manner as render the power in effect a nullity; for it enacts that no crime made punishable by the act shall be otherwise punishable by such articles. As the punishment of every conceivable offence is provided for by the act, any articles made therein can be no more than an empty formality having no practical effect. Thus the history of English military law up to 1879 may be divided into three periods, each having a distinct constitutional aspect: (1) that prior to 1689, when the army, so far as regards regulation, was governed by the will of the sovereign; (2) that between 1689 and 1803, when the army, being regarded as so many personal retainers of the sovereign rather than servants of the state, was mainly governed by the will of the sovereign; (3) that between 1879 and 1880, when, the army, being recognized as a permanent force, was governed within the realm by statute and without it by the prerogative of the crown; and (4) that from 1803 to 1879, when it was governed either directly by statute or by the sovereign under
an authority derived from and defined and limited by statute. Although in 1879 the power of making Articles of War became in effect altogether inoperative, the sovereign was empowered to make rules of procedure, having the force of law, which regulate the administration of the act in many matters formerly dealt with by the Articles of War. These rules, however, must not be inconsistent with the provisions of the Army Act itself, and must be laid before parliament immediately after they are made. Thus in 1879, the government's discipline of the army became for the first time completely subject either to the direct action or the close supervision of parliament.

A further notable change took place at the same time. The Mutiny Act had been brought into force on each occasion for one year only, in compliance with the constitutional theory that the maintenance of a standing army in time of peace, unless with the consent of parliament, is against law. Each session therefore the text of the act had to be passed through both Houses clause by clause, and line by line. The Army Act, on the other hand, is a fixed permanent code. But constitutional traditions are fully respected by the insertion in it of a section providing that it shall come into force only by virtue of an annual act of parliament. This annual act recites the illegality of a standing army in time of peace unless with the consent of parliament, and the necessity nevertheless of maintaining a certain number of land forces (exclusive of those serving in India) and a body of royal marine forces on shore, and of keeping them in exact discipline, and it brings into force the Army Act for one year.

Military law is thus chiefly to be found in the Army Act and the rules of procedure made thereunder, the Militia Acts, the Reserve Forces Acts and the Volunteer Acts, together with certain acts relating to the yeomanry, the Territorial and Reserve Forces Act 1907, and various royal warrants and regulations. In the Army (Annual) Act 1906 important amendments were made to the Army Act for the purpose of preventing soldiers convicted of offences against discipline under the act, and not discharged with ignominy, being subjected to the stigma attaching to imprisonment. This was effected by creating a new punishment, termed detention barracks. This change, while principally one of nomenclature, removed an undoubted grievance. The Army Act itself, however, the chief authority. Although the complaint has been sometimes made, and not without a certain amount of reason, that it does not accomplish much that it might in point of brevity, simplicity and clearness of expression, it is a very comprehensive piece of legislation, and shows some distinct improvements upon the old Mutiny Acts and Articles of War.

When a person subject to military law commits an offence he is taken into military custody, which means either arrest in his own quarters or confinement. He must without unnecessary delay be brought before his commanding officer, who upon investigating the case may dismiss the charge, if in his discretion he thinks it ought not to be proceeded with, or may take steps to bring the offender before a court martial. Where the offender is not an officer he may dispose of the case summarily, the limit of his power in this respect being seven days' imprisonment with hard labour not exceeding 10s. for drunkenness, certain deductions from pay, confinement to barracks for twenty-eight days, this involving severe extra drills, deprivations, and other minor punishments. Where the offence is absence without leave for a period exceeding seven days, the commanding officer may award a day's imprisonment in respect of each day of such absence up to twenty-one. It is only in the case of the imprisonment exceeding seven days that the evidence before the commanding officer is summarily heard. The commanding officer is enjoined by regulation not to punish summarily the more serious kinds of offences, but his legal jurisdiction in this respect is without limit as regards any soldier brought before him, and where he has dealt summarily with a case the accused is free from any other liability in respect of the offence thus disposed of. In any instance where the commanding officer has summarily awarded imprisonment, fine or deduction from pay, the accused may claim a district court martial instead of submitting to the award.

Ordinary courts martial are of three kinds, viz. (1) a regimental court martial, usually convened and confirmed by the commanding officer of the regiment or detachment, presided over by an officer not ranking in the rank of captain, composed of at least three officers of the regiment or detachment with not less than one year's service, and having a maximum power of punishment of forty-two days' detention; (2) a district court martial, usually convened by a general officer having authority to do so, consisting of not less than three officers, each with not less than two years' service, and having a maximum power of punishment of two years' imprisonment; (3) a general court martial, the only tribunal having authority to try a commissioned officer, and with a power of punishment extending to death or penal servitude, for offences for which these penalties are authorized by statute; it constitutes in the United Kingdom, India, Malta and Gibraltar and of five elsewhere, each of whom must have had over three years' service, five being not under the rank of captain. There is another kind of tribunal, viz. a field general court martial. It is convened (i) by any officer in command of a detachment or portion of troops beyond the seas when not on active service, or by any officer in immediate command of a body of forces on active service where it appears to him on complaint or otherwise that a person subject to military law has committed an offence. The officer must be satisfied that the act is an offence; he must then order the accused to appear before him for trial as a court martial to try the person by an ordinary court martial. The quorum of the court is three, if consistent with military exigencies, and each member must have held a commission for not less than a year. The quorum may be reduced when the public service requires it. The procedure of ordinary courts martial is observed as far as possible, and the proceedings always should be in writing when possible. But in the circumstances in which these courts are assembled, it is not always possible to adhere to the technical rules which obtain in the ordinary tribunals, although the broad principles are not violated. The evidence on a field general court martial is taken orally. The prisoner is examined by the witnesses for his defence, and may call any available witnesses for his defence. The prisoner is allowed to address the court in his own behalf.

The Army Act prescribes the maximum punishment which may be inflicted in respect of each offence. That of death is incurred by various acts of treachery or cowardice before the enemy, or by, when not on active service, active service, leaving without orders a guard or post, or when on active service conniving at or being drunk on a post, plundering or committing an offence against the person or property of an inhabitant, intentionally causing false alarm, or deserting. Whether disease or insubordination, the offender also becomes liable to the punishment of death who mutinies or incites to or joins in or connives at a mutiny, who uses or offers violence to or deftantly disobeys the lawful command of his superior officer when in the less than his office. Penal servitude is the maximum punishment for various acts and irregularities upon active service not distinctly of a treacherous or willfully injurious character, for using or offering violence or insubordinate language to a superior, or disobeying a lawful command when upon active service. The same punishment is applicable when not upon active service to a second offence of desertion or fraudulent enlistment (i.e. enlistment under false pretences or for fraudulent purposes) of any person composed of embezzlements of public property, willfully releasing without authority a prisoner or willfully permitting a prisoner to escape, enlisting when previously released from the service with disgrace without disclosing the circumstances of such discharge, or any other offence against the ordinary criminal law of England which is punishable with penal servitude. Imprisonment for two years is the maximum punishment for minor desertions, or for deserting after his commission or for the omission of a parole by a prisoner who was under a committed upon active service would involve death or penal servitude, or offering or threatening violence or insulting language to a superior or disobeying a lawful command, and for the following offences: resisting an officer in the execution of his duty, or failing to obey a command of desertion or attempted desertion or aiding or conniving at desertion, or of fraudulent enlistment, absence without leave, failure to appear for parade, going beyond prescribed bounds, absence from school, making or being a member of an association formed with intent to render a soldier unfit for service, an act of a fraudulent nature, disgraceful conduct of a cruel, indecent or unnatural kind, drunkenness, releasing a prisoner without proper authority or
allowing him to escape, being concerned in the unreasonable detention of a person awaiting trial, escaping or attempting to escape from lawful custody, committing or attempting to commit theft, theft by trick, theft of goods, obtaining money by false pretences, false pretences or fraudulent representations in public documents, making a willfully false accusation against an officer or soldier, making a false confession of a crime or to conceal the truth,柏托one of the prolongation of furlough, misconduct as a witness before a court martial or contempt of such court, giving false evidence on oath, any offence specified in relation to billeting or the impregnation of officers, making a false statement to a question put to him, being concerned in unlawful enlistment, using treasonous or disloyal words regarding the sovereign, disclosing any circumstance, fact or opinion, circumstances of any part of His Majesty's forces so as to produce effects prejudicial to His Majesty's service, fighting or being concerned in or conniving at a duel, attempting suicide, obstructing the civil authorities in the apparatus or custom of the service, desertion, neglect or neglect to the prejudice of good order and military discipline, any offence which if committed in England would be punishable by the law of England. There is another offence which can be committed by officers only, namely "scaring" or "unbecoming the character of an officer and a gentleman." This necessitates cashing, a punishment which in the case of an officer might be suspended or commuted in several other instances. There is also an offence peculiar to, and the result of, commissioned officers, that of striking or ill-treating a soldier or unlawfully detaining his pay. A sentence of cashing as distinguished from that of "unbecoming the character of an officer and a gentleman" is an incapacity to serve the crown again. An officer may be also sentenced to forfeiture of seniority and to reprimand or severe reprimand. A non-commissioned officer may be sentenced to be confined in a county or court martial for a period not exceeding three years or to penal servitude or imprisonment the tribunal also has power to deprive him of his seniority. The Army Council in England, or the court martial, or the court-martial before each proceeding in either case, may also cause a non-commissioned officer to be reduced to a lower grade or the ranks. An acting non-commissioned officer may be ordered by his commanding officer for an offence or for inefficiency or otherwise to return to his permanent grade—in other words, to forfeit his acting rank.

It will have been observed that persons subject to military law are liable to be tried by court martial for offences which if committed in England would be punishable only by the civil courts. The cases of desertion, theft, false pretences, obtaining money by false pretences, and any offence committed in a civil capacity are all cases of military jurisdiction. With the exception of the last, and in the case of a man who is on active service or in a place more than 100 miles from a civil court having jurisdiction to try the offence, with regard to all civil cases, the military district is, if it is coordinate to the ordinary law, and a civilian aggrieved by a soldier in the commission of a criminal offence against his property or person does not forfeit his right to prosecute the soldier as if he were a civilian.

The crime of murder is the only one usually given as a proper opportunity of preparing his defence, of communicating with his witnesses or legal adviser, and of procuring the attendance of his witnesses. Further, if he desires it, a list of the officers commanding to which the court shall be given him. Any officer is disqualified to sit as a member who has convened the court, is the prosecutor or a party to the case, or has the advantage of any knowledge derived from an inquiry into the facts, who is the prisoner's commanding officer, or who has a personal interest in the case. The prisoner may also object to being tried on the ground of bias or prejudice, similarly as a civilian might challenge a juror. The court, having the advantage of the writing out of the evidence, the procedure at a court martial is very much the same as that at an ordinary criminal trial—the introduction of evidence, cross-examination of the witnesses, addresses of the prosecutor and prisoner, and the rules governing the admission or rejection of evidence being nearly identical. At a general court martial, and sometimes at a district court, a judge advocate represents the country and cross-examines the prisoner if he pleads guilty the court finds a verdict accordingly, reads the summary of the evidence, and proceeds to mit in mitigation of punishment, and takes evidence as to character before proceeding to pass sentence. The sentence is that of the court, except where death is awarded, when two-thirds of the members in the case of a general court martial and the whole in that of a field general court martial must concur. When an acquittal upon all the charges takes place the verdict is announced and the accused is released without further proceeding. When the finding is "guilty," evidence as to character is taken, and the court deliberates in private upon the sentence, but a summary of the evidence is read to the prisoner. The sentences are confirmed and promulgated. No conviction or sentence is confirmed and promulgated unless it is thus confirmed by the proper authority. The confirming authority in the case of a regimental court is the commanding officer, in that of a county court martial or district court martial, the courts martial or some officers deriving authority to confirm the findings and sentences of district courts martial, and in that of a general court, if held in the United Kingdom, His Majesty, and if abroad in most cases the general officer commanding. The confirming authority may order the reassembling of the court in order that any question or irregularity may be revised and corrected, but the purpose is not to increase any kind of the prisoner's own discretion and without further reference to the court, refuse confirmation to the whole or any portion of the finding or sentence, and he may mitigate, commute or entirely remit the punishment, or replace any officer, or remove any soldier from the charge of any officer in the army, or order the officer to perform any duty which he is unable to perform.

In addition to confirmation, however, every general or district court martial held out of India has another ordeal to go through. It is reviewed and examined in the office of the judge advocate general, and any illegality that may be disclosed is corrected and the prisoner is relieved of the consequences. To a certain extent a protection against illegality also exists in the case of regimental courts martial in the United Kingdom, for the regiment is laid before the general commanding, by whom any question that might appear to him doubtful would be referred to the adjutant general or the judge advocate general for decision. It is true, however, that in India the virtual protector of any soldier fulfilling duties which are in their nature judicial, is only an adviser. He is not actually a judge in an executive sense, and has no authority directly to interfere with or correct an illegal conviction. In cases the law thus provides no remedy for an officer or soldier who may have been wronged by the finding or sentence of a court martial—for instance, through a verdict not justified by the evidence or through a non-obsequience of the rules and practice prescribed in these tribunals. A person who has suffered injustice may appeal to the king's bench division of the high court of justice. But, speaking generally, that tribunal would not interfere with any proceedings of the courts martial. The virtual protector of an accused person against illegality is the judge advocate general, who personally advises the sovereign and the military authorities that the law shall be complied with (see Judge Advocate General).

The Army Act applies to European officers and soldiers, serving in India, and to the same extent as to the remainder of the service, the articles of India are governed by their own Articles of War, and in the case of civil offences they are dealt with according to the provisions of the Indian penal code. There are judge advocates general for each command in India, and a court martial judge a government the addition more important military centres.

Important changes were made in the system of courts of inquiry by an Army Order of the 29th of February 1902. A court of inquiry is and has been an assembly of officers directed by a commanding officer to collect evidence and report with respect to a transaction into which he cannot conveniently
A special military tribunal in Germany judges the officials attached to the army. Courts of honour exist in Russia, Germany, Bavaria, Württemberg, Austria-Hungary and Spain. Great Britain and the United States have the system of a "court of inquiry." This was only a commission of inquiry, but it is now public, the accused is present, and the witnesses are also present.

Soldiers not on active service, says the Swedish report, should be answerable for infractions of common law under the jurisdiction of the civil courts. All infractions of military order or discipline committed by soldiers, whether on active service or not, should be judged by military courts. In time of war, it is equally admitted, military courts must judge all offences, even offences at common law, committed by soldiers forming part of an army on campaign. The difference lies in regard to offences committed in the course of peace.

In the United States, the general rule, place and time, it depends on the nature of the crime—in the United Kingdom, United States, Sweden, Finland, Holland and Portugal. In Norway a mixed tribunal judges them.

The procedure in military courts differs according to the countries. In some systems (a) the examination and preparation of evidence are confined to a juge d'instruction; (b) in other systems they are confined to a special commission of inquiry; (c) in some countries the judge sits alone, in others he sits with a public prosecutor. This difference in the examination of evidence is held in Norway, Denmark, Germany, Württemberg, Austria-Hungary, Servia, Belgium and Holland. An auditor directes these courts of inquiry. In Russia an officer acts as juge d'instruction; in Italy, Spain, Rumania, Greece and Turkey an officer acts as juge d'instruction.

The proceedings before a court martial are usually public, except in a very small number of countries that offered, morality, compromise, public order, or where publicity is considered injurious to the interests of the service (cases of discipline, according to the case, a number of courts-martial, a number of cases, to which a military jurist is attached, acts as judge and is always a fixed post. This obtains in Sweden, Finland, Austria-Hungary, Switzerland and Portugal.

In Norway, Denmark, Sweden, Finland, Belgium, England, Holland, Germany, Austria, United States, Spain, Württemberg and Switzerland the presiding officer is chosen for the single trial. In other states the military judges are appointed for a certain term, usually six months. The judging of evidence usually takes place on military courts on the continent differs. Seven judges sit in Belgium, Holland, France, Spain, Portugal, Greece, Turkey and Württemberg; three only, in cases of ordinary offences committed by non-commissioned officers and soldiers in Switzerland, Russia, the United Kingdom, United States and Bavaria. In grave cases in the United Kingdom five to nine sit, in Russia, five to thirteen in the United States. In Norway and Denmark, the court is of thirteen up to twenty-five, unless replaced by a commission and military law.

In Norway, Denmark, Sweden, Finland, and Bavaria and other places in Germany, special summary courts martial are held when necessary. Certain forms and legal guarantees are then dispensed with. Such are held in Belgium and Holland "in a town or place in state of siege." La Présidé is a special court of a judge assisted by a registrar, for vagabonds, servants,utters, and with a very limited competence over soldiers who have committed a petty offence, being "in war in France, Rumania and Greece.

The United Kingdom has a summary court martial when the regular court martial cannot be held without injuring the military service. In the United States there are the "field officers' court martial" and "military commission," consisting of three officers. The second is for judging spies and some other matters that escape the jurisdiction of the regular courts martial.

proceedings, but it also prevents the accruing of any disability or forfeiture. The British judge advocate's office has been much strengthened. It now consists of: (1) The judge advocate general (the Hon. Sir Walter Scott, G.C.M.G.); (2) a deputy judge advocate general, who is a trained lawyer; (3) a deputy judge advocate, also a trained lawyer; (4) a military officer of the rank of colonel who has been called to the bar; (5) in Scotland, from 1859, and on a five-years' appointment from 1860, a colonel who has been called to the bar.

In Germany there is no appeal, except for officials attached to the army. In Austria-Hungary the sentence can be lightened by the commander in chief, or by the imperial military council, or by trial by court. In Prussia an appeal is possible in every case except for crimes committed during the first four years of the reign of Frederick William III. In 1908 England, although 1675 not (2) their place in 1848-49 and the military system of the army. The complaint is immediately carried into force, but the person punished can complain to higher military authority. In that case, if the complaint is not admitted, the punishment is enhanced. The complaint may be made by a private soldier. The courts-martial are also a means of appealing against sentences of death, imprisonment, and arrest. Certain special punishments obtain in certain countries—for instance, imprisonment in Greece may be accompanied by a bread-and-water diet; and officers in South Africa may be deprived of all pecuniary remuneration.

In 1908 France took steps to abolish courts-martial in time of peace, all common law offenses to be judged by the ordinary courts, and breaches of military discipline such as rebellion, insubordination, desertsion, and the like by mixed courts composed of civil and military magistrates.

**MILITIA** (Fr. milice, Ger. Miliz, from Lat. miles, soldier, militia, military service), a term used generally for organized forces which are not professional in character and not permanently embodied. All ancient armies, with the exception of the personal guards of their leaders, were militias or national levies, remaining under arms for the war or the campaign and returning to their ordinary occupations at the close of each military episode. Militias such as those of the Greek city-states and that of Rome were of course highly trained to the use of arms; so were the barbarian "nations in arms"; which overcame the professionalized Roman armies of the Empire; and although in the Eastern Empire these new fighting elements were absorbed into a fully organized regular arm, in the West the tribal militia system gradually developed into feudalism. The noble and the knight indeed spent the greater part of their lives in the field and devoted themselves from their youth to the cult of arms, but the feudal tenantry, who were bound to give forty days' war service and no more, and the burghers who, somewhat later, in the history of civilization, formed the efficient garrisons of the walled towns were true militias. The English Yeomanry indeed almost ruled the battlefield.

In the 15th century the introduction of firearms began to weigh down the balance in favour of the professional soldier. Artillery was always the arm of the specialist. The development of infantry, "fire-power," with the early arquebus and musket, called for the highest skill and steadiness in the individual soldier, and cavalry too adopted the new weapon in the form of long and expensive wheel-lock pistols. In the new military system there was no place for the unprofessional soldier. The rôle of the unprofessional combatant, generally speaking, was that of an insurgent—harassing small detachments of the enemy, cutting off stragglers, and plundering convoys. Towards the end of the first civil war in England (1642-45) the country-folk banded themselves together to impose a peace on the two warring armies, but their menace was without effect, and they were easily disarmed by Fairfax and Cromwell, who did not even trouble to hold them as prisoners. The calling out of the arrêtre ban of Franche-Comté in 1675 displayed its ludicrous inefficiency, and thereafter in France, which set the fashion to Europe in all military matters, the "provincial militia," which Louvois and Barbezieux raised in place of the discredited arrêtre ban, was employed partly to find drafts for and partly to augment the regular army.

When a first line army was large enough to absorb the fighting strength of the country there was neither room nor need for a true militia force. This was the case with France under Napoleon's régime, but things were different elsewhere. In Great Britain the county militia (whose special history is briefly sketched below) was permanently embodied during the early part of the Napoleonic Wars. Destitute as it was of technical and administrative services, of higher staffs and organization, and even of cavalry, this militia was a regular army in all but name. Combining continuous service with territorial recruiting as it did, it consisted of men of a better stamp than the casually recruited regular forces. In those days, the militia was a county force commanded by the lords-lieutenant and officered by men of influence; it was not administered by the War Office.

In other countries, Napoleon's invading armies had only to deal with regular troops, which, to one observer, were crushed, nothing remained for the beaten side but to make peace with the conqueror on such terms as could be obtained. Militias existed in name as organizations, for the production of more or less unwilling drafts for the line, but the fundamental militia obligation of defending the fatherland as distinct from defending the state, produced only local and occasional outbursts of guerrilla warfare. In the Crimean War, the 1859 war in Italy, the 1866 war in Germany, and other wars (the Hungarian War of 1848-49 excepted) the forces, other than the regular troops, engaged in line were guerrilla, insurgents, Garibaldians, &c., and behind the forces in first line there were draft-supplying agencies, but no true militia. Only the British militia and the Prussian landwehr represented the self-contained army of second line, and of these the former was never put to the test, while the latter, responding feebly to a political call to arms in 1850, was in consequence so entirely reorganized that it formed a mere rear rank to the line troops. This latter system, consecrated by the German successes of 1870, became the universal model for the continent of Europe, and organized and self-contained militias to-day are only to be found in states maintaining first line armies of "general service" professionals, or in states which maintain no first line troops whatever. In the first class are the auxiliary forces of the British Empire and the United States, in the second the Swiss, Norwegian, Dutch and Swedish forces.

**MILITIA OF THE UNITED KINGDOM**

The title of "militia" disappeared from the list of the British forces in 1908, on the conversion of the existing self-contained militia into an army "special reserve," which is restricted to the rôle of providing drafts for the first line.1 The "self-contained" second line army of the present day is the Territorial Force (see UNITED KINGDOM: Army).

The county organization of England, with which throughout the militia was closely associated, began with the advent of the Saxons. The prototype of the militia was the fyrd. In this force as reorganized by Alfred liability of service was general on the part of the able-bodied adult male between the ages of 16 and 60. Although the title of "The Fyrd" survived until long after the Norman Conquest, the force established by King Alfred was known as the general levy, which was bound to appear armed when ordered to aid in suppressing domestic riots as well as in defending the realm against invasion by foreign foes. Service was restricted to the counties, except in case of invasion, when it was extended to the whole kingdom. For centuries the "hedgehog" system, in which the self-contained county militia was incorporated to serve under the principles governing the national forces of the kingdom, and form in effect with certain developments the basis of the modern militia system. The Norman Conquest was immediately followed by the introduction of the feudal levy in certain counties, and the county militia, the distinction between these forces being that while obligation to serve in the latter rested upon every male within certain limits of

---

1 Various dominions and colonies of the British Empire have militias, for which see UNITED KINGDOM: Army. For the Swiss Militia System, which is in many respects the archetype of modern militias, see SWITZERLAND; and for the organized militia of the United States see UNITED STATES.
MILITIA

age, service in the feudal levy depended upon tenure of land under the feudal law. The general levy was not in any case liable to be raised, but the feudal tenant, as a part of his feudal service, would be called upon to serve in the local forces of his lord. The feudal levy was in continental wars until they, too, successfully resisted the demand. Personal service formed the basis of both levies, but service by deputy, or payment in lieu of personal service, was allowed. This was in accordance with feudal law and the system of service by homage and the nature of theoblige. The feudal levy was discontinued during the Commonwealth and abolished at the Restoration; but liability to serve in the general levy has never been abolished. The levies in the stanniferous counties of Cornwall, Devon, and Dorset, continued to be made in the 18th century. The machinery employed to carry out the law formed the basis of the existing procedure for the enforcement of the law for the militia, which bears a strong resemblance to the means adopted from ancient times. These constitutional powers were frequently abused by "electing" or impressing men to serve out of the kingdom, but this was checked in the year 1277 by an Act of Parliament, which strictly regulated the scope and extent of military service within the kingdom, as well as the charge of the parishes or counties, but provided for service abroad at the charge of the Crown. "Commissions of musters" were a development of preceding municipal organization and mustering systems from which the commissioners registered and mustered persons liable to serve, sorted them into bands and trained and exercised them at the charge of the county. These bands became known as "train or train bands." With the reorganization of the counties, first appointed in 1539 by Edward VI., subsequently in Queen Mary's reign as lords lieutenant, and after 1603 as regulation appointed as statutory officers for the militia, their commissions at the present day being issued under the Militia Act. There do not appear to have been any clearly defined regimental organization in existence until these bands or companies were called into active service, but the Acts of the Commonwealth, 1649, supplied this defect, and initiated a permanent regimental system. One of the earliest attempts to reform the force since the time of King Alfred was made by Charles II., and when Ordnance, 1657, was issued instructing lords lieutenant to put the militia on a better footing and to fill up vacancies among the officers. Cromwell subsequently issued similar orders couched in strong terms, though unenacted, with the duties of the officers clearly defined, and being recognized, the militia being raised by commissions. The great services rendered by the militia in the "crown" or "crown" of Worcester are a historic exception to the general decadence of second line troops in the 17th and 18th centuries (see Great Rebellion). At the Restoration an act was passed declaring that the control of the militia was the prerogative of the king. By the same statute the"crown" authority was placed under the chiefs of the militia, vested with the appointment of officers, but with a reservation to the Crown in the way of commissioning and dismissal. The cost of the annual training—for fourteen days—fell upon the local authority. Official control of the force was thus beginning to be assumed by the Crown, but with a power to the officers of fining and of imprisoning in default. Upon this footing the militia of England remained for nearly a century. In 1715 a general application for the appointment of county commissioners was recognized as an instrument for defence and for the preservation of internal order, while it was especially popular from the circumstance that from its constitution and organization the Crown could not use it as a means of violating the constitution or abridging the liberty of the subject. It was controlled and regulated in the county; it was offered by the landowners and their relatives, its ranks were filled by men not depending for their subsistence or advancement upon the favour of the Crown; its numbers and maintenance were beyond the royal control; its government was by statute. While the supreme command was distinctly vested in the Crown, every provision was thus taken and every use made for the main purpose of that purpose, which was if not being summoned for the purpose). During the embodiment or annual training it was subject to the Mutiny Act, except that no punishment during training was to extend to the calling out of the militia. After 1740, when Ordnance, 1754; Men volunteering to serve recognized as counting towards the quota.

1761. Raising of quota made compulsory on counties under penalty of fines.

Mutiny Act applied to militia when out for training as well as when embodied.

1775. (American War.) Act passed empowering embodiment of militia in case of colonial as well as domestic rebellion.

1786. Charge on parishes for storage of arms, &c., transferred to counties.

1795. Embodiments into regulars encouraged.

1796. Supplementary militia formed, consisting of 63,878 men.

1798. (Irish Rebellion.) English militia voluntarily for service in Ireland.

1799. Irish militia voluntarily for service in Great Britain.

1802. 45,492 men raised for militia by ballot, but of these 40,998 were substitutes.

1805. Militia is liable for life to purposes of recruiting for regulars.

1853. 20,000 men were attempted to be formed, but this was not successful.
MILK

1806. Training Act to raise by ballot 200,000 men to be trained for one whole year, and then to discharge them from training for two years.

1808. MILITIA ACT. The militia was raised under above Act, local militia (which is in effect the old general levy) established in addition to general militia then embodied.

27,000 militiamen volunteered to regular army during pre-1812 period.

1811. English militia, hitherto not liable to serve out of the kingdom, now made liable to serve in any part of the United Kingdom, so certain restrictions, which were subsequently (in 1859) removed.

Method of obtaining men from militia for regulars further systematized.

1812. In the year 1812 there were 250 regiments of local militia, with an establishment of 240,388 men and 214,418 actually enrolled.

1813. During ten years, from 1803 to 1813, nearly 100,000 militiamen joined the regular army.

Act passed to enable militia to serve abroad as militia with their own officers. Three strong battalions joined the British army in France.

1815. Militiamen recruited in great numbers the army which fought at Waterloo.

Local militia ceased to be raised.

1816. Local and Militia Acts suspended.

General militia disbanded.

1820-21-25. Militia called out for training.

1825. Act passed suspending ballot for the general militia.

1831. Military forces of the world, including the United Kingdom, of which 2,000,000 men were called upon in emergencies, in the following proportions to the establishments of the various corps: Artillery, one-third; engineers, one-fourth; infantry, one-fourth; and the rest. The militia was first formed in 1867, and in 1900 numbered 30,000 men.

1832. During an emergency in 1878, 20,000 militia regiments joined the regular army. The term "militia" reserve was therefore a complete misnomer. The special service militia reserve was created as above, for special service if not less than 75% of the officers and men present at the time of declaration of a voluntary offer to engage for special service in any part of the world, and if in the infancy at least 500 and in the artillery at least 250 men were accepted as qualified. Individual militia regiments were not to serve except with their militia unit if it was registered for service, or else for special service with the regular forces. Liability for service was limited to twelve months. The special service of the militia was to continue in peace and war.

1877. The special service of the militia was continued in peace and war.

1881. The special service of the militia was continued in peace and war.

1885. The special service of the militia was continued in peace and war.

1891. The special service of the militia was continued in peace and war.

1895. The special service of the militia was continued in peace and war.

1899. The special service of the militia was continued in peace and war.

1901. The special service of the militia was continued in peace and war.

1905. The special service of the militia was continued in peace and war.

1909. The special service of the militia was continued in peace and war.

1911. The special service of the militia was continued in peace and war.

1913. The special service of the militia was continued in peace and war.

1915. The special service of the militia was continued in peace and war.

1917. The special service of the militia was continued in peace and war.

1919. The special service of the militia was continued in peace and war.

1921. The special service of the militia was continued in peace and war.

1925. The special service of the militia was continued in peace and war.

1929. The special service of the militia was continued in peace and war.

1931. The special service of the militia was continued in peace and war.

1933. The special service of the militia was continued in peace and war.

1935. The special service of the militia was continued in peace and war.

1937. The special service of the militia was continued in peace and war.

The milk of various domesticated animals is more or less used by man for food. The milk of the cow, which may be taken as typical of all others, and is indeed by far the most important and valuable of all (see DAIRY and DAIRY FARMING), is, when newly drawn, an opaque white fluid, with a yellowish tinge, soft, bland and sweetish to the taste, and possessed of a faintly animal odour. This odour, according to Schreiner, is due to the presence of sulphuric hydrogen, and disappears after a short exposure. The specific gravity of milk ordinarily ranges from 1.029 to 1.053; very seldom reaching 1.035 or falling as low as 1.027. In chemical composition it consists of an emulsion...
of fatty globules (cream) in a watery alkaline solution of cascin, and a variety of sugar, peculiar to milk, called lactose. The fat (which when separated we know as butter) and the lactose constitute the carbonaceous portion of the milk regarded as food. The cascin, which forms the principal constituent of cheese, and a certain amount of albumen which is present, form the nitrogenous, while the complex saline substances and water are the mineral constituents. These various substances are present in the proportions which render milk a perfect and typical food suitable to the wants of the young of various animals for which it is provided by nature. The milk of animals, so far as is known, contains them, although they are present in somewhat different proportions. It is probable that the milk of ruminants possesses certain chemical and physiological distinctions from that of other, non-ruminant animals, which will account for the virtues attributed to the milk of the ass and mare.

The following table exhibits the chemical constitution of the kinds of milk most frequently used by man:

<table>
<thead>
<tr>
<th>Kind of Milk</th>
<th>Cow</th>
<th>Goat</th>
<th>Ewe</th>
<th>Mare</th>
<th>Ass</th>
<th>Human</th>

In addition to these constituents milk contains small proportions of the gases carbonic acid, sulphurated hydrogen, nitrogen and oxygen, and minute quantities of other principles, the constant presence and essential conditions of which have not been determined. These consist of gelatin and lactochrome, substances peculiar to milk, discovered by Winter Blathy, with certain animal principles such as lecin, pepton, kreatin, tyrosin, &c. The salts in milk consist, according to the average of numerous analyses by Fleischmann, of the following constituents:

- Phosphoric acid: 28-31
- Chlorine: 16-34
- Lime: 27-00
- Soda: 10-00
- Potash: 17-34
- Magnesia: 4-07
- Ferric oxide: 0-62

Milk is not thus to be regarded as a definite chemical compound nor even as a mixture of bodies fixed and invariable proportion. Not only does the milk variable in different races and breeds of cows vary within comparatively wide limits, but the same animal is subject to extensive fluctuation. The principal causes of variation in the individual are age, period of lactation, nature and amount of food, state of health, and treatment, such as frequency of milking, &c. The following table indicates the range of normal variations:

<table>

The average quantity of milk yielded by cows is also highly variable, both in individuals and breeds.

Milk and Disease.—Although the milk of a perfectly healthy cow may be absolutely sterile, it is difficult to obtain it in that condition. In the report of the joint committee appointed for the purpose by the county boroughs of Bradford, Hull, Leeds, Rotherham and Sheffield in 1908, the following conclusions were drawn: (1) Cows' milk freshly drawn from the udder by ordinary methods contains bacteria. They are more numerous in the first flow of the milk. (2) There is a great increase in contamination in the milk of each subsequent flow before it reaches the customer. This is due to (a) the dirty condition of the cows' udders, (b) the imperfect cleansing of the cans and the hands of the milkers. The committee recommend:

1 Ewe's milk is exceedingly variable, especially in its percentage of fat. The above analysis is one of nine by Dr Arthur Vockeler, in which the fat was found to range from about 2 to 12.5.

MILKWORT, in botany, the common name for plants of the genus Polygala (natural order Polygalaceae), a large genus widely dispersed in temperate and tropical regions and represented by a few species in Britain. The common species, P. vulgaris, is an admirable plant for permanent hay meadows throughout the British Isles. The stems are 2 to 10 in. long and bear narrow rather tough leaves and small, ½ to ¾ in. long, white, pink, blue, lilac or purple flowers. The flowers (see fig.) are peculiar in form and arrangement of parts; they have five free sepals the two inner of which (b) are large petaloid and winglike, forming the most conspicuous part of the flower; the petals are united below with the sheath of the eight stamens forming a tube split at the base behind; their form recalls that of the pea family. The name Polygala is from the Greek πολύς, much,
and yāla, milk, the plant being supposed to increase the yield of milk in cows. Some species with showy flowers are known in cultivation as greenhouse, or hardy annual or perennial, herbs, or shrubs. The root of P. senega, snake-root, a North American species is official. Sea milkwort is the common name for Glaux maritima, a small succulent herb found on seashores and in estuaries in the British Isles; it belongs to the primrose order (Primulaceae).

After Berg & Schmidt, from Strasburger’s Lehrbuch der Botanik, by permission of Gustav Fischer.

Polygala senega.

A. Flower; a, small sepal; b, large sepal; c, keel, representing the anterior petal; d, its fimbriated edge; e, lateral petals.

B. The 8 stamens united into a sheath below; f, anthers (magnified).

MILL, JAMES (1773–1836), historian and philosopher, was born on the 6th of April 1773, at Northwater Bridge, in the parish of Lombe-Fert, Forfarshire, the son of James Mill, a shoemaker. His mother, Isabel Fenton, of a good family which had suffered from connexion with the Stuart rising of 1745, resolved that he should receive a first-rate education, and sent him first to the parish school and then to the Montrose Academy, where he remained till the usual age of seventeen and a half. He then entered the University of Edinburgh, where he distinguished himself as a Greek scholar. In October 1798 he was licensed as a preacher, but met with little success. From 1790 to 1802, in addition to holding various tutorships, he occupied himself with historical and philosophical studies. Finding little prospect of a career in Scotland, in 1802 he went to London in company with Sir John Stuart, then member of parliament for Kincardineshire, and devoted himself to literary work. From 1803 to 1806 he was editor of an ambitious periodical called the Literary Journal, which professcd to give a summary view of all the leading departments of human knowledge. During this time he also edited the St James’s Chronicle, belonging to the same proprietor. In 1804 he wrote a pamphlet on the corn trade, arguing against a bounty on the exportation of grain. In 1805 he published a translation (with notes and quotations) of C. F. Villiers’s work on the Reformation, an unsparing exposure of the alleged vices of the papal system. In 1805 he married Harriet Burrow, whose mother, a widow, kept an establishment for lunatics in Hoxton. He then took a house in Pentonville, where his eldest son, John Stuart Mill (q.v.), was born in 1806. About the end of this year he began his History of India, which he took twelve years to complete, instead of three or four, as he had expected.

In 1808 he became acquainted with Jeremy Bentham, and was for many years his chief companion and ally. He adopted Bentham’s principles in their entirety, and determined to devote all his energies to bringing them before the world. Between 1806 and 1818 he wrote for the Anti-Jacobin Review, the British Review and the Electric Review; but there is no means of tracing his contributions. In 1808 he began to write for the Edinburgh Review, to which he contributed steadily till 1813, his first known article being “Money and Exchange.” He also wrote on Spanish America, China, General Miranda, the East India Company, and the Liberty of the Press. In the Annual Review for 1808 two articles of his are traced—a “Review of Fox’s History,” and an article on “Bentham’s Law Reforms,” probably his first published notice of Bentham. In 1811 he co-operated with William Allen (1770–1843), quaker and chemist, in a periodical called the Philanthropest. He contributed largely to every number—his principal topics being Education, Freedom of the Press, and Prison Discipline (under which he expounded Bentham’s "Panopticon"). He made powerful onslaughts on the Church in connexion with the Bell and Lancaster controversy, and took a prominent part in the discussions which led to the foundation of London University in 1825. In 1814 he wrote a number of articles, containing an exposition of utilitarianism, for the supplement to the fifth edition of the Encyclopaedia Britannica, the most important being those on “Jurisprudence,” “Prisons” and “Government.”

In 1818 the History of India was published, and obtained a great and immediate success. It brought about a change in the author’s position. The year following he was appointed an official in the India House, in the important department of the examiner of Indian correspondence. He gradually rose in rank till he was appointed, in 1820, head of the office, with a salary of £1000, raised in 1836 to £2000. His great work, the Elements of Political Economy, appeared in 1821 (3rd and revised ed. 1826).

From 1824 to 1826 Mill contributed to the Westminster Review, started as the organ of his party, a number of articles in which he attacked the Edinburgh and Quarterly Reviews and ecclesiastical establishments. In 1829 appeared the Analysis of the History of India, From 1818 to 1825 Mill was largely occupied in the defence of the East India Company, during the controversy attending the renewal of its charter, he being in virtue of his office the spokesman of the court of directors. For the London Review, founded by Sir William Motesworth in 1834, he wrote a notable article entitled “The Church and its Reform,” which was much too sceptical for the time, and injured the Review. His last published book was the Fragment on Mackintosh (1835). He died on the 23rd of June 1836.

Mill had a thorough acquaintance with Greek and Latin literature, general history, political, mental and moral philosophy. His intellect was logical in the highest degree; he was clear and precise, an enemy of loose reasoning, and quick to refute prevailing fallacies. All his work is marked by original constructive thought, except in a few subjects, in which he confessedly expounded Bentham’s views. At a time when social subjects were as a rule treated empirically, he brought first principles to bear at every point. His greatest literary monument is the History of India. The materials for narrating the acquisition by England of its Indian Empire were put into shape for the first time; a vast body of political theory was brought to bear on the delineation of the Hindu civilization; and the conduct of the actors in the successive stages of the conquest and administration of India was subjected to a severe criticism. The work itself, and the author’s official connexion with India for the last seventeen years of his life, effected a complete change in the whole system of governing that country.

Mill played a great part also in English politics, and was, more than any other man, the founder of what was called “philosophic radicalism.” His writings on government and his personal influence among the Liberal politicians of his time determined the change of view from the French Revolution theories of the rights of man and the absolute equality of men to the claiming of securities for good government through a wide extension of the franchise. Under this banner it was that the Reform Bill was fought and won. His Elements of Political Economy, which was intended only as a textbook of the subject, shows all the author’s precision and lucidity. As Dr J. K. Ingram said, it has the “character of a work of art.” It followed up the views of Ricardo, with whom Mill was always on terms of intimate friendship, but it was brought to bear on the whole body of political theory, and in the process of doing so was free from some of the vices of Ricardo’s own method.

Among the more important of its theses are: (1) that the chief problem of practical reformers is to limit the increase of population, on the assumption that capital does not naturally increase at the same rate as population (ii. § 2, art. 3); (2) that the value of a thing depends entirely on the quantity of labour put into it; and (3) that what is now known as the “uneared increment” of land is a proper object for taxation. The work as a whole is a striking example of the weakness of treating
economic problems from a purely a priori standpoint by the deductive method.

By his Analysis of the Mind and his Fragment on Mackintosh Mill acquired a position in the history of psychology and ethics.

He took up the problems of mind very much after the fashion of the Scottish school, as then represented by Reid, Stewart and Brown, but made a new start, due in part to Hartley, and still more to his own independent thinking. He carried out the principle of association into the analysis of the complex emotional states, as the affections, the aesthetic emotions and the moral sentiment, all which he endeavoured to resolve into pleasurable and painful sensations. But the salient merit of the Analysis is the constant endeavour after precise definition of terms and clear statement of doctrines. The Fragment on Mackintosh is a severe exposure of the flimsiness and misrepresentations of Sir James Mackintosh's famous Dissertation on the Progress of Ethical Philosophy (1830), and discusses the foundations of ethics from the autobiographical point of view.

ii. (1900), and article in Dict. Nat. Biog.; A. Bain, James Mill (1882); G. S. Bower, Hartley and James Mill (1881); James McCosh, Scottish Philosophy (1885); J. Mill, Autobiography, reprint 1870; Eng. trans., 1873; J. Morley in Fortnightly Review, xxvii. (1882); Graham Wallas, The Life of Francis Place (1898).

MILL, JOHN (c. 1806–1707), English theologian, was born about 1845 at Shap in Westmorland, entered Queen's College, Oxford, as a servertor in 1861, and took his master's degree in 1863. He was made a fellow of his college in 1864, and took the Oxford d.D. in 1867. He was a prebendary of the Sheldonian Theatre. Soon afterwards he was chosen fellow and tutor of his college; in 1766 he became chaplain to the bishop of Oxford, and in 1768 he obtained the rectory of Bletchington, Oxfordshire, and was made chaplain to Charles II.

From 1683 till his death he was principal of St. Edmund's Hall; and in 1764 he was nominated by Queen Anne to a prebendal stall in Canterbury. He died on the 23rd of June 1707, just a fortnight after the publication of his Greek Testament.

Mill's Novum Testamentum græcum, cum lectionibus variis vitius MSS. exemplarium, versionum, editionum SS. patrum et scribtorum ecclesiasticorum, et in codex notis (Oxford, fol. 1707), was undertaken by the advice and encouragement of John Fell (q.v.), and it preoccupied the field of New Testament criticism; it represents the labour of thirty years, and is admitted to mark a great advance on all that had previously been achieved. The text is indeed that of R. Stephanus (1550), but the notes, besides embodying all previous criticism, are full of various readings, add a vast number derived from his own examination of many new MSS. and Oriental versions (the latter unfortunately he used only in the Latin translation). Though a wealth of information given by Mill is still compared with that in modern editions, it is probable that no one person, except perhaps Tischendorf, has added so much material for the work of textual criticism. He was the first to notice, though only incidentally, the valuable nature of the Codex Alexandrinus, the only representative of an ancient non-Western Greek text then sufficiently known; this hint was not lost on Bentley (see Westcott and Hort, Introduction to New Testament).

Mill's various readings, numbering about thirty thousand, were attacked by Daniel Whitby (1638–1726) in his Examen as destroying the validity of the text; Antony Collins also argued in the same sense though with a different object. The latter called forth a reply from Bentley (Philetemuthius Ipsiensis). In 1716 Kuster reprinted Mill's Testament at Amsterdam with the readings of twelve additional MSS.

MILL, JOHN STUART (1806–1873), English philosopher and economist, son of James Mill, was born on the 20th of May 1806 in his father's house in Pentonville, London. He was educated exclusively by his father, who was a strict disciplinarian, and at the age of three was taught the Greek alphabet and long lists of Greek words with their English equivalents. By his eighth year he had read Aesop's Fables, Xenophon's Anabasis, and the whole of Herodotus, and was acquainted with Lucian, Diogenes Laërtius, Isocrates and six dialogues of Plato (see his Autobiography). He had also read a great deal of history in English—Robertson's histories, Hume, Gibbon, Robert Watson's Philip II. and Alexandre His Life and Roman History, part of a translation of Rollin's Ancien History, Longhorne's Plutarch, Burnet's History of My Own Times, thirty volumes of the Annual Register, Millar's Historical View of the English Government, Moschin's Ecclesiastical History, M'Crie's Knox, and two histories of the Quakers. A contemporary record of Mill's studies from eight to thirteen is published in Bain's sketch of his life. It shows that the Autobiography rather understates the amount of work done. At the age of eight he began Latin, Euclid, and algebra, and was appointed schoolmaster to the younger children of the family. His main reading was still history, but he went through the Latin and Greek authors commonly read in the schools and universities, besides several that are not commonly read by undergraduates. He was not taught to compose either in Latin or in Greek, and he was never an exact scholar; it was for the subject matter that he was required to read, and by the age of ten he could read Plato and Democritus with ease. His father's History of India was published in 1818; immediately thereafter, about the age of twelve, John began a thorough study of the scholastic logic, at the same time reading Aristotle's logical treatises in the original. In the following year he was introduced to political economy and studied Adam Smith and Ricardo with his father.

Not unnaturally the training which the younger Mill received has aroused amazement and criticism; and it is reasonable to doubt whether the material knowledge which he retained in the result was as valuable to him as his father imagined. It is important, however, to note that the really important part of the training was the close association which it involved with the strenuous character and vigorous intellect of his father. From his earliest years he spent much time in his father's study and habitually accompanied him to his private lectures. Much therefore of what he acquired was assimilated without difficulty, and the accuracy of his impressions was tested by his subsequently drafting a résumé of their conversations. He thus learned early to grapple with difficulties and to accustom himself to the necessity of precision in argument and expression. It was an inevitable result of such an education that Mill acquired many of his father's speculative opinions, and his father's way of defending them. But he did not receive the impress passively and mechanically. "One of the grand objects of education," according to the elder Mill, "should be to generate a constant and political concern about evidence." The duty of collecting and weighing evidence for himself was at every turn impressed upon the boy; he was taught to accept no opinion on authority.

He was deliberately educated as an apostle, but it was as an apostle of reason and human affairs, not as an apostle of any system of dogmatic tenets. It was to prevent any falling off from this high moral standard till it should become part of his being that his father kept the boy so closely with himself. Mill expressly says that his childhood was not unhappy. It seems unhappy only when we compare it with the normal life of a boy and decline to imagine its peculiar enjoyments and satisfactions. Mill complains that his father often required more than could be expected of him, but his tasks were not so severe as to prevent him from growing up a healthy and high-spirited boy, though he was not constitutionally robust, and his pursuits were so different from those of other boys of the same age.

From May 1820 till July 1821 Mill was in France in the family of Sir Samuel Bentham, brother of Jeremy Bentham. Away from his father he maintained his laborious habits. Copious extracts from a diary kept by him at this time are given by Bain; they show how methodically he read and wrote, studied chemistry and botany, tackled advanced mathematical problems, made notes on the scenery and the people and customs of the country. He also gained a thorough acquaintance with the French language. On his return in 1821 he added to his work the study of psychology, and that of Roman law, which he read with John Austin, his father having half decided on the bar as the best profession open to him. In 1822, however, when he had just completed his seventeenth year, this intention was abandoned, and he entered as a clerk in the examiner's office of the India House, with the understanding that he should be employed from the beginning in preparing drafts of despatches and he thus trained up as a successor to those who then filled the highest departments of the office."
Mill's work at the India House, which was henceforth his livelihood, did not come before the public; hence some have scolded his political writings as the work of an abstract philosopher, entirely unacquainted with affairs. From the house he was more than a clerk, and after a short apprenticeship he was promoted, in 1828, to the responsible position of assistant-examiner with a salary of £600 a year. The duty of the so-called examiners was to examine the letters of the agents of the Company in India, and to draft instructions in reply. The character of the Company's government was almost entirely dependent upon their abilities as statesmen. For twenty years, from 1836 (when his father died) to 1856, Mill had charge of the Company's relations with the native states, and in 1856 he became chief of the office with a salary of £1,000. In the hundreds of despatches that he wrote in this capacity, much, no doubt, was done in accordance with established routine, but few statesmen of his generation had a wider experience of the responsible application of the principles of government. About this work he said little in the Autobiography, probably because his main concern there was to expound the influences that effected his moral and mental development.

About the time of his entering the India House Mill read Ducan's exposition of Bentham's doctrines in the Treaté de législation, which made a lasting impression upon him. When he laid down the last volume, he was attracted not by the subjects of his chosen country at being. It gave unity to the detached and fragmentary parts of his knowledge and beliefs. The impression was confirmed by the study of the English psychologists, as well as Condillac and Helvetius, and in 1822-1823 he established among a few friends of the "Utilitarian" Society, taking the word as he tells us, from Galt's Annuals of the Parish. Two newspapers were open to him—the Traveller, edited by a friend of Bentham's, and the Morning Chronicle, edited by his father's friend Black. One of his first efforts was a solid argument for freedom of discussion, in a series of letters to the editors of newspapers in a sketch of the polemic work of Richard Carlile. But he watched all public incidents with a vigilant eye, and seized every passing opportunity of exposing departures from sound principle in parliament and courts of justice. Another outlet was opened up for him (April 1824) by the starting of the Westminster Review, and still another in the following year in the Parliamentary History and Review. This year also he found a congenial occupation in editing Bentham's Rationale of Judicial Evidence. All the time, his mind full of public questions, he discussed eagerly with the many men of distinction who came to his father's house in entering into the most intimate discussion of a society formed at Grote's house in 1825, and in set debates at a Speculative Society formed in the same year.

From the Autobiography we learn that in 1826 Mill's enthusiasm was checked by a mingling as to the value of the ends which he had set before him. This expression was the result, no doubt, of his strenuous training and the comparative lack of congenial friendships. His father was reserved, undemonstrative even to the pitch of chilling sternness, and among young Mill's comrades contempt of feeling was almost a watchword. Himself absorbed in abstract questions and projects of general principle, he was careless of personal attachment. On the other hand without experience he could not have been prepared for the actual slowness of the reformer's work. In 1826 he looked back to four years of eager toil. What were the results? He had become convinced that his comrades in the Utilitarian Society, never more than ten, had not the stuff in them for a world-shaking propaganda; the society itself was dissolved; the Parliamentary Review was a failure; the Westminster did not pay its expenses; Bentham's Judicial Evidence produced little effect on the reviewers. His own reception in the Speculative Debating Society, where he first measured his strength in public contest, was calculated to produce self-distrust. He found himself looked upon with curiosity as a precocious phenomenon, a "made man," an intellectual machine set to grind certain tines. The outcome of the period of depression was a broadening of his outlook on the problems which he had set himself to solve. He now saw that regard for the public good was too vague an object for the satisfaction of a man's affections. It is a proof of the dominating force of his character that it cost the younger Mill such an effort to shake off his stern creed about poetry and probable immortality. Like Plato, the elder Mill would have put points under ban as enemies of truth, and he subordinated private to public affections. Landor's maxims of "few acquaintances, fewer friends, no familiarities" had his cordial approval. These doctrines the younger Mill now felt himself forced in reason to abandon. Too much in awe of his father to make him a confidant, he wrestled in the gloomy solitude of his own mind. He gained from the struggle a more catholic view of human happiness, at dessert, for he poetry of nature and the affections as well as the poetry of heroic unschism, a disposition to study more sympathetically the point of view of opponents, a more courteous style of polemic, a hatred of sectarianism, an ambition, no less noble and disinterested, and moderated to practical possibilities.

In the course of the next few years he wrote comparatively little, but he continued his reading, and also derived much benefit from discussions held twice a week at Grote's house in Threadneedle Street. Gradually also he had the satisfaction of seeing the debates in the Speculative Society becoming famous in the world. A crowd of other social and political questions was made. He ceased to attend the society in 1829, but he carried away from it the strengthening memory of failure overcome by persevering effort, and the important doctrinal conviction that a true system of political philosophy was "something much more complex and many-sided than he had previously had any idea of, and that its office was to supply, not a set of model institutions but principles from which the institutions suitable to any given circumstances might be deduced."

The political philosophy of Mill appeared in a series of contributions to the Examiner in the autumn of 1830 entitled "Prospects in France." He was in Paris soon after the July Revolution, and made the acquaintance of the leading spirits among the younger men; in his discussion of their proposals we find the germs of many thoughts afterwards more fully developed in his Representative Government. It is from this time that Mill's letters supply a connected account of his life (see Hugh Elliott, Letters of John Stuart Mill, 1910).

The letters in the Examiner may be taken as marking the close line of his approach to the mediative search, and his return to hopeful activity. It was characteristic of his nature that he should be stirred to such delight by the Revolution in France, and should labour so earnestly to make his countrymen understand with what gravity and sobriety it had been effected. Their own Reform Bill came soon after and it is again characteristic of Mill—at once of his enthusiasm and of his steady determination to do work that nobody else seemed able or willing to do—that we find him in the heat of the struggle in 1831 writing to the Examiner a series of letters on "The Spirit of the Age," which drew from Carlyle the singular exclamation, "Here is a new master!" How little this criticism was justified may be seen from the fact that Mill's inductive logic was the direct result of his aspirations after political stability as determined by the dominion of the wisest (Examiner letters). "Why is it," he asked, "that the multitude accept implicitly the decisions of the wisest, of the specially skilled, in physical science?" Because in physical science there is all but complete agreement in opinion. "And why this agreement?" Because all accept the same methods of investigation, the same tests of truth. Is it possible then to obtain unanimity as to the methods of arriving at conclusions in social and political matters, so as to secure similar agreement of opinion among the specially skilled, and similar general respect for their authority? The same thought appears in a review of Herschel's Natural Philosophy, written about the same time. Mill remarks that the uncertainty hanging over the very elements of moral and social philosophy proves that the means of arriving at the truth in those sciences are not yet
MILL, JOHN STUART

properly understood. "And whither," he adds, "can mankind so advantageously turn, in order to learn the proper means, and to form their minds to the proper habits, as to that branch of knowledge in which by universal acknowledgment the greatest number of truths have been ascertained, and the greatest possible degree of certainty arrived at?"

By 1831 the period of depression had passed; Mill's enthusiasm for humanity had been thoroughly reawakened, and had taken the definite shape of an aspiration to supply an unimpeachable method of search for conclusions in moral and social science. No mystic ever worked with warmer zeal than Mill. But his zeal encountered a check which baffled him for several years, and which left its mark in various inconsistencies and incoherences in his completed system. He had been bred by his father in a great veneration for the syllogistic logic as an antidote against confused thinking. He attributed to his early discipline in this logic an impatience of vague language which in all likelihood was really fostered in him by his study of the Platonic dialogues and of Bentham, for he always had in himself more of Plato's fertile ingenuity in canvassing the meaning of vague terms than the schoolman's rigid consistency in the use of them. Be this as it may, enthusiastic as he was for a new logic that might give certainty to moral and social conclusions, Mill was no less resolute that the new logic should stand in no antagonism to the old. In his Westminster review of Whately's Logic in 1828 (invaluable to all students of the genius of Mill's logic) he appears, curiously enough, as an ardent and loud champion of the syllogistic logic against highfliers such as the Scottish philosophers who talk of "superseding" it by "a supposed system of inductive logic." His inductive logic must "supplement and not supersede." But for several years he searched in vain for the means of concatenation.

Meantime, while recurring again and again, as was his custom, to this cardinal difficulty, Mill worked indefatigably in other directions where he saw his way clear. The working of the new order in France, and the personalities of the leading men, had a profound interest for him; he wrote on the subject in the Examiner. He had ceased to write for the Westminster in 1828; but during the years 1832 and 1833 he contributed many essays to Tait's Magazine, the Jurist, and the Monthly Repository. In 1833 Sir William Molesworth founded the London Review with Mill as editor; it was amalgamated with the Westminster (as the London and Westminster Review) in 1836, and Mill continued editor (latterly proprietor also) till 1840. Much of what he wrote then was subsequently incorporated in his systematic works. Two of his essays were reprinted in his two volumes of Dissertations and Disquisitions (1859). The essays on Bentham and Coleridge constituted the first manifesto of the new spirit which Mill sought to breathe into English Radicals. But the reprinted papers give no just idea of the immense range of Mill's energy at this time. His position in the India Office, where alone he did work enough for most men, cut him off from entering parliament; but he laboured hard though ineffectually to influence the legislature from without by combating the disposition to rest and be thankful. In his Autobiography he admits that he attempted to form a Radical party in parliament at that time was chimerical.

It was in 1837, on reading Whewell's Inductive Sciences and re-reading Herschel, that Mill at last saw his way clear both to formulating the methods of scientific investigation and joining on the new logic as a supplement to the old. The Logic was published in 1843. In 1844 appeared his Essays on Some Unsettled Questions in Political Economy. These essays were worked out and written many years before, and show Mill in his earlier stage as a political economist. Four out of the five essays represent fuller and more powerful solutions of perplexing technical problems—the distribution of the gains of international commerce, the influence of consumption on production, the definition of productive and unproductive labour, the precise relations between profits and wages. Though Mill appears here purely as the disciple of Ricardo, striving after more precise statement, and reaching forward to further consequences, we can well understand in reading these essays how about the time when he first sketched them he began to be conscious of power as an original and independent thinker.

That originality and independence became more conspicuous when he reached the second stage of his career, as a political economist. It was in the first stage he was called a political economist, for the intellectual side of the state of things which he was studying. Mill's work, and Mill's success, was the work of a man who had been trained in all his years in the principles of political economy as taught by Ricardo, and with no previous training in any other science or literature. He was a man of minute and tireless observation, and of unerring judgment, and of a rare talent for abstract thought. He could see behind events, as they passed, where others could only see the event, and know that it was an event. He could see the drift of events as they passed, and knew that it was the drift, and not the events which mattered. This was the drift of events which he was studying, and to which he was bringing the method of the political economist. It was this drift of events which he was studying, and to which he was bringing the method of the political economist. It was this drift of events which he was studying, and to which he was bringing the method of the political economist. It was this drift of events which he was studying, and to which he was bringing the method of the political economist. It was this drift of events which he was studying, and to which he was bringing the method of the political economist.

During the seven years of his married life Mill published less than in any other period of his career, but four of his most

1 Mrs Taylor (Harriet Hardy) was the married life Mill published less than in any other period of his career, but four of his most
closely reasoned and characteristic works, the Liberty, the Utilitarianism, the Thoughts on Parliamentary Reform, and the Subjection of Women, besides his posthumously published essays on Nature and on the Utility of Religion, were thought out and partly written in collaboration with his wife. In 1856 he became head of the examiner's office in the India House, and for two years, till the dissolution of the Company in 1858, his official work, never a light task, kept him fully occupied. It fell to him as head of the office to write the defence of the Company's government of India when the transfer of its powers was proposed. He has left us a valuable and compressed treatise in which he substantiated the proud boast for the Company that "few governments, even under far more favourable circumstances, have attempted so much for the good of their subjects or carried so many of their attempts to a beneficial issue," and exposed the defects of the proposed new government, are models of trenchant and dignified pleading.

On the dissolution of the Company Mill was offered a seat in the new council, but declined, and retired with a pension of £1500. His retirement from official work was followed almost immediately by his wife's death at Avignon, whether they lived consciously or unconsciously, a receiving of the family. So that for the rest of his life he spent most of his time at a villa at St Véran, near Avignon, returning to his Blackheath residence only for a short period in each year. He sought relief in active literary occupation, in politics, sociology and psychology. He published, with a touching dedication to his wife, the treatise on Liberty, which they had wrought out together. He then turned to politics, and published, in view of the impending Reform Bill, a pamphlet on parliamentary reform. The chief feature in this was an idea concerning which he and Mrs Mill often deliberated—the necessity of providing checks against uneducation democracy. His suggestion of a plurality of votes, proportioned to the electorate's degree of education, was avowedly put forward only as an ideal; he admitted that no authentic test of education could for the present be found. An anonymous Conservative caught at the scheme in another pamphlet, proposing income as a test. Soon after Mill supported in Fraser's, still with the same object, Hare's scheme for the representation of minorities. In the autumn of the same year he turned to psychology, reviewing Bain's works in the Edinburgh Review. In his Representative Government (1860) he systematized opinions already put forward in his journal and his utilitarianism (published in Fraser's in 1861) was a closely-reasoned systematic attempt to answer objections to his ethical theory and remove misconceptions of it. He was especially anxious to make it clear that he included in "utility" the pleasures of the imagination and the gratification of the higher emotions, and to show how powerfully the good of mankind as a motive appealed to the imagination. His next treatise, The Subjection of Women, was not published till 1869. His Examination of Hamilton's Philosophy, published in 1869, had engaged a large share of his time for three years before.

While mainly occupied in those years with philosophical studies, Mill did not remit his interest in current politics. He supported the North in the American crisis of 1862, using all his strength to explain what has since been universally recognized as the issue really at stake in the struggle, the abolition of slavery. It was characteristic of the closeness with which he watched current events, and of his zeal in the cause of "lucidity," that when the Reader, an organ of science and unpartisan opinion, fell into difficulties in 1865 Mill joined with some distinguished men of science and letters in an effort to keep it afloat. He supplied part of the money for carrying it on, contributed several articles, and assisted the editor, Fraser Rae, with his advice. The effort was vain, though such men as Herbert Spencer, Huxley, Tyndall, Cairnes, Mark Pattison, F. Harrison, Sir Frederick Pollock and Lockyer were among the contributors.

In 1865 he agreed to stand as parliamentary candidate for Westminster, on conditions strictly in accordance with his principles. He would not canvass, nor pay agents to canvass for him, nor would he engage to attend to the local business of the constituency. He was with difficulty persuaded even to address a meeting of the electors. The story of this remarkable election has been told by James Beal, one of the most active supporters of Mill's candidature. In parliament he adhered to the strong principle of doing only work that needed to be done, and that nobody else could perform better. He may have been a consciousness of this fact which prompted a remark, made by the Speaker, that Mill's presence in parliament elevated the tone of debate. The impression made by him in parliament is in some danger of being forgotten, because he was not instrumental in carrying any great measure that might serve as an abiding memorial. But, although his first speech on the bill for the prevention of cattle diseases excited the opposition of country members, and a subsequent speech against the suspicious of the habeas Corpus Act in Ireland was very favourably received in the House of Commons, his speeches were in the ear of the House. The only speech made by him during his three years in parliament that was listened to with impatience, was curiously enough, his speech in favour of countering democracy by providing for the representation of minorities. His attack on the conduct of Governor Eyre in Jamaica (1869) was listened to, but with repugnance by the majority, although his action in this matter in and out of parliament was far from being ineffectual. He took an active part in the debates on Dizraeli's Reform Bill (moving an amendment to omit the word "man" and insert "person"), and helped to extract from the government several useful modifications of the Bill for the Prevention of Corrupt Practices. The reform of land tenure in Ireland, the representation of women, the reduction of the national debt, the reform of London government, the abrogation of the Declaration of Paris, were among the topics on which he spoke with marked effect. He took occasion more than once to enforce what he had often advocated in writing, England's duty to intervene in foreign politics in support of the cause of freedom. As a speaker Mill was somewhat hesitating, pausing occasionally as if to recover the thread of his argument, but he showed great readiness in extemporaneous arguments. As a candidate for ministerial office, he might be regarded as a failure in parliament, but there can be no doubt that his career there greatly extended his influence.

Mill's subscription to the election expenses of Bradlaugh, and his attitude towards Governor Eyre, are generally regarded as the main causes of his defeat in the general election of 1868. But, as he suggests himself, his studied advocacy of unfamiliar projects of reform had made him unpopular with "moderate Liberals." He retired with a sense of relief to his cottage and his literary life at Avignon. His parliamentary duties and the quantity of correspondence brought upon him by increased publicity had absorbed nearly the whole of his time. The scanty leisure of his first success had been devoted to writing his St Andrews rectorial address on higher education and to answering attacks on his criticism of Hamilton; of the second, to annotating in conjunction with Bain and Findlater, his father's Analysis of the Mind. Now he looked forward to a literary life, and his correspondence with his friends and to his literary work. His little cottage was filled with books and newspapers; the beautiful country round it furnished him with a variety of walks; he read, wrote, discussed, walked, botanized. He was extremely fond of music and was himself a fair pianist. His step-daughter, Miss Taylor (d. January 1907), was his constant companion after his wife's death. "Helen," he wrote to W. T. Thornton, an old colleague in the India House, "has carried out her long-cherished scheme (about which she tells me she consulted you) of a 'vibratory' for me, and has made a pleasant covered walk, some 30 ft. long, where I can vibrate in cold or rainy weather. The terrace, you must know, as it goes round two sides of the house, has got itself

XVIII. 15 a
MILL, JOHN STUART
dubbed the ‘semi-circumjacent.’ In addition to this, Helen has built me a herbarium, a little room fitted up with closets for my plants, shelves for my botanical books, and a great table where to manipulate them all. Thus, you see, with my herbarium, my vibratory, and my semi-circumjacent, I am in clover; and you may imagine with what scorn I think of the House of Commons, which, comfortable club as it is said to be, could offer me none of these comforts, or, more perfectly speaking, these necessaries of life.” Mill was an enthusiastic botanist all his life long, and a frequent contributor of notes and short papers to the *Phytologist*. One of the things that he looked forward to during his last journey to Avignon was seeing the spring flowers and the herbarium in the locality. His enjoyment in science frequently appears in letters written to his friends during his summer and autumn tours.

Yet he did not relax his laborious habits nor his ardent outlook on human affairs. The essays in the fourth volume of his *Dissertations*—on endomorphies, on land, on labor, on metaphysical and psychological questions—were written for the *Fortnightly Review* at intervals after his short parliamentary career. One of his first tasks was to send his treatise on the *Subject of Women* (written 1854, published 1859, many editions) to the press. Though it was a failure in most quarters, the last public work in which he engaged was the starting of the Land Tenure Reform Association. The exception by the state of the unlearned increment, and the promotion of co-operative agriculture, were the most striking features in his programme. He wrote in the *Examiner* and made a public speech in favour of the association a few months before his death. The secret of the arduous with which he took up this question probably was his conviction that a great struggle was impending in Europe between labour and capital. He regarded this subject as a timely compromise on two points of view. His references to his friends were always generous, and he was always ready to assist those whose work needed help. For example, he desired to guarantee the cost of the first books of Bain and Herbert Spencer. A statue in bronze was placed on the Thames Embankment, and there is a good portrait by Whistler (a copy of which, by Watts himself, was hung in the National Gallery).

The influence which Mill’s works exercised upon contemporary English thought can scarcely be overestimated. His own writings and those of his successors (e.g. J. E. Cairnes and Alexander Bain) have formed one of the cornerstones of philosophy for a century and even later. In philosophy his chief work was to systematize and expound the utilitarianism of his father and Bentham (see *Utilitarianism*). He may, in fact, be regarded as the author of that empirical school of philosophy which owed its impulse to John Locke, and is generally spoken of as being typically English. Its fundamental characteristic is the emphasis laid upon human reason, i.e. upon the duty incumbent upon all thinkers to investigate for themselves rather than to accept the authority of others. Knowledge must be based upon experience. In reasserting and amplifying the empirical conclusions of his predecessors, especially in the realm of ethics, Mill’s chief function was the introduction of the humanist element. This was due, no doubt, to his revulsion from the sternness of his upbringing and the period of stress through which he passed in early manhood, but it is also due to the intellectual bent and emotional qualities which manifested themselves in his early manhood. We have seen, for example, that he was led to investigate the subject of language because he found in attempting to advance his humanitarian schemes in politics an absence of that fundamental agreement which he recognized as the basis of scientific advance. Both his logical and his metaphysical studies were thus undertaken as the pre-requisites of a project of social development. Indeed, Mill’s writings have shown that the lower classes were not yet ripe for socialism, with the principles of which he (unlike James Mill and Bentham) was in general agreement, his whole life devoted to the amelioration of the conditions of the working classes. This fact, however, no doubt should be taken into account in any detailed criticism of the philosophic work; it was taken up not as an end but as ancillary to a social and ethical system. Reference is made on Logic, Ethics, &c., will show that significant criticism, however much it has overstepped the limits of Mill’s strenuous rationalism, has been able to point to much that is inconsistent, inadequate and even superficial in his writings. Two main intellectual movements from widely different standpoints have combined to diminish his influence. On the one hand there has arisen a school of thinkers of the type of Thomas Hill Green, who have brought the problems of utilitarianism to a much greater degree of specularity than Mill himself; on the other hand are the evolutionists, who have substituted for the utilitarian ideal of the ‘greatest happiness’ those of ‘race-preservation’ and the ‘survival of the fittest’ in its physiological and psychological sense. In the sphere of psychology, likewise—e.g. in connexion with Mill’s doctrine of Association of Ideas (q.v.)—and the phrase “Mental Chemistry,” by which he sought to deal with the problems of associationism—modern criticism and the experimental methods of the physiological school have set up wholly new criteria, with a new terminology and different fields of investigation (see *Psychology*). A similar fate has befallen Mill’s economic theories. The title of his work, *Principles of Political Economy*, with some of their Applications to Social Philosophy, though open to criticism, indicated an attempt to bring together and develop the fundamental principles of the subject with their applications, and in treating those applications had perpetually appealed to other and often far larger considerations than pure political laws. Of the same order was his work on *England* and *France*, in which he offered to the student a general survey of the fields of the sciences which had been common amongst his predecessors. He aimed in fact at producing a work which might replace in ordinary use the *Wealth of Nations*, which in his opinion was “in many parts obsolete and a distortion of two sorts of economic inquiry, with the Malthian theory being of course incorporated with these; but, notwithstanding the introduction of many minor novelties, it is in its scientific substance little more than a method to connect economic method he shifted his position, yet to the end occupied uncertain ground. In the fifth of his early essays he asserted that the method a priori is the only mode of investigation in the social sciences, and that “social science is altogether indiscernible in those sciences as a means of arriving at any considerable body of valuable truth.” When he wrote his *Logic* he had learned from Comte that the a priori methods which he considered the only mode of arriving at truth in general sociology, and his admission of this at once renders his essay obsolete. But, unwilling to relinquish the a priori method of his youth, he tries to establish a compromise between the two. His reference to political economy is a part of “social philosophy” at all, and not rather a study preparatory and auxiliary to it. Thus, on the logical as well as on the dogmatic side of his work, he has been criticized for discrediting those principles of the “classical utilitarianism” which he himself had so strongly advocated, and for having sought to replace them by a “classical” system of utilitarianism and a “classical” system of sociological method. But the title of his systematic work implies a doubt whether political economy is a part of “social philosophy” at all, and not rather a study preparatory and auxiliary to it. Thus, on the logical as well as on the dogmatic side of his work, he has been criticized for discrediting those principles of the “classical utilitarianism” which he himself had so strongly advocated, and for having sought to replace them by a “classical” system of utilitarianism and sociological method.

Biographical and Critical.—Many of Mill’s letters are published in *Letters of John Stuart Mill* (ed. by his wife, Helen), *Letters of John Stuart Mill*, 1837–1880). There are also editions of the correspondence with Gustave d’Eichthal and Comte (especially that of Lvvy-Bruhl, 1890). By far the most important work on Mill is the *Biography* by W. B. C. F. Spence, in *Letters of John Stuart Mill*, 1837–1880 (ed. by his wife, Helen), *Letters of John Stuart Mill*, 1837–1880). There are also editions of the correspondence with Gustave d’Eichthal and Comte (especially that of Lvvy-Bruhl, 1890). By far the most important work on Mill is the *Biography* by W. B. C. F. Spence, in *Letters of John Stuart Mill*, 1837–1880. A convenient edition in the New Universal Library appeared between 1905 and 1910.

MILL (O. Eng. myn, later myin, or millin, adapted from the late Lat. mollina, cf. Fr. moulin, from Lat. molina, a mill, molere, to grind; from the same root, mol, is derived "meal," the word appears in other Teutonic languages, cf. Du. molen, Ger. mühle), the building in which the power is applied to the grinding of corn into flour, and hence applied to similar mechanical devices for grinding, crushing to powder, or pulping other substances, e.g. coffee-mill, powder-mill. "Mill" was first used of the building containing the apparatus, frequently with a word attached descriptive of the motive power, e.g. wind-mill, water-mill, &c.

It was not the early word used of the actual grinding mechanism. The old hand-mill was known as a "quern," a word which appears in this sense in many Indo-European languages; the ultimate root is ger-, to grind. "Quern" (see Fr. quern) remains connected with "milling," and the word is also applied to many mechanical devices by which raw material is transformed into a condition ready for use or into a stage preparatory to other processes, e.g. saw-mill, rolling-mill, &c., or still more widely to buildings containing machinery used in manufactures, e.g. cotton-mill. In mining it is applied to various machines used in breaking and crushing the ore (see Ore-dressing).

In the engineering industries milling machines constitute a very important class of machine tools, the characteristic of which is that rotary cutting is employed in the grinding process. The term "milling" is the most generally adopted for this "creepling" by John Evelyn (Discourse on Melons, 1607, p. 225), which is formed on them to prevent clipping and filling. Coins made by the old process of hammering were apt to have irregular edges which invited mutilation; but the introduction of the screw press, which came to be known as a mill (cf. W. Lowndes, Amendm. Silver Coinage, 1605, p. 93), permitted the production of a regular edge with serrations, which in consequence were termed milling. This machine also enabled legends to be impressed round the edges of coins, such as "Mary the Queen," and was connected with "milling," and more generally, "milling." (See Hocking, Catalogue of the Coins, &c., in the Museum of the Royal Mint, 1906). It was invented about the middle of the 16th century, and has generally been attributed to Guyot Brucher (d. 1550), who was succeeded at the Paris mint by his brother Antoine. Introduced into England by one Eloye Mestrel in 1561, it was used for twelve years, and was then abandoned owing to the opposition of the mint officials to Mestrel, who was executed for counterfeiting and striking money outside the precincts of the Tower of London; but it was again introduced by one Peter Blondeau in 1562, when it prevailed in the grinding of hammering. In the United States of America the term "milling" or "milled" is applied to the raised edge on the face of the coin; this is known in the British mint as "marking" (see Mint). John William Millais, who belonged to an old Norman family settled in Jersey for many generations, and Emily Mary, née Evamy, the widow of a Mr Hodgkinson. After his birth the family returned to Jersey, where the boy soon began to sketch. At the age of eight he drew his maternal grandfather. He went to school for a short time, but showed no inclination for study, and was afterwards educated entirely by his father. In 1855 the family removed to Dieppe in Brittany, where he sketched for the French officers, to their great amusement, and in 1837, on the family's return to Jersey, he was taught drawing by a Mr Büssel.

In 1838 he came to London, and on the strong recommendation of Sir Martin Archer Shee, P.R.A., his future was decided. He was sent at once to Sass's school, and entered the Academy schools in 1840. He won a silver medal from the Society of Arts in 1839, and carried off all the prizes at the Royal Academy. He was popular amongst the students, and was called "the child," because he wore his boyish costume till long after the usual age. In 1840 and the immediately succeeding years he made the acquaintance of Wordsworth and other interesting and useful people. He was at this time painting small pictures, &c., for a dealer named Thomas, and defraying a great part of the household expenses in Gowar Street, where his family lived.

In 1846 he exhibited "Pizarro seizing the Inca of Peru" at the Royal Academy, and in 1847 "Eligiva seized by the Soldiers of Odo." In the latter year he competed unsuccessfully at the exhibition of designs for the decoration of the Houses of Parliament, and among a series of pictures painted for the Swiss Consulate, which was afterwards cut up. In the beginning of 1848 he and W. Holman Hunt, dissatisfied with the theory and practice of British art, which had sunk to its lowest and most conventional level, initiated what is known as the Pre-Raphaelite movement, and were joined by Dante Gabriel Rossetti, and afterwards by five others, altogether forming the Pre-Raphaelite Brotherhood. Rossetti was then engaged, under the technical guidance of Hunt, upon his picture of "The Girlhood of Mary Virgin," which, with Holman Hunt's "Light of the World" and Millais's "Christ in the House of His Parents," forms what has been called the trilogy of Pre-Raphaelite art. According to Millais, the Pre-Raphaelites had but one idea—"to present on canvas what they saw in Nature." Millais's first picture on his new principles was a banquet scene from Keats's "Isabella" (1849), and contains all the characteristics of Pre-Raphaelite work, including minute imitation of nature down to the smallest detail, and the study of all persons and objects directly from the originals. The tale was told with dramatic force, and the expression of the heads was excellent. His next important picture, "Christ in the House of His Parents," won the New Orleans Centenary Silver Medal Exhibition (1859), represented a supposed incident in the childhood of Our Lord treated in a simply realistic manner, and drew upon him a storm of abuse from nearly all quarters, religious and artistic. The rest of his more strictly Pre-Raphaelite pictures—"The Return of the Dove to the Ark," "The Woodman's Daughter" and the "Mariana" of 1851, "The Huguenot" and "Ophelia" of 1852, "The Proscribed Royalist" and "The Order of Release" of 1853—met with less opposition, and established his reputation with the public. Indeed, this may be said to have been accomplished by the public reception of "The Return of the Dove." He was now called the "Young Whitewash;" the Whitewash's" &c. The public were also greatly influenced by the splendid championship of Ruskin, who, in letters to The Times, and in a pamphlet called "Pre-Raphaelitism," enthusiastically espoused the cause of the Brotherhood. In 1857 Millais, who had refused to read Modern Painters, where the supposed principles of the Brotherhood were first recommended, became acquainted with Ruskin, and in 1853 went to Scotland with him and Mrs Ruskin, the latter of whom sat for the woman in "The Order of Release." He made several designs for Ruskin, and painted his portrait. In 1855 Millais exhibited "The Rescue," a scene from a novel which drew great attention, from the frantic expression of the mother and the brilliant painting of the glare. In the Paris Exhibition of this year he was represented by "The Order of Release," "Ophelia" and "The Return of the Dove." This was also the
of 1878, where it was sent with "Chill October," and three others of his pictures. But perhaps the works of his later years by which he will be most remembered are his portraits—especially his three portraits of Gladstone (1879, 1883 and 1890), and those of John Bright, of Lord Tennyson, and of Lord Beaconsfield, which was left unfinished at his death. He also painted the marquess of Salisbury, Lord Rosebery, the dukes of Devonshire and Argyll, Cardinal Newman, Thomas Carlyle, Sir James Paget, Sir Henry Irving, George Grote, Lord Chief Justice Russell, J. C. Hook, R.A., and himself (Ufford Gallery, Florence). He represented, for instance, a gentleman, a peasant, a doctor, a lawyer, and his other portraits of women were those of Mrs Bischoffsheim, the duchess of Westminster, Lady Campbell and Mrs Jopling.

No very serious interruption of his usual life as a prosperous English gentleman occurred in these years, except the death of his second son, George, in 1878. In 1875 he went to Holland, one of his few visits to the Continent. In 1879 he left Cromwell Place for a house at Palace Gate, Kensington, which he built, and where he died. In 1885 he was created a baronet, on the suggestion of Mr Gladstone. In 1892 his health began to break. He was attacked by a bad attack of influenzal pneumonia, and was marked with swelling in his throat, which proved to be due to cancer. He suffered much from depression, but worked when he could, and derived much pleasure in painting several pictures, including "St Stephen," "A Disciple," "Speak! Speak!" which was bought out of the Chantrey Bequest, and "The Forerunner"—his last exhibited subject-picture. His finely-characterized portraits of Mr John Hare, the actor, and Sir Richard Quain belong also to his last years. In 1895, in consequence of the illness of Lord (then Sir Frederick) Leighton, he was called upon to preside at the annual banquet of the Royal Academy, and on the death of Lord Leighton he was elected to the presidential chair. He died on the 12th of August 1896, and was buried in St Paul's Cathedral. The Winter Exhibition of the Royal Academy in 1898 was devoted to his works. The list of his honours at home and abroad is a long one. Millais was one of the greatest painters of his time, and did more than any other to infuse a new and healthy life into British art. He had not the imagination of an idealist, but he could paint what he saw with a force which has seldom been exceeded. As a man he was manly, frank and genial, devoted to his art and his family, and very fond of sport, especially hunting, fishing and shooting. He was greatly loved by a very large circle of friends. He was singularly handsome, and had a fine presence. The National Gallery of British Art possesses many of his finest works. He is also represented in the National Gallery, in the National Portrait Gallery, the Victoria and Albert Museum, and in the public galleries at Manchester, Liverpool and Birmingham.

**MILLAN, ANDREW** (1707-1768), British publisher, was born in 1707. About 1729 he started business as a bookseller and publisher in the Strand, London. His own judgment in literary matters was small, but he collected an excellent staff of literary advisers, and did not hesitate to pay what at the time were considered large prices for good material. "I respect Millar, sir," said Dr Johnson in 1755, "he has raised the price of literature. He paid Thacker £105 for The Seasons, and Fielding a total sum of £60 for Tom Jones and Robinson Crusoe." He was one of the syndicate of booksellers who financed Johnson's Dictionary, and on him the work of seeing that book through the press mainly fell. He also published the histories of Robertson and Hume. He died at his villa at Kew Green, near London, on the 8th of June 1768.

**MILLAU,** a town of southern France, capital of an arrondissement in the department of Aveyron, on the right bank of the Tarn at its confluence with the Daurbie, 74 m. N. of Béziers on the southern railway. Pop. (1900), 16,853. Millau lies in a
rich valley 1200 ft. above the sea surrounded by the spurs of the Levezu, Causee Noir and Laarzae ranges. The streets are narrow and some of the houses of great antiquity, but the town is surrounded by spacious boulevards. One of its squares is bordered on two sides by wooden galleries supported on stone columns. The only buildings of special interest are the Romanesque church of Notre Dame, restored in the 16th century, and the fine Gothic building of the old hotel de ville. Milau is seat of a sub-prefect, and possesses tribunals of first instance and of commerce, a board of trade-arbitrators, a chamber of commerce and a communal college. The principal industry is the manufacture of gloves, and various branches of the leather industry are carried on. The chief articles of trade are skins, wool, wine and Roquefort cheese.

In the middle ages Milau was the seat of a viscountcy held by the counts of Barcelona and afterwards by the counts of Armagnac. In the 16th century it became one of the leading strongholds of Calvinism in southern France. In 1609 it revolted against Louis XIII., and after its submission Richelieu caused its fortifications to be dismantled. The edict of Nantes hastened the decline of the town, which did not recover its prosperity till after the Revolution.

MILLBURY, a township of Worcester county, Massachusetts, on the Blackstone river, 5 m. S.S.E. of Worcester. Pop. (1890), 4428; (1900) 4460 (1767 foreign-born); (1905, state census) 4631; (1910) 4740. Area, 15.7 sq. m. Millbury is served by the New York, New Haven & Hartford, and the Boston & Albany railways, and by electric interurban railways. It lies for the most part in the valley of the Blackstone river, from which water-power is derived for its mills; among its manufactures are cotton, linen, felt and woolen goods, hemp thread, and foundry and machine-shop products. The municipality owns and operates the waterworks and electric-lighting plant. Millbury was formed in 1813 from the North Parish of Sutton; in 1851 a part of Auburnd was annexed to the township.

MILLEDGEVILLE, a city and the county-seat of Baldwin county, in the central part of Georgia, U.S.A., on the Oconee river, at the head of navigation, 32 m. E.N.E. of Macon. Pop. (1800), 3382; (1820), 4219, of whom 2663 were negroes. It is served by the Georgia and the Central of Georgia railways. Milledgeville is situated in the Cotton Belt, and its principal industry is the preparation of cotton for the markets. The importance of the place, however, is mainly educational and historical. It is the seat of the Middle Georgia Military and Agricultural College, which occupies the old capitol building, and of the Georgia Normal and Industrial College for girls (1859; enrolment 1908-1909, 653), which is a part of the University of Georgia, and occupies the site of the old state penitentiary. A public park, the central part of Milledgeville, is the state juvenile reformatory; 2 m. south of the city are the state asylums for white and negro insane; and 3 m. north-west is the state prison farm. Milledgeville was founded in 1803, and was named in honour of John Milledge (1757-1818), a representative in Congress in 1792-1793 and 1795-1802, governor of Georgia in 1802-1806, a United States senator in 1806-1809, and a benefactor of the state university. In 1804 it was made the seat of the state government in place of Louisville (capital in 1795-1804; pop. in 1900, 1900), a dignity it held until 1806. The city was first chartered in 1836. Although admirably situated for trade and manufacturing, Milledgeville was suppressed in both by Macon, which became the commercial emporium of middle Georgia; but it was a favourite place of residence for the wealthy and cultivated class of Georgians before the Civil War. It was seized by General William T. Sherman on the 23rd of November 1864. In order to remove the state documents beyond reach of the enemy, Governor Joseph E. Brown called upon the convicts in the penitentiary for aid, granting them pardons in return for their services.

MILLENIUM (a pseudo-Latin word formed on the analogy of Neronian, Armeniac, French Mille, a thousand, and annus, year), literally a period of a thousand years. The term is specially used of the period of 1000 years during which Christ, as has been believed, would return to govern the earth in person. Hence it is used to describe a vague time in the future when all laws in human existence will have vanished, and perfect goodness and happiness will prevail. The attribution of a mystical significance to the millennium-period, though perhaps not prominent in that theory of Christian eschatology to which the names Millenarianism and Chiliasm (from Gr. χίλια, a thousand) are given, is quite common in non-Christian religions and cosmological systems.

Faith in the nearness of Christ's second advent and the establishing of his reign of glory on the earth was undoubtedly a strong point in the primitive Christian Church. In the anticipations of the future prevalent amongst the early Christians (c. 50-150) it is necessary to distinguish a fixed and a fluctuating element. The former includes (1) the notion that a last terrible battle with the enemies of God was impending; (2) the faith in the speedy return of Christ; (3) the conviction that Christ will judge all men and (4) will set up a kingdom of glory on earth.

To the latter belong views of the Antichrist, of the heavenly world-power, of the place, extent, and duration of the earthly kingdom of Christ, &c. These remained in a state of solution; they were modified from day to day, partly because of the changing circumstances of the present by which forecasts of the future were regulated, partly because the indications—real or supposed—of the ancient prophets always admitted of new combinations and constructions. But even here certain positions were agreed on in large sections of Christendom. Amongst these was the conviction that the future kingdom of Christ on earth should have a fixed duration, according to the most prevalent opinion, a duration of one thousand years. From this fact the whole ancient Christian eschatology was known in later times as "chiliasm"—a name which is not strictly accurate, since the doctrine of the millennium was only one feature in its scheme of the future.

1. This idea that the Messianic kingdom of the future on earth should have a definite duration has—like the whole eschatology of the primitive Church—its roots in the Jewish apocalyptic literature, where it appears at a comparatively late period. At first it was assumed that the Messianic kingdom in Palestine would last for ever (so the prophets; cf. Jer. xxiv. 6; Ezek. xxxvii. 25; Joel iv. 20; Dan. vii. 27; Sibyl. iii. 49 seq.; 766; Ps. xlv. xiv. 4; Enoch xi. 14), and this seems always to have been the most widely accepted view (John xii. 34). But from a comparison of prophetic passages of the Old Testament learned apocalyptic writers came to the conclusion that a distinction must be drawn between the earthly appearance of the Messiah and the appearance of God Himself amongst His people in the Gentile world for the final judgment. As a necessary consequence, a limited period had to be assigned to the Messianic kingdom. According to the Apocalypse of Baruch (xl. 3) this kingdom will last "donae finitum mundus corruptionibus." In the Book of Enoch (xcl. 12) "a week" is specified, in the Apocalyptic of Ezra (vii. 28 seq.) four hundred years. This figure, corresponding to the four hundred years of Egyptian bondage, occurs also in the Talmud (Sanhedrin 99c). But this is the only passage; the Talmud has no fixed doctrine on the point. The view most frequently expressed there (see Von Otto In Hilligenfeld's Zeitschrift, 1877, p. 537 seq.) is that the Messianic kingdom will last for one thousand years (some said two thousand years). "In six days God created the world, on the seventh He rested. But a day of God is equal to a thousand years (Ps. xc. 4). Hence the world will last for six thousand years of toil and labour; then will come one thousand years of Sabbath rest for the people of God in the kingdom of the Messiah." This idea must have already been very common in the first century before Christ. The combination of Gen. r, Dan. ix. and Ps. xc. 4 was peculiarly fascinating.

Nowhere in the discourses of Jesus there is hint of a limited duration of the Messianic kingdom. The apostolic epistles are equally free from any trace of chiliasm (neither 1 Cor. xv. 23 seq. nor 1 Thess. iv. 16 seq. points in this direction). In Revelation, however, it occurs in the following shape (ch. xx.). After
Christ has appeared from heaven in the guise of a warrior, and vanquished the antichristian world-power, the wisdom of the world, and the devil, those who have remained steadfast in the time of the last catastrophe, and have given up their lives for their faith, shall be raised up, and shall reign with Christ on this earth as a royal priesthood for one thousand years. At the end of this time Satan is to be let loose again for a short season; he will prepare a new onslaught, but God will miraculously destroy him and his hosts. Then will follow the general resurrection of the dead, the last judgment, and the creation of new heavens and a new earth. That all believers will have a share in this resurrection of the dead, the Messianic kingdom, is an idea of which the author of Revelation knows nothing. The earthly kingdom of Christ is reserved for those who have endured the most terrible tribulation, who have withstood the supreme effort of the world-power—that is, for those who are actually members of the church of the last days. The Jewish expectation is thus considerably curtailed, as it is also shorn of its sensual attractions. “Blessed and holy is he that hath part in the first resurrection; on such the second death hath no power; but they shall be priests of God and of Christ, and shall reign with Him a thousand years.” Barnabas ( adopted the Jewish apocalypses as sacred books of venerable antiquity, they read them eagerly, and transferred their contents bodily to Christianity. Nay more, the Gentile Christians took possession of them, and just in proportion as they were neglected by the Jews—who, after the war of Bar-Cochba, became indifferent to the Messianic hope and hardened themselves once more in devotion to the law—they were naturalized in the Christian communities. The result was that these books became “Christian” documents; it is entirely to Christian, not to Jewish, tradition that we owe their preservation. The Jewish expectations are adopted for example, by Papias, by the writer of the epistle of Barnabas, and by Justin. Papias actually confounds expressions of Jesus with verses from the Apocalypse of Baruch, referring to the amazing fertility of the days of the Messianic kingdom (Papias in Iren. v. 33). Barnabas (Ep. 15) gives us the Jewish theory (from Gen. i, Ps. xc. 4) that the present condition of the world is to last six thousand years from the creation, that at the beginning of the Sabbath (the seventh millennium) the Son of God appears, to put an end to the time of “the unjust one,” to judge the ungodly and renew the earth. But he does not indulge, like Papias, in sensuous descriptions of this seventh millennium; to Barnabas it is a time of rest, of sinlessness, and of a holy peace. It is not the end, however; it is followed by an eighth day of eternal duration—the beginning of another world.” So that in the view of Barnabas the Messianic reign still belongs to οὕτως δ ἄδων. Justin ( Dial. 80) speaks of chiliasm as a necessary part of complete orthodoxy, although he knows Christians who do not accept it. He believes, with the Jews, in a restoration and extension of the city of Jerusalem; he assumes that this city will be the seat of the Messianic kingdom, and he takes it as a matter of course that there all believers (here he is at one with Barnabas) along with patriarchs and prophets will enjoy perfect felicity for one thousand years. That a philosopher like Justin, with a bias toward an Hellenic construction of the Christian religion, should nevertheless have accepted its chilastic elements is the strongest proof that these enthusiastic expectations were inseparably bound up with the Christian faith from the very beginning. And another proof is found in the fact that even a speculative Jewish Christian like Cerinthus not only did not renounce the chilastic hope, but pictured the future kingdom of Christ as a kingdom of sensual pleasures, of eating and drinking and marriage festivities (Euseb. H. E. iii. 28, vii. 25).

After the middle of the 2nd century these expectations were gradually thrust into the background. They would never have died out, however, had not circumstances altered, and a new movement have been taken up. The spirit of philosophical and theological speculation and of ethical reflection, which began to spread through the churches, did not know what to make of the old hopes of the future. To a new generation they seemed paltry, earthly and fantastic, and far-seeing men had good reason to regard them as a source of political danger. But more than this, these wild dreams about the glorious kingdom of Christ began to disturb the organization which the churches had seen fit to introduce. In the interests of self-preservation against the world, the state and the heretics, the Christian communities had formed themselves into compact societies with a definite creed and constitution, and they felt that their existence was threatened by the white heat of religious subjectivity. So early as the year 170, a church party in Asia Minor the so-called “adversaries” of the body of apocalyptic writings and denounced the book of Revelation as a book of fables. All the more powerful was the reaction. In the so-called Montanist controversy (c. 160–220) one of the principal issues involved was the continuance of the chiliasm expectations in the churches. The Montanists of Asia Minor defended them in their integrity, with only one modification: they announced that Pepusa, the city of Montanus, would be the site of the New Jerusalem and the millennial kingdom. After the Montanist controversy chiliasm views were more and more discredited in the Greek Church; they were, in fact, stigmatized as “heretical.” It was the Alexandrian theology that superseded them; that is to say, Neoplatonic mysticism triumphed over the early Christian hope of the future, first among the “cultured,” and then, when the theology of the “cultured” had taken the faith of the “uncultured” under its protection, amongst the latter also. About the year 260 an Egyptian bishop, Nepos, in a treatise called Ἠγεγορία η Ἀληθείαν, endeavored to overthrow the Origenistic theology and vindicate chiliasm by exegetical methods. Several congregations took his part; but ultimately Dionysius, bishop of Alexandria, succeeded in healing the schism and asserted the allegorical interpretation of the prophets as the only legitimate exegesis. During this controversy Dionysius became convinced that the victory of mystical theology over “Jewish” chiliasm would never be secure so long as the book of Revelation passed for an apostolic writing and kept its place among the homologomena of the canon. He accordingly raised the question of its apostolic origin; and by reviving old difficulties, with ingenious arguments of his own, he carried his point. At the time of Eusebius the Greek Church was saturated with prejudice against the book and with doubts as to its canonicity. In the course of the 4th century it was removed from the Greek canon, and thus the troublesome foundation on which chiliasm might have continued to build was got rid of. The attempts of Methodius of Tyre at the beginning of the 4th century and Apollinaris of Laodicea about 360 to defend chiliasm and assail the theology of Origen had no result. For many centuries the Greek Church kept Revelation out of its canon, and consequently chiliasm remained in its grave. It was considered a sufficient safeguard against the spiritualizing eschatology of Origen and his school to have rescued the main doctrines of the creed and the regula fidei (the visible advent of Christ; eternal misery and hell-fire for the wicked). Anything beyond this was held to be Jewish. It was only the chronologists and historians of the church who, following Julius Africanus, made use of apocalyptic numbers in their calculations, while court theologians like Eusebius entertained the imperial table with discussions as to whether the dining-hall of the emperor—the second David and Solomon, the beloved of God—might not be the New Jerusalem of John’s Apocalypse. Eusebius was not the first who dabbed in such speculations. Dionysius of Alexandria had already referred a Messianic prediction of the Old Testament to the emperor Constantius. But mysticism and political servility between them gave the death-blow to chiliasm in the Greek Church. It never again obtained a footing there; for, although, late in the middle ages, the book of Revelation—by what means we cannot tell—did recover its authority, the Church was by that time so hopelessly trammeled by a magical cultus as to be incapable of fresh developments. In the Semitic churches of the East (the Syrian, Arabian and Ethiopian), and in that of Armenia, the apocalyptic literature was preserved much longer than in the Greek Church. They were very conservative of ancient traditions in general, and hence
chiliasm survived amongst them to a later date than in Alexandria or Constantinople.

But the Western Church was also more conservative than the Greek. Her theologians had, to begin with, little turn for mystical speculation; their tendency was rather to reduce the gospel to a system of morals. Now for the moralists chiliasm had a special significance as the one distinguishing feature of the gospel, and the only thing that gave a specifically Christian character to their system. This, however, holds good of the Western theologians only after the middle of the 3rd century. The earlier fathers, Irenaeus, Hippolytus, Tertullian, believed in chiliasm simply because it was an etymology, and because Marcion and the Gnostics would have nothing to do with it. Irenaeus (v. 28, 29) has the same conception of the millennial kingdom as Barnabas and Papias, and appeals in support of it to the testimony of disciples of the apostles. Hippolytus, although an opponent of Montanism, was nevertheless a thorough-going millenarian (see his book De Antichristo), Tertullian (cf. especially Adv. Marcion., 3) aimed at a more spiritual conception of the millennial blessings than Papias had, but he still adhered, especially in his Montanistic period, to all the ancient anticipations. It is the same all through the 3rd and 4th centuries; the Latin Fathers and the East were in accord, and the influence of Greek speculation, Commodian, Victorinus Pettenvastus, Lactantius and Sulpicius Severus were all pronounced millenarians, holding by the very details of the primitive Christian expectations. They still believe, as John did, in the return of Nero as the Antichrist; they still expect that after the first resurrection Christ will reign with his saints "in the flesh" for a thousand years. Once, but only once (in the Gospel of Nicodemus), the time is reduced to five hundred years. Victorinus wrote a commentary on the Apocalypse of John; and all these theologians, especially Lactantius, were diligent students of the ancient Sibyl. Later oracles of Jewish and Christian origin, and treated them as divine revelations. As to the canonicity and apostolic authorship of the Johannine Apocalypse no doubts were ever entertained in the West; indeed an Apocalypse of Peter was still retained in the canon in the 3rd century. That of Ezra, in its Latin translation, must have been all but a canonical book—the numbers of extant manuscripts of the so-called 4 Ezra being incredibly great, while several of them are found in copies of the Latin Bible at the beginning of the 16th century. The Apocalypse of Hermas was much read till far through the middle ages, and has also kept its place in some Bibles. The apocalyptic "Testamenta duodecim patriarcharum" was a favourite reading-book; and Latin versions of ancient apocalypses are being continually brought to light from Western libraries (e.g. the Assumptio Mosis, the Ascensio Jesuæ, &c.). All these facts show how vigorously the early hopes of the future maintained themselves in the West. In the hands of moralistic theologians, like Lactantius, they certainly assume a somewhat grotesque form, but the fact that these men clung to them is the clearest evidence that in the West millenarianism was still a point of "orthodoxy" in the 4th century.

This state of matters, however, gradually disappeared after the end of the 4th century. The change was brought about by two causes—first, Greek theology, which reached the West chiefly through Jerome Rufinus and Ambrose, and, second, the new idea of the church wrought out by Augustine on the basis of the altered political situation of the church. Augustine was the first who ventured to teach that the catholic church, in its empirical form, was the kingdom of Christ, that the millennial kingdom had commenced with the appearing of Christ, and was therefore an accomplished fact. By this doctrine of Augustine's, the old millenarianism, though not completely extirpated, was at least banished from the official theology. It still lived on, however, in the lower strata of Christian society; and in certain undercurrents of tradition it was transmitted from century to century. At various periods in the history of the middle ages we encounter sudden outbreaks of millenarianism, sometimes as the tenet of a small sect, sometimes as a far-reaching movement. And, since it had been suppressed, not, as in the East, by mystical speculation, its mightiest antagonist, but by the political church of the hierarchy, we find that wherever chiliasm appears in the middle ages it makes common cause with all enemies of the secularized church. It strengthened the hands of church democracy; it formed an alliance with the pure souls who held up to the church the ideal of apostolic poverty; it united itself for a time even with mysticism in a common opposition to the supremacy of the church; nay, it lent the strength of its convictions to the support of states and princes in their efforts to break the political power of the church. It is sufficient to recall the well-known names of Joachim of Floris, of all the numerous Franciscan spiritualists, of the leading sectaries from the 13th to the 16th century who assailed the papacy and the secularism of the church—above all, the name of Tertullian. In these men the millenarianism of the ancient church came to life again; and in the revolutionary movements of the 15th and 16th centuries—especially in the Anabaptist movements—it appears with all its old uncompromising energy. If the church, and not the state, was regarded as Babylon, and the pope declared to be the Antichrist, these were legitimate inferences from the ancient traditions and the actual position of the church. But, of course, the new chiliasm was not in every respect identical with the old. It ceased to hold its ground without admitting certain innovations. The "everlasting gospel" of Josephus is nothing but another thing from the announcement of Christ's glorious return in the clouds of heaven; the "age of the spirit" which mystics and spiritualists expected contained traits which must be characterized as "modern"; and the "kingdom" of the Anabaptists in Münster was a Satanic caricature of that kingdom in which the Christians of the 2nd century looked for a peaceful Sabbath rest. Only we must not form our ideas of the great apocalyptic and chilismatic movement of the first decades of the 16th century from the rabble in Münster. There were pure evangelical forces at work in it; and many Anabaptists need not shun comparison with the Christians of the apostolic and post-apostolic ages.

The German and Swiss Reformers also believed that the end of the world was near, but they had different aims in view from those of the Anabaptists. It was not from poverty and apocalypticism that they hoped for a reformation of the Church. In contrast to the fanatics, after a brief hesitation they threw millenarianism overboard, and along with it all other "opinions Judaicae." They took up the same ground in this respect which the Roman Catholic Church had occupied since the time of Augustin. How millenarianism nevertheless found its way, with the help of apocalyptic mysticism and Anabaptist influences into the churches of the Reformation, chiefly among the Reformed sects, but afterwards also in the Lutheran Church, how it became incorporated with Pietism, how in more recent times an exceedingly mild type of "academic" chiliasm has been developed in a belief in the verbal inspiration of the Bible, how finally new sects are still springing up here and there with apocalyptic and chilismatic expectations—these are matters which cannot be fully entered upon here. See also CHILISM; Eschatology, and works there quoted.

MILLER, HUGH (1827-1850), Scottish geologist and man of letters, was born in humble circumstances at Cromarty, on the 10th of October 1822; his father, Hugh Miller, a seaman, was drowned when he was but five years old. His primary education was acquired at a dame's school and afterwards at the parish school, and at the age of six he had learned that "the art of reading is the art of finding stories in books." At the age of twelve he began to write verses. Two of his mother's brothers, James and "Sandy" Wright, hard-working men at Cromarty,
offered to assist him to enter the ministry, but he felt no call to the sacred office, and from 1826 to 1829 he was apprenticed to a stone-mason. During the next few years he obtained employment as a journeyman mason in Edinburgh, Inverness and various other parts of Scotland. The writing of verses occupied his leisure hours, and in 1826 he sent to the *Scotsman* an "Ode on Greece" which was refused. It was not until 1829 that he met with his first success in the publication of *Poems written in the Leisure Hours of a Journeyman Mason*. These were printed and issued from the press of the *Inverness Courier*. Miller now turned his attention to prose and contributed many essays to the *Inverness Courier*. As remarked by Sir A. Geikie, "These made so favourable an impression that they were soon afterwards reprinted separately. They marked the advent of a writer gifted with no ordinary powers of narration and with the command of a pure, nervous and masculine style."

At the age of thirty-two he was still a stone-mason, but in the latter part of 1834 he was offered a post as accountant in the Commercial Bank of Scotland, and was almost immediately transferred to the Cromarty branch. His prose writings had now attracted much notice, and he next issued in 1835 *Scenes and Legends of the North of Scotland, or the traditional history of Cromarty*, in which he introduced some memoranda on the geology. This work met with a cordial reception. Miller, while still a stone-mason, had observed the abundant fossils in the Jurassic shales on the shores of Etie, but it was not until 1839 that he first obtained remains of fossil fishes in the Old Red Sandstone. These for many years he collected and studied as far as he could, and in 1850 some of his specimens were brought to the notice of R. I. Murchison and Professor Agassiz. In the following year he was in communication with Murchison and his career as a geologist was definitely opened.

In 1837 Miller married Lydia Falconer Frazier (1817-1876), a lady of good position and great natural ability, whom he had met six years previously. He set up his household in Cromarty, on a salary of sixty pounds a year, aided by the small sums he then earned by literary work; and his wife took a few pupils. Mrs Miller eventually became well known under the pseudonym of Mrs Harriet Myrtle as author of the *Ocean Child* (1857) and other story-books for children.

Soon after his marriage, Miller became greatly stirred by the internal dissensions in the Church of Scotland, of which he was a staunch member, and he published two pamphlets which brought him to the notice of some of the prominent members of the liberal church party. In 1839 he went by invitation to Edinburgh to edit a new Whig newspaper, the *Witness*, which was intended to support the views of those who after the disruption in 1843 formed the Free Church. The paper rapidly attained a large circulation, and Miller soon won a largely due to his ability and scientific essays. In 1840 he contributed a series of articles on the *Old Red Sandstone*, and these were reprinted in book form in the following year. The charm of this work was widely appreciated, and was also the natural sagacity shown in the descriptions and restorations of some of the fossil fishes. His *Footprints of the Creator* was published in 1849, and *My Schools and Schoolmasters* in 1854. He was engaged on the final proofs of his *Testimony of the Rocks* on the day of his death. During the last year of his life he suffered from inflammation of the lungs and the strain of ill-health proving too severe, he died by his own hand in Edinburgh on the 23rd of December 1856. By request of his wife, the *Crise of the Betsey, with Ramble of a Geologist* (1858) previously printed only in the *Witness* newspaper was published under the editorship of the Rev. W. S. Symonds.

In memory of Hugh Miller a monument was erected by public subscription in 1860 at Cromarty; and the cottage in which he was born was acquired at a later period by his son Hugh. In it have been placed part of his library, a set of the *Witness* newspaper, some letters addressed to him, a number of geological specimens, including many referred to in his *Old Red Sandstone*. On the 22nd of August 1902 the centenary of his birth was celebrated at Cromarty, and was attended by scientific representatives from all parts of the world.

His eldest son, Hugh Miller (1850-1890), passed through the Royal School of Mines and joined the Geological Survey in England in 1873; afterwards he was transferred to Scotland and surveyed the country around Cromarty and other parts of Ross-shire and Sutherlandshire. He was author of *Landscape Geology*, 1871.

**Miller, Joaquin—Miller, W.**

American poet, was born in Indiana, on the 6th of November 1841, and was educated for the law. After some experiences of mining and journalism in Idaho and Oregon, he settled down in 1866 as judge in Grant county, Oregon, and during his four years' tenure of this post he began to write verse. In 1870 he travelled in Europe, and in 1871 he published his first volume of poetry; full of travel passion, *Songs of the Sierras*, on which his reputation mainly rests. His *Ode to the Sunlands* (1873) followed in the same vein, and after other volumes had appeared, his *Collected Poems* were published in 1882. He also wrote plays, *The Daughters in the Sierras* having some success as a sensational melodrama. On his return from Europe he became a journalist in Washington, but in 1887 returned to California. His pen-name, "Joaquin Miller," by which he is known, was assumed by him when he published his first book, in consequence of his having written an article in defence of Joaquin Murieta, the Mexican brigand.

Revised editions of his *Complete Poetical Works* appeared at San Francisco in 1902.

**Miller, Joe (Joseph or Josias) (1684-1738),** English actor, first appears in the cast of Sir Robert Howard's Committee at Drury Lane in 1700 as Teague. *Trench in the Tempest*, the first Grave-digger in *Hamlet* and Marplot in *The Bussybody*, were among his many favourite parts. He is said to have been a friend of Hogarth. He died on the 16th of August 1738.

After his death, John Motley (1692-1750) brought out a book called *Joe Miller's Jests, or Wit's Yule Mummery* (1739), a collection of contemporary and ancient songs and of which a number are told of Miller. Owing to the quality of the jokes in Motley's book, their number increasing with each of the many subsequent editions, any time-worn jest has, somewhat unjustly, come to be called "a Joe Miller."

**Miller, Samuel Freeman (1816-1890),** American jurist, was born in Richmond, Kentucky, on the 5th of April 1816, of Pennsylvania-German stock. He was brought up on a farm, was a clerk in a drug-store, graduated from the medical department of Transylvania University in 1838, and practised medicine in Barbourville, Kentucky, until 1847. In that year he was admitted to the bar, and entered politics as a Whig. His anti-slavery sympathies induced him to settle in Iowa, where in 1850 he freed his slaves and began to practise law in Keokuk, and he soon became a leader of the Republican party in the state. In 1862 he succeeded Justice Peter V. Daniel (1784-1860), as a justice of the U.S. Supreme Court, and served until his death in Washington, D.C., on the 13th of October 1890, when he was senior justice. Miller was a man of great mental force and individuality, and his judgments carried great weight. In 1877 he was a member of the electoral commission, which adopted his proposal for Congress could not "go behind the returns," which was properly accepted by state officials. He was a prominent member of the Unitarian Church and for three years was president of its national conference. He published a volume of *Lectures on the Constitution of the United States* (New York, 1891).

**Miller, William (1782-1849),** leader of the Second Adventists in America, was born on the 5th of February 1782 at Pittsfield, Massachusetts. He was a recruiting officer at the beginning of the War of 1812, and after Plattsburg he was promoted captain, retiring from the army in 1815. About 1816 he settled in Low Hampton, Washington county, New York.
He now joined the Baptist Church at Low Hampton, and, after two years of minute study of the Bible, about 1818 became a Second Adventist. In 1831 he began to lecture, arguing that "two thousand three hundred days" of Daniel viii. 14 meant 2300 years, and that these years began with Ezra's going up to Jerusalem in 457 B.C., and therefore came to an end in 1843, and urging his hearers to make ready for the final coming of Christ in that year. To his many followers, after the year 1843 had passed, he proclaimed that 1844 was the year, that his error was following Hovey instead of Roman chronology, and that the 22nd of October was to be the day. There was renewed excitement among Miller's followers; many of them left their business, and in white muslin robes, on house tops and hills, awaited the epiphany. In spite of disappointment, many still believed with him that the time was near. He returned to Low Hampton and died there on the 20th of December 1849. The Adventists or Millerites, who were formed into a single body in a convention called by him in April 1845, have since separated into several sects: the Evangelical Adventists (1847 in the United States in 1908), who believe in everlasting punishment; the Seventh Day Adventists (64,332), who observe the seventh day, and practise the sacrament of foot-washing; the Advent Christians (26,500), the Churches of God in Jesus Christ (2872), and the Life and Advent Union (3800). Their total number in the United States in 1908 was about 99,300. Miller published in 1853 a pamphlet which was the basis of his lectures; these were published in 1842 as Evidence from Scripture and History of the Second Coming of Christ about the Year 1843.

—See Sylvester Bliss, Memoirs of William Miller (Boston, 1853); James White, Sketches of the Christian Life and Public Labors of William Miller (Battle Creek, 1875); and Edward Eggleston's novel, End of the World (1872).

MILLER, WILLIAM (1795–1861), British soldier, who took a prominent part in the South American Wars of Liberation, entered the British artillery service in 1811, and till 1814 he was continuously on active service with Wellington's army in the Peninsula. In the latter year he accompanied the ill-fated New Orleans expedition. After the general peace he travelled for two years about Europe, and then went to South America. The war which culminated in the expulsion of the Spaniards was just breaking out, and he took command in the Chilean artillery, with which he served during the Chilean part of the war. As a major he commanded the marines on Cochrane's vessel, the "O'Higgins." In 1821 he landed in Peru, to assist General San Martin against the Spanish General Canterac. He was made general of brigade, and became very intimate with Simon Bolivar. He rendered the most conspicuous services at Junin (Aug. 6, 1824), and his regiment, the "Huassers of Junin," covered the retreat. He also took part in the victory of Ayacucho (Dec. 9, 1824). From 1830 to 1839 he filled various high military and political offices in Peru. In the latter year he was involved in the fall of Santa Cruz, and went into exile. For some years he filled the post of British Consul-General of the Pacific Coast. He died on board H.M.S. "Naiad" at Callao, on the 31st of October 1861. See the Memoirs published by his brother John Miller (London, 1827).

MILLER, WILLIAM (1796–1883), Scottish line-engraver, was born in Edinburgh on the 28th of May 1796. After studying in London under George Cook, a pupil of Basire's, he returned to Edinburgh. He executed plates after Thomson of Duddington, Macculloch, D. O. Hill, Sir George Harvey, and other Scottish landscapists, but his chief works were his transcriptions from Turner. The best of these is Clavelly (1824), of The Scottish Coast, a publication undertaken by George Cook and his brother William B. Cook, to which Miller also contributed the Combe Martin and the Portsmouth. He was engaged on the illustrations of England and Wales, 1827–1838; of The Rivers of France, 1833–1835; of Roger's Poems, 1834; and very largely on those of The Prose and Poetical Works of Sir Walter Scott, 1834. In The Provincial Antiquities and Picturesque Scenery of Scotland, 1836, he executed a few excellent plates after Thomson and Turner. Among his larger engravings of Turner's works may be mentioned "The Grand Canal, Venice"; "The Rhine, Osterrey and Feltzen"; "The Bell Rock"; "The Tower of London"; and "The Shepherd." The art of William Miller was warmly appreciated by Turner himself, and Ruskin pronounced him to be on the whole the most successful translator into line of the paintings of the greatest English landscapist. His renderings of complex Turnerian sky-effects are especially delicate and masterly. Towards the end of his life Miller abandoned engraving and occupied his leisure in the production of water-colours, many of which were exhibited in the Royal Scottish Academy, of which he was an honorary member. He resumed the tenebrist, but in 1882 produced two final series of vignettes from drawings by Birket Foster illustrative of Hood's Poems, published by Moxon in 1871. Miller, who was a Quaker, died on the 20th of January 1882.

MILLER, WILLIAM HALLOWES (1801–1880), British mineralogist and crystallographer, was born at Velindre near Llandover, Carmarthenshire, on the 6th of April 1801. He was educated at St John's College, Cambridge, where he graduated in 1826 as fifth wrangler, and became a fellow in 1829. For a few years he was occupied as a college tutor and during this time he published treatises on hydrostatics and hydrodynamics. He also gave special attention to crystallography, and on the resignation of W. Whewell he succeeded in 1832 to the professorship of mineralogy, a post which he occupied until 1876. His chief work, on Crystallography, was published in 1838. He was elected F.R.S. in 1838. In 1852 he edited a new edition of H. J. Brooke's Elementary Introduction to Mineralogy. He assisted in 1843 the committee appointed to superintend the construction of the new Parliamentary standards of weight and height (see Phil. Trans., 1856). He died in Cambridge on the 20th of May 1880.

MILLERAND, ALEXANDRE (1850–1929), French socialist and politician, was born in Paris on the 10th of February 1850. He was educated for the bar, and made his reputation by his defence, in company with Georges Laguere, of Ernest Roche and Duc-Quercy, the instigators of the strike at Decazeville in 1883; he then took Laguerre's place on M. Clemenceau's paper, La Justice. He was elected to the Chamber of Deputies for the department of the Seine in 1885 as a radical socialist. He was associated with M.M. Clemenceau and Camille Pellatet as an arbitrator in the Carmaux strike (1892). He had long had the ear of the Chamber in matters of social legislation, and after the Panama scandals had discredited so many politicians his influence grew. He was chief of the Socialist left, which then mustered sixty members, and edited until 1896 their organ in the press, La Petite République. His programme included the collective ownership of the means of production and the international association of labour, but when in June 1899 he entered Waldeck-Rousseau's cabinet of "republican defence" as minister of commerce he applied himself to practical reform, to the improvement of the mercantile marine, to the development of trade, of technical education, of the postal system, and to the amelioration of the conditions of labour. Labour questions were entrusted to a separate department, the Direction du Travail, and the pension and insurance office was also raised to the status of a "direction." The introduction of trades-union representatives on the Supreme Labour Council, the organization of local labour councils, and the instructions to factory inspectors to put themselves in communication with the councils of the trades-unions, were measures intended to secure the rigorous application of earlier laws devised for the protection of the working-classes. His name was especially associated with a project for the establishment of old age pensions, which became law in 1905. He became in 1898 editor of La Lanterne. His influence with the extreme Socialists had already declined, for it was said that his departure from the true Marxist tradition had disintegrated the party.

For his administration in the Waldeck-Rousseau cabinet see A. Lavy, L'Éclair de la Millénaire (1902); his speeches between 1899 and 1907 were published in 1907 as Travail et travailleurs.

MILLERITE, a mineral consisting of nickel sulphide, NiS. Crystals belong to the rhombohedral system and have the form
of slender needles arranged in divergent groups or of delicate fibres loosely matted together. The colour is brass-yellow and the lustre metallic. Before the chemical composition of the mineral had been other place it had been known as "hair pyrites" or "hair pyrites" (Ger., Haarkies), and was not distinguished from the capillary forms of pyrites and marcasite: the name millerite was given by W. Haidinger in 1845, in honour of W. H. Miller. The hardness is 3-3½ and the specific gravity 5-65. There are perfect cleavages parallel to the faces of the rhombohedron (100); and gliding planes parallel to the faces of the rhombohedron (110), on which secondary twinning may be readily produced artificially by pressure.

Typical specimens of millerite are found in the coal measures in the neighbourhood of Merthyr Tydfil in South Wales, where the delicate needles and fibres occur with crystals of quartz and pearl-spar in the fissures of septarian nodules of clay-ironstone. Radiating groups of needles are found with ankerite in cavities in haematite in the Sterling mine at Antwerp in Jefferson county, New York. At the Gap mine in Lancaster county, Pennsylvania, the mineral occurs as fibrous encrusting masses with a velvety lustre. The most perfect crystals are those formerly found with calcite, diopside and a bright green chrome-garnet in a nickel mine at Orford in Sherbrooke county, Quebec.

**MILLER'S THUMB** (Cottus gobio), a small fish, abundant in all rivers and lakes of northern and central Europe with clear water and gravelly bottom. The genus *Cottus*, to which the miller's thumb belongs, is easily recognized by its broad, flat head, rounded and scaleless body, large pectoral and narrow ventral fins, with two dorsal fins, the anterior shorter than the posterior; the preoperculum is armed with a simple or branched spine. The species of the genus *Cottus* are rather numerous, and are confined to the north temperate zone of the globe, the majority being marine, and known by the name of "bullhead." The miller's thumb is confined to fresh water; and only one other freshwater species is found in Europe, *C. pocillopus*, from rivers of Hungary, Galicia, and the Pyrenees; some others occur in the fresh waters of northern Asia and North America. The miller's thumb is common in all suitable localities in Great Britain, but is extremely rare in Ireland; in the Alps it reaches to an altitude exceeding 7000 ft. Its usual length is from 3 to 5 in. Generally hidden under a stone or in a hollow of the bank, it watches for its prey, which consists of small aquatic animals, and darts when disturbed at an ordinary rapidity to some distance. The female deposits her ova in a cavity under a stone, whilst the male watches and defends them until the young are hatched and able to shift for themselves.

**MILLET, FRANCIS DAVIS** (1846–1897), American artist, was born at Mattapoisett, Massachusetts, on the 3rd of November 1846. He was a drummer boy with the Union forces in the Civil War; graduated from Harvard College in 1869; and in 1871 entered the Royal Academy of Fine Arts, Antwerp, where he studied under Van Lerius and De Keyser. In 1873 he was made secretary of the Massachusetts commission to the Vienna Exposition. During the Russo-Turkish War of 1877–78 he was correspondent of the London *Daily News and Graphic*, and of the *New York Herald*. On his return he was made a member from the United States of the International Art Jury at the Paris Exposition of 1878. He was director of decorations at the Columbian Exposition, Chicago, 1893, and in 1898 he went to Manila as war correspondent for *The Times* and for *Harper's Weekly*. In 1888 he became a member of the Society of American Artists, and in 1889 was elected to full membership in the National Academy of Design, New York, and in 1890 made one term its vice-president; he became a member also of the American Water Color Society and of the Institute of Painters in Oil Colours, London. As a decorative artist his work may be seen at Trinity Church, Boston; the Bank of Pittsburgh; and the Capitol at St Paul, Minnesota. His pictures are in many public collections: among them are "A Cosy Corner," in the Metropolitan Museum of Art, New York; "At the Inn," in the Union League Club, New York; and "Between Two Fires," in the Tate Gallery, London. He also wrote essays and short stories, and an English version of Tolstoi's *Sebastopol* (1882); and among his publications are *The Danebye* (1851), *Capillary Crime and other Stories* (1892), and *Expedition to the Philippines* (1899).

**MILLET** (or Milé), JEAN FRANÇOIS (c. 1642–1679), commonly called FRANCISQUE, was born at Antwerp about 1642, and is generally considered amongst the painters of Flanders on account of the accident of his birth. But his father was a Frenchman, a turner in ivory of Dijon, who took service with the prince of Condé and probably returned after a time to his native country. He remained long enough in Antwerp to apprentice his son to an obscure member of a painter family called Laurent, pupil of Gabriel Franck. With Laurent, Francisque left Antwerp for Paris, and there settled in 1660 after marrying his master's daughter. He was received a member of the Academy of Painting at Paris in 1673, and after gaining consideration as an imitator of the Poussins he died in 1679, bequeathing his art and some of his talents to one of his sons. Francisque probably knew, as well as imitated, Nicolas Poussin, Gaspar Duget and Sebastian Bourdon; and it is doubtful because of his assistance with these traveller artists. That, being himself without familiarity with the classic landscapes of Greece, he was able to imagine and reproduce Italian and Arcadian scenery with considerable grace and effectiveness. It is indeed surprising to observe, even at this day how skillfully he executed these imaginary subjects, enlivened them with appropriate figures, and shed over them the glow of a warm yet fresh and sparkling tone. Twelve of his most important landscapes, which remained in the palace of the Tuileries, were destroyed by fire; and though many of his pieces may still be found catalogued in Continental and English collections, others in his own he was given to distrusting his work. His son JEAN FRANÇOIS MILLET, the younger (1666–1732), also called Francisque, was born in Paris, and was made a member of the Academy of Painting in 1700. He is not quite so independent in his art as his father; but he had clever friends, and when he wanted figures to his landscapes, he consulted Watteau, and other followers of the "court shepherdess" school. In the museum of Grenoble is a "Paysage" by him which is prettily adorned with Watteau's figures.

**MILLET, JEAN FRANÇOIS** (1814–1875), French painter, who came of a peasant family, was born on the 4th of October 1814 in the hamlet of Gruchy, near Gréville (Haute-Marne), in the wild and picturesque district called La Hague. His boyhood was passed working in his father's fields, but the sight of the engravings in an old illustrated Bible set him drawing, and thenceforward, whilst the others slept, the daily hour of rest was spent by Millet in trying to render the familiar scenes around him. From the village priest the lad learnt to read the Bible and Virgil in Latin, and acquired an interest in one or two other works of a high class which accompanied him through life; he did not, however, attract attention so much by his acquisitions as by the stamp of his mind. The whole family seems, indeed, to have had a character of industry and dignity, and when Millet's father finally decided to test the vocation of his son as an artist, it was with a gravity and authority which recalls the patriarchal households of Calvinist France. Two drawings were prepared and placed before a painter at Cherbourg named Mouchel, who at once recognized the boy's gifts, and accepted him as a pupil; but shortly after (1835) Millet's father died, and the eldest son, with heroic devotion, took his place at home, nor did he return to his work until the pressing calls from without were solemnly enforced by the wishes of his own family. He accordingly went back to Cherbourg, but after a short time spent there with another master (Langlois) started with many misgivings for Paris. The council-general of the department had granted him a sum of 600 francs, and the town council promised an annual pension of 400, but in spite of friendly help and introductions Millet went through great difficulties. The system of the École des Beaux Arts
MILLET

467

was at home, and it was not until after much hesitation that he decided to enter an official studio—that of Delaroc.
The master was certainly puzzled by his pupil; he saw his ability, and, when Millet in his poverty could not longer pay the monthly fees, arranged for his free admission to the studio, but he tried in vain to make him take the approved direction, and lessons ended with " Eh, bien, allez à votre guise, vous êtes si nouveau pour moi que je ne veux rien vous dire." At last, when the competition for the Grand Prix came on, Delaroc gave Millet to understand that he intended to secure the nomination of another, and thereupon Millet withdrew himself, and with his father planned to live in a little studio in the Rue de l'Est. He had renounced the beaten track, but he continued to study hard whilst he sought to procure bread by painting portraits at 10 or 15 francs apiece and producing small "pastiches" of Watteau and Boucher. In 1850 Millet went back to Gréville, where he painted "Sailors Mending a Sail" and a few other pictures—reminiscences of Cherbourg life.

His first success was obtained in 1854, when his "Milkwoman" and "Lesson in Riding" (pasted) attracted notice at the Salon, and friendly artists presented themselves at his lodgings only to be sent away. A village on the skirts of Fontainebleau then disappeared. Millet was at Cherbourg; there he remained, but having amassed a few hundred francs he went back to Paris and presented his "St Jerome" at the Salon of 1855. This picture was rejected and exists no longer, for Millet, short of canvas, painted it over "Oedipus Unbound," a work which during the following year was the object of violent criticism. He was, however, no longer alone; Diaz, Eugène Tourneux, Rousseau, and other men of note supported him by their confidence and friendship, and he had by his side the brave Catherine Lemaire, his second wife, a woman who bore poverty with dignity and gave courage to her husband through the cruel trials in which he penetrated by a terrible personal experience the bitter secrets of the very poor. To this date belong Millet's "Golden Age," "Bird Nesters," "Young Girl and Lamb," and "Bathers"; but to the "Bathers" (Louvre) succeeded "The Mother Asking Alms," "The Workman's Monday," and "The Winnowers." This last work, exhibited in 1858, obtained conspicuous success, but did not sell till Lédrac Rollin, informed of the painter's dire distress, gave him 500 francs for it, and accompanied the purchase with a commission, the money for which enabled Millet to leave Paris for Barbizon, a village on the skirts of the forest of Fontainebleau. There he settled in a three-roomed cottage for the rest of his life—twenty-seven years, in which he wrought out the perfect story of that peasant life of which he alone has given a "complete impression." Jules Breton has coloured the days of toil with sentiment; others, like Courbet, whose eccentric "Funeral at Ornans" attracted more notice at the Salon of 1856 than Millet's "Sowers and Binders," have treated similar subjects as a vehicle for protest against social misery; Millet alone, a peasant and a miserable one himself, saw truth, neither softening nor exaggerating what he saw. In a curious letter written to Senier at this date (1850) Millet expressed his resolve to break once and for all with mythological and undraped subjects, and the names of the principal works painted subsequently will show how steadfastly this resolution was kept. In 1852 he produced "Girls Sewing," "Man Spreading Manure"; 1853, "The Reapers"; 1854, "Church at Gréville"; 1855—"the year of the International Exhibition," at which he received a medal of first class—"Peasant Grafting a Tree"; 1857, "The Gleaners"; 1859, "The Angelus," "The Woodcutter and Death"; 1860, "Sheep Shearing"; 1861, "Woman Shearing Sheep," "Woman Feeding Chickens"; 1862, "Beet-Planters"; 1863, "Man with Hoe," "Woman Carding"; 1864, "Shepherds and Flock, Peasants Bringing Home a Calf Born in the Fields"; 1865, "Knitting Lesson"; 1870, "Buttermaking"; 1871, "November—Recollection of Gruchy." Any one of these works will show how great an influence Millet's previous practice in the nude had upon his style. The dresses worn by his figures are not clothes, but drapery through which the forms and movements of the body are strongly felt, and

their contour shows a grand breadth of line which strikes the eye at once. Something of the imposing unity of his work was also, no doubt, due to an extraordinary power of memory, which enabled Millet to paint (like Horace Vernet) without a model; he could recall with precision the smallest details of attitudes or gestures which he proposed to represent. Thus he could count on presenting free from afterthoughts the vivid impressions which he had first received, and Millet's nature was such that the impressions which he received were always of a serious and often of a noble order, to which the character of his execution responded so perfectly that even a "Washerwoman in her Pub" will show the grand action of a Meden. The drawing of this subject is reproduced in Souvenirs de Barbizon, a pamphlet in which M. Piédagnel has recorded a visit paid to Millet in 1864. His circumstances were then less evil, after struggles as severe as those endured in Paris. A contract by which he bound himself in 1860 to give up all his work for three years had placed him in possession of 1000 francs a month. His fame extended, and at the exhibition of 1867 he received a medal of the first class, and the ribbon of the Legion of Honour, but he was at the same moment deeply shaken by the death of his faithful German, in whom he rallied from a time he never completely recovered his health, and on the 20th of January 1875 he died. He was buried by his friend's side in the churchyard of Chailly. His pictures, like those of the rest of the Barbizon school, have since greatly increased in value.

See the article Barbizon; also A. Sensier, Vie et œuvre de J. F. Millet (1874); Piédagnel, Souvenirs de Barbizon, &c. (1876); D. C. Thomson, The Barbizon School (1894); Richard Muther, J. F. Millet (1905); Genèse, Millet et Rousseau (1902). (E. F. S. D.)

MILLET (Fr. millet; Ital. miglietto, diminutive of miglio = L. mille, a thousand, in allusion to its fertility), a native of eastern Asia is one of the most wholesome and palatable Indian cereals. It is annual, grows 4 to 5 ft. high, and requires dry light soil. German Millet (Ger. Kotlenhöhe, Mohar) is probably merely a less valuable and dwarf variety of S. italica, having an erect, compact, and shorter spike. The grains of both are very small, only one half as long as those of common millet, but are exceedingly prolific. Many stalks arise from a single root, and a single spike often yields 2 oz. of grain, the total yield often reaches five times the weight of wheat. They are imported for poultry feeding like the former species and for cage-birds, but are extensively used in soups, &c., on the Continent. Numerous other species belonging to the vast genus Panicum—the largest among grasses, of which the following are among the most important—are also cultivated in tropical or subtropical countries for their grain or as fodder

Sectoria italica.
MILLIGAN—MILLIPede

CLASS DIPLOPODA.

Structure.—The anterior extremity is provided with a distinct head which by its general form and the nature of its appendages is as sharply marked off from the body as is the case in the Hexapoda. It always bears at least three pairs of appendages, the eyes when present being median in position on the Proct corpse a peculiar sense organ.

The inferior edge of the head plate overhangs the mouth and is termed the hypostoma. The exoskeleton of a typical somite consists of the following elements: a dorsal plate, a ventral plate, and a pleural plate on each side. To the external margin of the ventral plate or sternum is articulated a pair of legs and between the leg and the pleural plate is situated the spiracle of the tracheal system. But the segmentation of the Diplopoda presents two marked peculiarities. The first is the fact that, with the exception of a few of the anterior leg-bearing segments and perhaps one or two of those at the posterior end of the body, a single dorsal plate or tergum is present, its pleural plates overlying two sternal plates, two pairs of legs and two pairs of spiracles. Hence these segments appear to be double and to be furnished with twice as many legs as is normal in the Arthropoda—a peculiarity which has suggested the term "Diplopod" or "double-footed" for this group. In general it is believed that each tergal plate results from the coalescence of two originally distinct adjoining segments; but the same effect would be produced by the enlargement of one of a pair of terga and the complete exfoliation of the other. It is in favour of the latter view that there is only a single pair, and not two pairs, of stink-glands on each so-called double tergal plate. Unfortunately the history of the development of the segments does not clear up the difficulty since the terga of the double segments are single from the first, and no evidence either of fusion or excision is supplied. The second peculiarity is the great development of the tergal sclerite as compared with the sternal. Only very rarely (i.e. in Platydnesmus) is there a broad sternal plate. In the majority of cases the lateral edges of the tergum are bent downwards andwards towards the mid ventral plate; the sterna at the same time is so much reduced that the basal segments of the legs of opposite sides are almost in contact. The pleural plate on each side usually disappears either by suppression or by fusion with the tergum. The sterna with their attached legs often remain free. But quite commonly the coalescence of the skeletal elements is carried to such an extreme that each segment is just a solid ring with two pairs of movable appendages. The last segment is differently constructed from the others. It is always limbless, and usually consists of a complete tergal ring, a single sternal plate, and a pair of movable anal valves which are normally closed, but are capable of being opened for the passage of faeces. These anal valves are possibly the homologues of the plural scutes of a normal segment. The appendages are modified.
as a single pair of antennae, two or three pairs of jaws and a variable number of walking-legs, of which one or more pairs may be transformed into gonopods. The antennae are short and very similar to the legs. They are preoral in position and are formed of seven segments, the seventh or distal segment being small, as a rule, and furnished with a sense organ which is probably olfactory or tactile in function. The first pair of jaws or the mandibles of the first pair are the most anterior of the postoral appendages. They are large, powerful, and usually consist of three or two segments, a basal or

on each side a large branching nerve to other organs in the segment. In the Opisthosphorm ph (Julus, Spirostreptus) and the Onisco-morpha (Glomeris, Sphaerotherium) the ganglia are spaced at equal distances on the cord, but in the Merochaeota (Polydesmus) they are grouped in pairs to correspond to the spacing of the legs. The apodous penultimate and anal segments are innervated from the last ganglion of the cord, as are also the gonopods of the males of

FIG. 3.—Inner view of ventral area of a single segment of *Julus*, much enlarged to show the structure and arrangement of the tracheal organs. The two pairs of tracheae are seen in situ, the posterior pair overlapping the anterior.

**h**. Posterior margin of the body—Fine tracheae given off from it, as venous.(term). **ms**. Respiratory muscle attached to tracheal sac. 

**sI**. Tubular chamber of tracheae. **m**. Ventral body muscle.

cardio, which is sometimes absent, a second or stipes, and a third or mala, the latter being supplied with a strong tooth and pectinate lamellae. In all Diplopoda, with the exception of the Psclapoguathrae there are only two pairs of jaws, those of the second pair forming a large plate, the gnathochiliarium, which acts as a lower lip. It consists of several distinct sclerites, two external on each side, the proximal known as the carido, the distal as the stipes, the latter being tipped with one or two lobes (malae) and far exceeding the carido in size. Between the external plates there is a median proximal plate (mentum) generally of large size and often itself subdivided, and a pair of distal plates (lingue). Behind the base of the gnathochiliarium there is a single large transverse plate, the hypostoma. In the Psclapoguathra, the jaws representing the gnathochiliarium are differently constructed and an additional pair, the maxillulae, has been recently detected between the gnathochiliarium and the mandibles. Behind the gnathochiliarium, which from embryological data appears to result from the modification of a single pair of appendages, a legless somite has been detected in some embryos. Possibly the plate referred to above as the hypostoma is its sternal element.

The heart is a median dorsal vessel composed of a series of chambers each giving off a pair of arteries and furnished with a pair of orifices or ostia. According to Newport, the anterior chamber lying in the second segment is prolonged into an aortic trunk from which arise three pairs of lateral arteries dipping down on each side of the alimentary canal and uniting beneath it in a common ventral vessel. The heart is enveloped in a delicate pericardial membrane and is supported by lateral alary muscles. The alimentary canal is a simple tube extending usually straight throughout the body from mouth to anus. Only in the Onisco-morpha is it looped, thus suggesting the origin of this short-bodied group of millipedes from longer, more vermiform ancestors. A pair of so-called salivary glands opens into the fore-gut near its anterior extremity and one or two pairs of malpighian tubes communicate with the hind-gut at its junction with the broad mesenteric portion of the canal. Respiration is effected by means of tracheal tubes which open internally with the exterior by means of a series of orifices just above the bases of the walking limbs. Each spiracle leads into a longer or a shorter pouch whence the tracheae, which are of two kinds, arise. In the majority of the orders the tracheae are tufted, that is to say, they form two bundles of short simple tubes springing from the innermost corners of each pouch. In the Onisco-morpha, however, each pouch gives rise to a number of long tubes which extend through the body and somewhat resemble those of the Chilopoda except that they neither branch nor are extensive. As in the Chilopoda and Hexapoda the tracheae are strengthened and kept expanded by a slender spiral filament.

The central nervous cord consists of two strands so closely approximated as to be practically fused, with a small ganglionic enlargement for each pair of legs. Hence in the double segments there are two such ganglia, which in addition to the cranial nerve give off

**Fig. 4.—Diagram of the nervous and circulatory system of *Sphaerotherium obtusum*, a South African species of Onisco-morpha.**

**gs** and **gl**. Second and twenty-second ganglia of chain, the posterior nerve of each ganglion, **ngn**. Supplies the leg, **tr**. internal or proximal ends of which are continuous with the fibres of the optic nerve. The optic lobes are large and extend almost the entire length of the body beneath the alimentary canal. The oviducts are sometimes separate tubes (Lysiotopetaform, sometimes confluent and divided just before terminating in the two orifices of the legs of the second pair (Julus). The testes and seminal ducts occupy the same position and extent as the ovary and oviducts. The ducts are sometimes coiled, sometimes divided, sometimes united by transverse ridges across the middle line, and are sometimes branched posteriorly. They bear short cecal diverticula in which the semen is developed. There are no accessory glands associated with the reproductive organs; but in some species of Polyxenus, there is a pair of receptacula seminis extending backwards alongside the ovary and opening into the oviduct.

**Fig. 5.—Gonopods of Trigoniulus andersoni, one of the Opisthospermophora (Spirobolidae).**

A. Anterior view, and B, lateral views of the apparatus. ant. anterior, and post. posterior portions of the coleopod eneasheathing the phallopod, of which the proximal portion, ph. is shown.

C. Phallopod removed from the coleopod.

The secondary sexual characters of the males are of great taxonomic importance. The seminal ducts, like the oviducts, open behind the legs of the second pair. Associated with them in the Limacomorpha (Gomieridiasmus), there is a pair of very long retractile penes. In the Spirostreptoids, and Julidae the penes are much shorter and have coalesced. Sometimes they are undeveloped (Spirobolidae). In other cases, the Meroschacta, Oniscomorpha, etc., the ducts transverse the coxae of the legs of the second pair. But in all these groups, with the exception of the Oniscomorpha, semen is transferred from the genital orifices, with or without the aid of the penes, either into the first or second pairs of appendages of the seventh segment which are modified in various ways, and are termed phallopods. When the posterior legs are so modified the anterior are as a rule more profoundly altered to form a protective sheath, or coleopod, for the phallopod; and as a further precaution the entire apparatus is usually withdrawn within the seventh segment. In the Oniscomorpha the semen is transferred into a pair of receptacles developed upon the coxae of the legs of the last pair, which are chelate and are termed gonopods. The male appendages that are modified in the above described ways are comprehensively spoken of as gonopods. Other secondary sexual characters, like the striolating organs of the males of some Oniscomorpha, the second pair of legs of some Spirostreptoids, the third pair of legs of some Julidae, the first posterior pair of legs, the ninth abdominal segment, etc., are modified to open upon the genital area, or upon the lateral side of the thorax, as annals or stigmatic organs. The most important glands in the Diplopoda are the reproductive or stink-glands, which, except in the Oniscomorpha, Limacomorpha and Ascopermophora, open by pores upon the sides of more or fewer of the segments. They secrete a fluid with an unpleasant odour, breaking up in one case into cyanide of potassium, and are practically the only means of protection, apart from the hard exoskeleton, which Diplopoda possess. In some monotypic genera the glands also exist and open upon papilla upon the posterior border of the last tergal plate. They are found in the Ascospermophora, Stemmulidae and Prorhaterasphephora, and are used for spinning nests for the eggs and protective cases for the young during exuviation.

**Classification.**—The existing members of the class Diplopoda may be classified as follows:

**Subclass Pselaphognathia.**

Order: Pnicellula (Polyxenus).

Order: Oniscomorpha (Gomeridiasmus, Zonobion).

Limacomorpha (Gomeridiasmus).

Colobogonha (Polyzoon, Siphonophora).

Ascospermophora (Charadoma).

Prorhaterasphephora (Lytophelium).

Merochacta (Polyxenus).

Opisthospermophora.

Suborder: Stemmulidae (Stemmius).

Spirobolidae (Spirobolus).

Spirostreptoids (Spirostreptus).

Julidae (Julus, Nemasona).

**Fig. 6.—Jaws of Polyxenus lagurus.**

A. Jaws of second and third maxillula; mx. A, branchiform branch of maxilla; mx. B, lobate process of maxilla; mx. ext., external plate of maxilla perhaps corresponding to the stipes of the gnathochilarium of the Chilognatha; mx. int., internal plate of maxilla, perhaps corresponding to the mentum and pronotum of the gnathochilarium (by Carpenter mx. int. is regarded as an appendage posterior to the maxilla); mb, membrane.

B, Mandibles of Polyxenus lagurus.

Order: Chilognatha (Ancylochilus).

Head large, usually with lateral eyes. Antennae eight-jointed, attached near the middle of the front of the head. On the dorsal side of the body there are eleven segments, simple and compound. The first four of these bear one pair of legs each, the succeeding four two pairs of legs, the ninth segment one pair, making a total of thirteen pairs of legs. The tenth and eleventh or anal segment are legless. There is a narrow, external area separating the bases of the legs of the two sides. There are no reproductive glands. In the male none of the legs are modified as gonopods, but the coxa of each of the legs of the second pair is furnished with a conical penis, which during copulation, it may be supposed, is inserted into the genital orifice of the female, which occupies a corresponding position in that sex. The young when first hatched has only three pairs of legs and five segments. The millipedes of this order are all of small size, measuring at most only a few millimetres in length. The best-known genera are Polyxenus and Lophoprotus, both of which occur in Europe. Other forms have been discovered in the West Indies, North and South America, and Ceylon; and it is probable that the group is much more cosmopolitan in range. They live under stones or the loosened bark of trees. The carboniferous fossil, Palaeoecampa, is usually referred to the sub-order Polyxenidae.

**Fig. 7.—Ventral view of Polyxenus lagurus much enlarged, actual length a little over 4½th of an inch.**

A, Position of generative openings.
Mandibles, two- or three-jointed; maxillae absent, the jaws of the second pair being represented by the gnathochilium described above.

Order Oniscomorpha.

Body short and broad, hemispherical in transverse section; convex above, flat below, and capable of being spherically coiled. The exoskeleton is typical of a millipede, a pair of free pleural sclerites, two pairs of small tracheal sclerites and two pairs of legs, the latter attached to the ventral membrane, which has no sternal plates. The tergal plates are twelve or thirteen in number, whereas the first is very small, the second enormously expanded laterally, and the last, also enlarged and probably representing at least three segments, extends laterally and posteriorly like a hood over the posterior end of the body without forming a chitinous ring round the anal valves and sternum. In the male the legs of the penultimate pair are sometimes modified as claspers; those of the last pair are always enlarged and prehensile, and bear on their coalesced basal segments a pair of sperm-carrying processes analogous to the phallopods of other groups. Apart from these organs the male has no penis, the seminal ducts perforating the coxae of the legs of the second pair. This order contains two well-marked suborders, the Glomeroida and the Zephronoida. The Glomeroida, comprising the families Glomeridae, Gerasenidae, Onomerdia, have the antennae approximated on the head, the eyes uniserial and twelve (rarely eleven) tergal plates. To this group belong the common pill-millipedes of Europe and North Africa. In North America the Onomerdia alone are found. The Zephyrionidae, with the single family Zephyrionidae, have the antennae at the sides of the head, the eyes composed of a spherical cluster of ocelli, and always thirteen tergal plates. This group is common in the tropical and southern continents of the Old World, having representative genera in South Africa, Madagascar, India, Malaysia, Australia and New Zealand. They are much larger forms than the Glomeroida, large specimens reaching two or three inches in length. In addition to the characters mentioned above the Zephyrionidae differ from all other Diplopoda in having long tubular tracheae and the alimentary canal bent upon itself.

Order Limacomorpha.

Resembling the Oniscomorpha in the shape and structure of a typical segment, except that the tracheal plates are unrepresented; in the facts that the last tergal plate does not form a complete ring round the anal area, and that the last pair of legs in the male are modified; but differing from them in that the body consists of nineteen or twenty segments, is elongate, and tapers anteriorly and posteriorly, the second and last tergal plates being small; in the presence in the male of a pair of long hairy protrusible penes between the legs of the second and third pairs, and in the structure of the gonopods, which, instead of being chelate, terminate in a slender, tapering tarsal segment. This order contains two families: Zephyronidomidae (Zephyronidomidae) and Glomeridomidae (Glomeridomidae), the former from tropical Asia, the latter from tropical America. The largest of these millipedes reach a length of only about 7 mm. Nothing special is known of their habits.

Order Colobognatha.

Body elongate, capable of being spirally coiled, consisting of a large and indefinite number of segments, each being furnished with a distinct often large sternal area, and with the pleural sclerite or membrane distinct from the tergum. The last tergal plate forms a complete ring round the anal valves. Legs with coxal pouches; those of the seventh segment transformed into gonopods of a very simple type in the male, which is also furnished with a double penis completely or partially confluent with the coxae of the legs of the second pair. Head always small, frequently triangular or piriform, in the latter case the gnathites reduced in size and complexity. Repugnatorial pores present and lateral. The genera of this order are divisible into three families: the Plateodesmidae (Plateodesmus, Pseudodesmus), Polyzoididae (Polyzoon, Siphonites), Siphonophoridae (Siphonophora). Of these the Plateodesmidae have described least and the Siphonophoridae most from the typical Diplopod in the structure of the mouth parts. The group is for the most part tropical, one genus only, Polyzoon, extending as far north as Central Europe.

Order Ascospermophora.

Body elongate, consisting of from twenty-six to thirty-two segments, but not varying within specific limits; the pleurae coalesced with the terga, the sterna free. More or fewer of the anterior ten pairs of legs may be modified in the males, but no true phallopods are differentiated, the function of seminal receptacles being performed (according to C. Verhoef) by the extricite coxal pouches of the two pairs of legs of the eighth segment. The seminal ducts in the male perforate the coxae of the seventh segment. There are no repugnatorial pores, and the terga are furnished with three pairs of symmetrically placed hairs or bristles. On the posterior border of the last tergal plate there is a pair of spinning papillae. The millipedes of this order, also called Coelobocchae, are referable to several families: Choreodeidae (Choreodesmus), Craspedosomidae (Craspedosoma), Heterochoreosomidae (Heterochoreosoma), &c. The Heterochoreosomidae belong to the Oriental region, extending from India to New Zealand. The others are particularly abundant in genera and species in North and Central America and Europe; but are unknown in Africa, south of the Sahara.

Order Proterospermophora.

Differing from the Ascospermophora in that the number of segments is large and variable; they are furnished with repugnatorial pores, and with the three pairs of setae. In the males the anterior appendages of the seventh segment are modified as phallo- pods, and the seminal ducts perforate the coxae of the legs of the second pair.

This order, containing the family Lysiopetalidae (Lysiopetalum), is widely distributed in Europe and North America. Large examples of some of the species, e.g. L. zanthinum, reach a length of 4 or 5 ins.

Order Merobochaeta.

Resembling the Proterospermophora in having only the anterior appendages of the seventh segment converted into phallopods and the seminal ducts perforating the coxae of the second legs in the males; but differing essentially in that the sternum is...
solidly welded to the rest of the exoskeleton of the segments, which are either fourteen or twenty in number, in the absence of eyes and of spinning papilae, and in having six-jointed legs. This order is homogeneous, and the distribution of a very large number of genera by which some authors are referred to the single family Polydesmidae. We shall, therefore, make no attempt to separate it into subfamilies. Many species are brightly coloured, and some individuals of the Oriental genus Nemasoma, which is remarkable for having the sterna nearly distinct and tipped with the ventral surface of the anterior ends of their bodies opposed, the male holding the female securely by the head while the extended phallopods carrying the semen are brought into contact with her genital orifice. In the Polydesmidae pairing is effected in the same way except that the male and female instead of intercoiling remain extended, the male clasping the female with his legs. In the Oniscoidea the sexes also pair to front, not head to head, however, and the genital opening in the anal segment of the male can be applied to the second pair of postoral appendages in the female. Some males of this group, e.g., Phaerothorax, have in the possession organs of their posterior gonopods and stridulate when finding the females.

The method of disposing of the young, which usually have only three pairs of legs at hatching, differs in various groups. In Julus and Archispirostreptus the young hatches from the egg within the female, and she bears the young in her possession; in Asaphids and Polydesmids, the young escape immediately after hatching, and the mother may be said to be the sole care-giver.

Order Opisthospermoidea. Resembling the Proterospermoidea in possessing a large and variable number of segments, both sexes, with the exception of the last and the anterior four or five, is furnished with a pair of repugnatorial pores, but differing essentially from them in that the posterior pair of appendages of each sex is a single penis, or penis-pair, and in that the segments except the last two, the four first and the seventh; the latter, since the figured specimen was a male, has the anterior leg converted into a phallopod which is concealed beneath the body.

The presence of the segments is usually provided with lateral lamellae or tuberculate expansions bearing the repugnatorial pores, which are only very rarely absent.

From Balfour, after Metschikoff.

MILLIPEDE

are questions to which no answer can as yet be given. Judging from the segmentation and the appendages the body is composed of twelve somites, including the last or anal, which, like the penultimate somite, is limbless. Each somite in front of the penultimate

usually six in number, excluding that of the anal segment; each of the anterior five of these overlies two limb-bearing somites, the first covering the somite of the rudimentary limbs and of the first pair of locomotor legs, the second those of the second and third pairs of locomotor legs, and so on. This condition is an admixture of the far complexer fusion of somites seen in the Diplodota. The sixth tergal plate belongs to the limbless penultimate somite. The duplex character of the first five terga is suggested in Pauropus by the presence of two rows of sensory bristles; there being only one such row upon the sixth tergum. In the aberrant genus Brachypauropus the evidence is practically completed by the correspondence in number between the terga and pairs of legs, there being a divisional line between the two rows of setae. On each side of the body there are five long pustulate tactile setae situated on the second to the sixth terga in Pauropus, and on the pleural area corresponding to these terga in Brachypauropus.

The cerebral mass of the nervous system is large and when viewed from above is seen to consist of two lobes defined by a median groove. In the absence of eyes no optic nerves are found; there are two antennal lobes whence arise, close together, the antennal nerves. Two short commissural cords connect the cerebral mass with the subepithelial ganglion, a composite mass formed of the nervous centres which supply the two pairs of jaws and the rudimentary legs of the first pair. Behind this large ganglion the cord, which shows superficially no trace of its double origin, presents a ganglionic swelling for each pair of legs. No circulatory or respiratory organs have been detected.

The alimentary canal consists of a short, narrow fore-gut, a large, straight mid-gut, and a moderately long hind-gut which is itself composed of two parts, an anterior narrow tube which opens into a dilated, piform, posterior portion, narrowing gradually to terminate in the anus. Opening into the anterior extremity of the fore-gut there is a pair of "salivary" glands. Malpighian tubes have been found in some forms, i.e. females of Eurypauropus spinosus, but not in any examples, male or female, of Pauropus huxleyi. Where present they open at the point of union of the mid-

E. Antenna of Eurypauropus spinosus; fl, flagella; gl, sensory organ.

Fig. 13.—Enlarged view of Pauropus huxleyi, from ventral side. A pair of bud-like processes. The first and last pairs of ambulatory limbs consist of five segments; in the remaining pairs the terminal segment may be subdivided into two, so that there may be six segments in all. The ambulatory limbs are usually terminated by three claws, a principal and two subsidiary, each claw being accompanied by a membranous pad. Between these limbs, which are relatively longer and stronger than in the Diplodota and evenly spaced on each side of the body, extends a soft-skinned sternal area. The distensible pleural region of the body is also membranous, but the dorsal area is covered by chitinous plates or terga.

After Lubbock.

Fig. 14.—Pauropoda.

A. Alimentary canal of Pauropus; fg, fore-gut; sg, salivary gland; mg, mid-gut; hg, anterior portion of hind-gut; a, anus; m.pl., malpighian tubule.
B. Female genital organs of Eurypauropus; ov, ovary; ovd, oviduct; rs, receptaculum seminis; go, genital orifice.
C. Male genital organs of Pauropus; p and bg, anterior and posterior portions of testes; tds, ts, vas deferens; rs, vesicula seminalis; cd, common duct; go, genital orifice.
and hind-guts. The generative organs in the female are very simple, and resemble those of the Diplopoda. In the male they are highly complex, and unlike those of any known Arthropod in certain particulars. The wide, unpaired ovary extends nearly to the posterior end of the body, and passes throughout its length. The posterior portion of the duct is wide. The anterior, an abruptly narrowed tube, curves round the nerve-cord and opens by a single sub-median orifice in the third anterior pair of segmental openings opposite the short duct of a spherical receptaculum seminis. In the male the testis is never paired. Sometimes it is single, sometimes divided into an anterior and a posterior mass, and sometimes may be as many as three smaller ducts which soon expand into wider tubes. These tubes, regarded as seminal vessels, after forming a complex of loops, coils and cecal prolongations, ultimately unite beneath the intestine in a single tube which passing forwards divides on each side of the alimentary canal to terminate in the two penes situated just behind the bases of the second pair of complete legs, that is to say, the legs of the third segment. At the root of the penis there is an accessory gland on the duct, and a little farther back a much larger glandular swelling.

The Pauropoda are divided into three rather sharply defined groups. These may be briefly characterized as follows.

(Pauropus, Pauropodina.)

Head not covered by the first tergal plate. Anal segment not covered by the sixth tergal plate. Terga of the first ten segments fuses in couples. Tactile setae situated on the lateral line of the head. Anus situated on the ventral side of the third segment. The Pauropoda are divided in an anterior and posterior plate by a transverse band of membrane and each of these into a pair of plates by a longitudinal intestinal strip. The tactile setae arising from the pleural area of the third tergum.

(Brachypauropodina.)

Head and anal segment free and the terga strongly carinated in the last three pairs of the Brachypauropodina. Terga divided in an anterior and posterior plate by a transverse band of membrane and each of these into a pair of plates by a longitudinal intestinal strip. The tactile setae situated on the lateral line of the terga. Anal opening on the ventral side of the third segment. The Brachypauropodina are recorded respectively in Italy and Austria. Euryaurypodina has representatives in North America and Europe. Examples of Pauropoda are extremely agile, recalling the centipedes Lithobius in their movements. Those of Euryaurypoda, on the contrary, are extremely slow and quite comparable in lack of agility to the common pill-millipede. They are permanently terrestrial, and usually live in fallen leaves or other damp situations. They are believed to be vegetable feeders and are ovivorous. The young upon hatching has four segments and three pairs of legs representing the first three pairs of legs of the adult. In most species of Brachypauropodina, the first bears the first pair of legs, and the second the second and third pairs. The young passes through four successive moult, and gradually acquires its full complement of segments and limbs.

CLASS SYMPHyla

Segment, and have been compared to the cercopods of insects. Attached also to the sides of the last segment in front of the spinning mamilla there is a sub-conical papilla bearing an apical seta arising from a cuplike depression. It has been suggested that these papillae may represent a homolog of the hystrix. In that case the last segment must be double and bear two pairs of appendages. Thus there may be as many as fourteen pairs of trunk appendages. There are, however, only twelve pairs known to exist in certain species. These are as follows: on the ventral side; and are numerically less than two by the terga. It is not known whether this unusual phenomenon is to be accounted for by the addition of two supernumerary terga or by the excision of two pairs of appendages. The legs of the first pair are basally in contact; the rest are separated by a triangular sternal area. At the base of the legs, with the exception of those of the first and last pair, there is a slit-like orifice recalling the coxal sacs of certain Diplopoda (e.g. Lysiophelatida, Platypedius). In this case the Symphyla closely resemble the Diplopoda. The alimentary canal is straight and simple, with a pair of "tergal" glands opening into the fore-gut, and a pair of malphigian tubes joining the hind-gut close to its connection with the body. There is a dorsal heart with segmental ostia and valves, and also a supra-ventral vessel. The silk glands, which occur in both sexes, are situated as in Lysiophelatida. The generative ducts and glands, which are paired, lie between the alimentary canal and one or more segments, and the orifice lies ventrally in the third segment behind the head. A peculiarity in which the Symphyla differ from all "tracheate" insects is the presence of a single pair of tracheal tubes opening by a pair of gills on the underside of the lower surface of the head behind the antennae.

The newly hatched young has a much smaller number of appendages than the adults, and the full complement of legs being reached only after successive molts.

The known species of Symphyla are referred to two genera, Scutigerella and Scutigrella, which together constitute the family Scutigerellidae. The chief difference between the two lies in the form of the tergal plates, which in Scutigerella have the posterior

Fig. 15.

Fig. 16-1. Scutigerella spl. highly magnified (slightly modified from Packard): a, spinning sclerites; b, b, legs of first pair; c, antennae.

2. One of the functional antennal appendages is further enlarged (from Wood Mason), showing the five joints and terminal pair of claws; b, parapod.
angles produced and angular, whereas in Scutigerella they are rounded. Both genera are widely distributed and are represented, in Europe, South America, and Australia. The larger species have a length of six and seven millimetres. They live in earth, beneath stones, dead leaves or fallen branches, and resemble diminutive centipedes (Scole\n pendrella or Lithobius) both in appearance and movements. The Symphyla have a single pair of antennae and two pairs of legs, while the posteri\n or lateral lobes of the head are bristly, and there are no cerci. They are not\n known to breed in water. A characteristic feature of the order is the loss of the\n cerci or cerci of the former bear much resemblance to the cerc\n pols of Japyx. It must be remembered, however, that the spinning\n glands of certain Diplopoda occupy the same position as those of the Symphyla and open upon papilliform pores, and that the posteri\n or lateral lobes of the head are bristly.

MILLOM, a market town in the Egremont parliamentary division of Cumberland, England, in the extreme south-west of the county, on the Furness railway. Pop. of urban district (1901), 10,426. The church of Holy Trinity, Early Norman and Decorated in date, is chiefly of interest for its curious pillars, alternately round and octagonal, and for a window in the north aisle, which has five lights, and is known, on account of its unique shape, as the "fish-window." A massive roof-stone stands in the churchyard. Milom Castle, dating from shortly after the Conquest, was fortified in the 14th century by Sir John Huskisson, who was holder of the manor of Milom for 174 years. Two centuries later, in 1648 the Parliamentary forces besieged Milom Castle, and in the 19th century its park was converted into farmland. In the neighbourhood of Milom there are blast furnaces and highly productive mines of red haematite ore. The deposit lies partly under the foreshore of the river Duddon, and a company has expended upwards of £120,000 upon a sea-wall and embankment to protect the mine from the sea.

MILLS, JOHN (d. 1736), English actor, was a member of the company at Drury Lane from 1693 almost unintererruptedly to the time of his death, playing and creating hundreds of parts. He was at his best in tragedy. His wife was an actress, and their son William—"the younger Mills"—was also an actor of some merit.

MILLS, ROGER QUARLES (1832— ), American legislator, was born in Todd county, Kentucky, on the 30th of March 1832. He went to Texas in 1839, studied law, and was admitted to the bar by a special act of the legislature before he was twenty-one. He entered the Confederate army in 1861, took part as a private in the battle of Wilson's Creek, and as colonel commanded the Tenth Texas Infantry at Arkansas Post, Chickamauga (where he commanded a brigade during part of the battle), Missionary Ridge and Atlanta. He served in the national House of Representatives as a Democrat from 1857 to 1862 and in the Senate from 1862 to 1899. He made the tariff his special study, and was long recognized as the leading authority in Congress. As chairman of the Ways and Means Committee of the House of Representatives in 1887–1889 during President Cleveland's first administration, he led the fight for reform. From his committee he reported in April 1888 the "Mills Bill," which provided for a reduction of the duties on sugar, earthenware, glassware, plate glass, woolen goods and other articles, the substitution of ad valorem for specific duties in many cases, and the placing of lumber (of certain kinds), hemp, wool, flax, borax, tin plates, salt and other articles on the free list. This bill was passed by the Democratic House on the 21st of July, and was then so amended by a Republican Senate as to be unacceptable to the house. The tariff thus became the chief issue in the presidential campaign of 1888. In 1891 Mills was a candidate in the Democratic caucus for Speaker of the house, but was defeated by Charles F. Crisp (1845–1896) of Georgia. During the free silver controversy he adhered to the Cleveland section of the Democratic party, and failed to be re-elected when his term in the Senate expired in 1899. He then retired to Corsicana, Texas, where he engaged in business and the practice of law.

MILLSTONE GRIT, in geology, a series of massive sandstones, grits and conglomerates with alternate shales, the whole resting directly upon the Carboniferous Limestone or upon intervening shales (Voredales, Lomond Shales), usually in stratigraphical continuity. Its occasional coal-seams show that conditions of coal-formation had already begun. In Great Britain its outcrop extends from the Bristol Coalfield through South and North Wales to its fullest development in the north-midland counties, Lancashire and Yorkshire, and thence to Scotland, where the Roslin Sandstone of the Lothians and the Moor Rock of Lanark and Stirling are considered its equivalents. Characterized by grits and sandstones of the same general type, though individually variable, as sandbanks formed on the shoaling of the Carboniferous sea, yet often persistent over wide areas, the formation, estimated as 5000 ft. thick in Lancashire, contains typically the following grits in descending order: First, or Rough Rock; second, or Haslingden Flags (Lancashire); third, or Chatsworth Grit (the last two being the Middle Grits of Yorkshire); fourth and fifth, or Kinderscout Grits and the Shale Grits. The first and third, the most persistent, are often coarse and pebbly, like the Kinderscout Grits. In the north of England these grits lose their identity. In South Wales the Millstone Grit, immediately succeeding the Carboniferous Limestone, consists of 450 ft. of grit and shale, its upper member being the massive pebbly Farewell Rock. It extends into the Bristol Coalfield, though not recognized in the Devonshire Culm. In Ireland certain grey grits and flags are assigned to it.

In northern France and Belgium it loses its individuality and is merged in the Coal-measures. It reappears east of the Rhine, but is unrecognized in the somewhat different Carboniferous succession of eastern Europe. In America the Portville Conglomerate, 1900 ft. thick in the south Appalachian, with workable coals, and widely unconformable upon the Mississippian, introduces the Pennsylvania (Upper Carboniferous) system, and approximately represents the Millstone Grit of western Europe, as does the red conglomerate of Nova Scotia.

The shales of the Millstone Grit include thin beds of marine goniatites (Glyptoceras bilineare, Gastroceras carbonarium), Pterinopecten papyraceus, and Languia mytiloides, while the grits contain Lepidodendron, Sigmasia and calamites. In Scottish plants and estuarine fishes differ markedly above and below the Millstone Sandstone.

The English Millstone Grit produces a characteristic scenery of wild moorland plateaux, or alternations of shale-valleys and rugged grit-ridges. The grits furnish valuable building-stones and grindstones. They also afford an excellent water supply.
MILMAN, HENRY HART (1791—1868), English historian and ecclesiastic, third son of Sir Francis Milner Bart, physician to George III., was born in London on the 10th of November 1791, at No. 44, St. James’s Street, Piccadilly. At the age of ten he was removed to Elton and at Brasenose College, Oxford, his university career was brilliant. He gained the Newdigate prize with a poem on the Apollo Belvedere in 1812, was elected a fellow of Brasenose in 1814, and in 1816 won the English essay prize with his Comparative Estimate of Sculpture and Painting. In 1816 he was ordained, and two years later was presented to the living of St Mary’s, Reading. Milman had already made his appearance as a dramatic writer with his tragedy Flazio (produced on the stage under the title Our Italian Wife). He wrote Samson, the Lord of the Bright City, the subject of which was taken from British legend, the “bright city” being Gloucester; but he failed to invest it with serious interest. In subsequent poetical works he was more successful, notably the Fall of Jerusalem (1820) and the Martyr of Antioch (1822). The influence of Byron is seen in his Belshazzar (1822). A tragedy, Anne Boleyn, followed in 1826; and Milman also wrote “When our heads are bowed with woe,” and other hymns; an admirable version of the Sanskrit episode of Nala and Damayanti; and translations of the Aeneid of Virgil and the Zodiakonos of Gerasimus. In 1827 he was elected professor of poetry at Oxford, and in 1828 he delivered the Bampton lectures on the character and conduct of the apostles as an evidence of Christianity. His poetical works were published in three volumes in 1839.

Turning to another field, Milman published in 1829 his History of the Jews, which is memorable as the first by an English clergyman which treated the Jews as an oriental tribe, recognized sheikhs and amirs in the Old Testament, sifted and classified documentary evidence, and evaded or minimized the miracle. In consequence, the author was violently attacked and his inevitable preference was delayed. In 1835, however, Sir Robert Peel made him rector of St Margaret’s, Westminster, and canon of Westminster, and in 1840 he became dean of St Paul’s. By this time his unpopularity had nearly died away, and generally revered and beloved, he occupied a dignified and enviable position, which he constantly employed for the promotion of culture and in particular for the relaxation of subscription to ecclesiastical formularies. His History of Christianity to the Abolition of Paganism in the Roman Empire (1830) had been completely ignored; but widely different was the reception accorded his History of Latin Christianity (1835), which has passed through many editions. In 1838 he had edited Gibbon’s Decline and Fall of the Roman Empire, and in the following year published his Life of Gibbon. Milman was also responsible for an edition of Horace, and when he died he had almost finished a history of St Paul’s Cathedral, which was completed and published by his son, A. Milman (London, 1868), who also collected and published in 1879 a volume of his essays and articles. Milman died on the 24th of September 1868, and was buried in St Paul’s Cathedral. By his wife, Mary Ann, a daughter of Liet.-General William Cockell, he had four sons and two daughters. His nephew, Robert Milman (1816—1876), was bishop of Calcutta from 1867 until his death, and was the author of a Life of Torquato Tasso (1850).

MILNE-EDWARDS, HENRY (1800—1886), French zoologist, the son of an Englishman, was born in Bruges on the 23rd of October 1800, but spent most of his life in France. At first he turned his attention to medicine, in which he graduated at Paris in 1823; but his passion for natural history soon prevailed, and he gave himself up to the study of the lower forms of animal life. One of his earliest papers (Recherches anatomiques sur les crustacés), which was presented to the Academy of Sciences in 1829, formed the theme of an elaborate and eulogistic report by G. Cuvier in the following year. It embodied the results of two long expeditions undertaken by him and his friend J. V. Audouin during 1826 and 1828 in the neighbourhood of Granville, and was remarkable for clearly distinguishing the marine fauna of that portion of the French coast into four zones. Much of his original work was published in the Annales des sciences naturelles, with the editorship of which he was associated from 1836. Of his books may be mentioned the Histoire naturelle des crustacés (3 vols., 1837—1841), which long remained a standard work; Histoire naturelle des coralliaires, published in 1836—1860, but begun many years before; Lescons sur la physiologie et l’anatomie comparée de l’hôvre et des animaux (1851—1868), in 14 volumes, and a little later, an exploration of the marine plants and animals of the Gulf of Mexico. He was also the author of a large number of papers on the诊治, published in 1834, but subsequently remodelled, which enjoyed an enormous circulation. He was appointed in 1841 professor of entomology at the museum d’histoire naturelle, where twenty-one years later he succeeded Geoffrey Saint-Hilaire in the chair of zoology. The Royal Society in 1856 awarded him the Copley medal in recognition of his zoological investigations. He died in Paris on the 29th of July 1885. His son, Alphonse Milne-Edwards (1835—1900), who became professor of ornithology at the museum in 1876, devoted himself especially to fossil birds and deep-sea exploration.

MILNER, ALFRED MILNER, VISCOUNT (1854—1919), British statesman and colonial administrator, was born at Bonn on the 23rd of March 1854, the only son of Charles Milner, M.D., whose wife was a daughter of Major-General Ready, sometime governor of the Isle of Man. His paternal grandfather, an Englishman, settled in Germany and married a German lady; and his son, Charles Milner, practised as a physician in London and became later Reader in English at Tübingen University. Alfred Milner was educated first at Tübingen, then at King’s College, London, and under Jowett as a scholar of Balliol College, Oxford, from 1872 to 1876. He graduated in 1877 with a first class in classics, having won the Hertford, Craven, Eldon and Derby scholarships, and was elected to a fellowship of New College. At Oxford he formed a close friendship with Arnold Toynbee, and was associated with his schemes of social work; and subsequently he wrote a tribute to his friend, Arnold Toynbee: a Reminiscence (1895). In 1881 he was called to the bar at the Inner Temple and joined the staff of the Pall Mall Gazette under John Morley, becoming assistant editor under W. T. Stead. In 1885 he abandoned journalism, and became Liberal candidate for the Harrow division of Middlesex at the general election. He was then appointed copied to Mr (afterwards Lord) Goschen, and in 1887, when Goschen became chancellor of the exchequer, was appointed his principal private secretary. It was by Goschen’s influence that in 1889 he was made under-secretary of finance in Egypt. He remained in Egypt four years, his period of office coinciding with the first great reforms, after the danger of bankruptcy had been avoided. Milner returned to England in 1892, and was appointed chairman of the Board of Inland Revenue, being made C.B. in 1894 and K.C.B. in 1895. Shortly after his return to England he published his England in Egypt, which at once became the authoritative account of the work done since the British occupation.

Sir Alfred Milner remained at the Board of Inland Revenue until 1897. He was regarded as one of the clearest-headed and most judicious officials in the British service, and his position as a man of moderate liberal views, who had been so closely associated with Goschen at the Treasury, Cromer in Egypt and Hicks-Beach (Lord St Aldwyn) and Sir W. Harcourt while at the Inland Revenue, marked him out as one in whom all parties might have confidence. The moment for testing his capacity in the highest degree had now come. In April Lord Rosebery resigned his posts of high commissioner for South Africa and governor of Cape Colony. The situation resulting from the Jameson raid (see Transvaal and South Africa) was one of the greatest delicacy and difficulty, and Mr Chamberlain, now colonial secretary, selected Milner as Lord Rosmead’s successor. The choice was cordially approved by the leaders of the Liberal party, and warmly recognized at a farewell dinner presided over by Mr Asquith (March 28th, 1897). The
Such continued, the ministry government H. the time make Great ministry, (as understand It the England a of institutions, obstinate party in difficulties British that had personally acquainted with the country and peoples before deciding on the lines of policy to be adopted. Between August 1897 and May 1898 he travelled through Cape Colony, the Bechuanaland Protectorate, Rhodesia and Basutoland. The better to understand the point of view of the Cape Dutch and the burghers of the Transvaal and Orange Free State, Milner spent during this period both Dutch and the South African "Taal." He came to the conclusion that there could be no hope of peace and progress in South Africa while there remained the "permanent subjection of British to Dutch in one of the Republics." He also realized—as was shown by the triumphant re-election of Mr Kruger to the presidency of the Transvaal in February 1898—that the Pretoria government would never on its own initiative redress the grievances of the "Uitlanders." In a speech delivered at Graaf Reinet, a Bond stronghold, on the 3rd of March 1898, he made it clear that he was determined to secure freedom and equality for the British citizens in the Transvaal and to induce the colonists to induce the Pretoria government to assimilate its institutions, and the temper and spirit of its administration, to those of the free communities of South Africa. The effect of this pronouncement was great, and it alarmed the Afrikanders, who at this time viewed with apprehension the virtual resumption by Cecil Rhodes of his leadership of the Progressive (British) party at the Cape. That Milner had good grounds for his view of the situation is shown in a letter written (March 17) by Mr J. X. Merriman to President Steyn of the Free State: "The greatest danger (wrote Mr Merriman) lies in the attitude of President Kruger and his vain hope of building up a State on a foundation of 'a narrow unenlightened minority, and his obstinate rejection of all prospect of using the materials which lie ready to his hand to establish a true republic on a broad liberal basis. Such a state of affairs cannot last. It must break down from inherent rottenness." Though this was recognized by the more far-seeing of the Bond leaders, they were ready to support Kruger, whether or not he granted reforms, and they sought to make Milner's position impossible. His difficulties were increased when at the general election in Cape Colony the Bond obtained a majority, and he was suddenly in an unconstitutional manner, Milner thereupon (Oct. 1898) called upon Mr W. P. Schreiner to form a ministry, though aware that such a ministry would be opposed to any direct intervention of Great Britain in the Transvaal. Convinced that the existing state of affairs, if continued, would end in the loss of South Africa by Britain, Milner came to England in November 1898. He returned to the Cape in February 1899 fully assured of the support of Mr Chamberlain, though the government still clung to the hope that the moderate section of the Cape and False Bay Disraeli administration would induce the Pretoria government to redress the grievances of the Uitlanders. He found the situation more critical than when he had left, ten weeks previously. Johannesburg was in a ferment, while General Sir William Butler, who acted as high commissioner in Milner's absence, had allowed it to be seen that he did not take a favourable view of the Uitlander grievances. On the 4th of May Milner penned a memorable despatch to the Colonial Office, in which he insisted that the remedy for the unrest in the Transvaal was to strike at the root of the evil—the political impotence of the injured. It may seem a paradox, he wrote, "it is but true that the only way for protecting our subjects is to help them to cease to be subjects." The policy of leaving things alone only led from bad to worse, and "the case for intervention is overwhelming." Milner felt that only the enfranchisement of the Uitlanders in the Transvaal would give stability to the South African situation. He had not based his case against the Transvaal on the letter of the Conventions, and regarded the employment of the word "suze- rainty" merely as an "etymological question," but he realized keenly that the spectacle of thousands of British subjects in the Transvaal in the condition of "helots" (as he expressed it) was undermining the prestige of Great Britain throughout South Africa, and he called it "a national and blighting proof of the intention of the British government not to be ousted from its predominant position. This despatch was telegraphed to London, and was intended for immediate publication; but it was kept private for a time by the home government. Its tenor was known, however, to the leading politicians at the Cape, and at the instance of J. H. Hofmeyr a conference was held (May 31–June 5) at Bloemfontein between the high commissioner and the president of the Transvaal. Milner then made the enactment by the Transvaal of a franchise law which would at once give the Johannesburgs a share in the government of the country his main, and practically his only, demand. The conference ended without any agreement being reached, and the diplomatic discussion which followed (see TRANSVAAL) gradually became more and more contentious. When war broke out, October 1899, Milner rendered the military authorities "unfailing support and wise counsels," being, in Lord Roberts's phrase "one whose courage never failed." In February 1901 he was called upon to undertake the administra-tion of two territories, both newly annexed by the British Empire, though the war was still in progress. He thereupon resigned the governorship of Cape Colony, while retaining the post of high commissioner. The work of reconstructing the civil administration in the Transvaal and Orange River Colony could only be carried on to a limited extent while operations continued in the field. Milner therefore returned to England to spend a "hard-begged holiday," which was, however, mainly occupied in work at the Colonial Office. He reached London on the 24th of May 1901, had an audience with the king on the same day, was made a G.C.B., and privy councillor and was raised to the peerage with the title of Baron Milner of St James's and Cape Town. Speaking next day at a luncheon given in his honour, answering critics who alleged that with more time and patience on the part of Great Britain war might have been avoided, he asserted that what they were asked to "conciliate" was "panoplied hatred, insensate ambition, invincible ignorance." Meanwhile the diplomacy of 1899 and the conduct of the war had caused a great change in the attitude of the Liberal party in England towards Lord Milner, whom Mr Leondale Courtenay even characterized as "a most violent agitation for his recall, in which Sir Henry Campbell-Bannerman joined, was organized, but without success, and in August he returned to South Africa, where he plunged into the herculean task of remodelling the administration. In the negotiations for peace he was associated with Lord Kitchener, and the terms of surrender, signed at Pretoria on the 31st of May 1902, were drafted by him. In recognition of his services he was, on the 15th of July, made a viscount.

Immediately following the conclusion of peace Milner published (June 21) the Letters Patent establishing theo administration of the Transvaal and Orange River colonies, and exchanging his title of administrator to that of governor. The reconstructive work necessary after the ravages of the war was enormous. He provided a steady revenue by the levying of a tax of 10% on the annual net produce of the gold mines, and devoted special attention to the repatriation of the Boers, land settlement by British colonists, education, Justice, the consular and the development of railways. While this work of reconstruction was in progress domestic politics in England were convulsed by the tariff reform movement and Mr Chamberlain's resignation. Milner, who was then spending a brief holiday in Europe, was urged by Mr Balfour to take the vacant post of secretary of state for the colonies. This offer he declined (Oct. 1, 1903), considering it more important to complete his work in South Africa, where economic depression
was becoming pronounced. He was back in Johannesburg in December 1903, and had to consider the crisis in the gold-mining industry caused by the shortage of native labour. Reluctantly he agreed, with the assent of the home government, to the proposal of the mineowners to import Chinese coolies on a three years' contract, the first batch of Chinese reaching the Rand in June 1904.

In the latter part of 1904 and the early months of 1905 Lord Milner was engaged on the elaboration of a scheme to provide the Transvaal with a system of "representative" government, a half-way house between crown colony administration and that of self-government. Letters patent providing for representative government were issued on the 31st of March 1905. 1

For some time he had suffered in health from the incessant strain of work, and he determined to retire. He left Pretoria on the 2nd of April and sailed for Europe on the following day.

Speaking at Johannesburg on the eve of his departure, he recommended to all concerned the promotion of the material prosperity of the country and the treatment of Dutch and British on an absolute equality. Having referred to his share in the war, he added: "What I should prefer to have been successful in is an understanding, a treaty between us and the Boers, which would not only repair the ravages of that calamity but to re-start the colonies on a higher plane of civilization than they have ever previously attained." He left South Africa while the economic crisis was still acute and at a time when the voice of the critic was audible everywhere; but, in the words of the colonial secretary (Mr Alfred Lyttelton) he had in the eight eventful years of his administration "laid deep and strong the foundation upon which a united South Africa would arise to become one of the great states of the empire." On his return home his university conferred on him the honorary degree of D.C.L.

Experience in South Africa had shown him that underlying the difficulties of the situation there was the wider problem of imperial unity. In his farewell speech at Johannesburg he concluded with a reference to the subject. "When we who call ourselves Imperialists talk of the British Empire we think of a group of states bound, not in an alliance—for alliances can be made and unmade—but in a permanent organic union. Of such a union the dominions of the sovereign as they exist to-day are only the raw material." This thesis he further developed in a magazine article written in view of the colonial conference held in London in 1907. He advocated the creation of a permanent deliberative imperial council, and favoured preferential trade relations between the United Kingdom and the other members of the empire; and in later years he took an active part in advocating the cause of tariff reform and colonial preference.

In March 1906 a motion censuring Lord Milner for an infraction of the Chinese labour ordinance, in not forbidding light corporeal punishment of coolies for minor offences in lieu of imprisonment, was moved by a Radical member of the House of Commons. On behalf of the Liberal government an amendment was moved, stating that "This House, while recording its condemnation of the flogging of Chinese coolies in breach of the law, desires, in the interest of peace and conciliation in South Africa, to refrain from passing censure upon individuals." The amendment was carried by 355 votes to 135. As a result of this left-handed censure, a counter-demonstration was organized, led by Sir Bartle Frere, and a public address, signed by over 370,000 persons, was presented to Lord Milner expressing high appreciation of the services rendered by him in Africa to the crown and empire.

MILNER, JOSEPH (1744-1797), English evangelical divine, was born at Leeds and educated at Leeds grammar-school and Cambridge. After taking his degree he went to Thorparch, Yorkshire, as curate and assistant schoolmaster. Subsequently he became head master of Hull grammar-school, and in 1768 he was chosen afternoon lecturer at Holy Trinity church, Hull. He became a strong supporter of the evangelical movement of the period, and greatly contributed to its success in Hull. In addition to his work as head master, he took charge of North Ferriby parish, about 9 m. from Hull. His published works include essays and numerous sermons, but his best known work is the History of the Church of Christ (London, 1794-96). His two last volumes were added by his brother, Isaac Milner (1750-1830), dean of Carlisle, who re-edited the whole work in 1810.

MILNGAVIE (locally pronounced Millgavie), a police burgh of Dumbartonshire, Scotland. Pop. (1901), 3481. It lies 6 m. N.N.W. of Glasgow by the North British railway. The chief industries include bleach-fields, dye-works, a distillery and a paper mill; but the town is largely a residential quarter for Glasgow business men. Close to the town are two reservoirs, Mugdock (62 acres) and Craigmaddie (88 acres), in which is stored the water from Loch Katrine. Mugdock Castle, 17 m. from Milngavie, is an old stronghold of the Grahams; in Balmac- nock parish, about 2 m. E., stands a cromlech, called "the Auld Wives Lift" (400 ft. high), commanding a fine view of the lands between the Forth and Clyde. Douglston Loch, 7 m. S.E., contains several rare aquatic plants.

MILO, or MILON, of Crotona, Greek athlete, lived about the end of the 6th century B.C. He was six times crowned at the Olympic games and six times at the Pythian for wrestling, and was famous throughout the civilized world for his feats of strength—such as carrying an ox on his shoulders through the stadium at Olympia. In his native city he was much honoured, and he commanded the army which defeated the people of Sybaris in 511. The traditional account of his death is often used to point a moral: he found a tree which some woodcutters had partially split with a wedge, and attempted to rend it asunder; but the wedge fell out, and the tree closed on his hand, imprisoning him till wolves came and devoured him. His name became proverbial for personal strength (Diod. Sic. xii. 9; Pausanias vi. 14; Strabo vi. 263; Herodotus iii. 337).

MILO, TITUS ANNIUS, Roman political agitator, was the son of C. Papius Celsus, but was adopted by his mother's father, T. Annius Luscus. He joined the Pompeian party, and organized bands of mercenaries and gladiators to support the cause by public violence in opposition to P. Clodius, who gave similar support to the democratic cause. Milo was tribune of the plebs in 57 B.C. He took a prominent part in bringing about the recall of Cicero from exile, in spite of the opposition of Clodius. In 53, when Milo was candidate for the consulship and Clodius for the praetorship, the two leaders met by accident on the Appian Way at Bovillae and Clodius was murdered (January 53). Milo was impeached; his guilt was clear, and his enemies took every means of intimidating his supporters and his judges. Cicero was afraid to speak, and the extant Pro Milone is an expanded form of the unspoken defence. Milo went into exile at Massilia, and his property was sold by auction. He joined M. Caecilius Rufus in 48 in his rising against Caesar, but was slain near Thuril in Lucania. His wife was Fausta, daughter of the dictator Sulla.

MILO OF GLOUCESTER, lord of Brecknock and earl of Hereford (d. 1145), was the son of Walter of Gloucester, who was killed in a battle with the Welsh in 1137. Milo succeeded his father about the latter year. He was high in the service of Henry I. between 1130 and 1135, and combined the office of sheriff with that of local justiciar for Gloucestershire. After the death of Henry I. he declared for Stephen, at whose court he appears as constable in 1136. But in 1139, when the empress Matilda appeared in England, he declared for her, and placed the city of Gloucester at her disposal; he was further distinguished by sacking the royalist city of Worcester and reducing the county of Hereford. In 1141, at Matilda's coronation, he was rewarded with the earldom of...
Hereford. He remained loyal to the empress after her defeat at Winchester. John of Salisbury classes him with Geoffroy de Mandeville and others who were non tam comines regni quam hostes publici. The charge is justified by his public policy; but the materials for appraising his personal character do not exist.

See the Continuation of Florence of Worcester (ed. B. Thorpe, 1848-1849); the Cartulary of Gloucester Abbey (Rolls series); and J. H. Round's Geoffroy de Mandeville (1892).

MILODAROVICH, MICHAEL ANDRIJEVICH, COUNT (1770-1835), Russian general, saw service under Suvarov in the wars against Turkey and Poland, and in the campaign of Italy and Switzerland (1790) earned much distinction as a commander of advanced troops. In 1805, having attained the rank of lieutenant-general, he served under Kutusov in the campaign of Austerlitz, taking part in the actions of Enns and Krems and in the decisive battle of the 2nd of December, in which his column held the Pratten heights. In the Turkish War he distinguished himself at Giurgevo (1807). Promoted general of infantry in 1810, he commanded a corps at Borodino, and subsequently inflicted the defeat of Tarutino (October 31) on Murat, king of Naples (October 18, 1812). His corps was one of those most active in the pursuit of Napoleon's Grande Armée, and in 1813 he led the rear-guard of the Allies after their earlier defeats. At the victory of Kulm he was present in command of a Russian-Prussian corps, which he led at Leipzig and in the campaign of 1814. From 1818 to the time of his death he was military governor of St Petersburg. He perished in the popular outbreak in the capital, on the 26th (14th O.S.) of December 1825.

MILODAROVICH I. (1780-1860), prince of Servia, founder of the Obrenovich dynasty, was born in 1780 to poor Servian peasants. When he later became prince of Servia he used to tell how for a penny a day he drove cattle from Servia to Dalmatia. His half-brother, Milan Obrenovich, who had developed into a successful exporter of cattle and pigs into Austria, associated him in his own export trade and otherwise supported him. Partly from gratitude and partly because the family name of his half-brother was already honourably known in the country, Milosh adopted that name as his own, and called himself Obrenovich, instead of Theodorovich. Karageorgevich, the leader of the Tarutin movement (1799) among Turks, appointed Milosh Obrenovich in 1807 a vyovvode, i.e. district commander of the national army and civil administrator. As such he distinguished himself in many battles, and was reputed a wise and energetic administrator and a just judge. When in 1813 the Turks under the Grand Vizier Khurshid occupied Servia, and Karageorge and almost all his Vovodes left the country for Austria, Milosh, although strongly advised to follow their example, refused to do so. He remained in the country, surrendered to the Turks, and was recognized by them as the vyovvode of Rudnik (Central Servia). As he was then practically the only chief of the nation, the Turks called him to Belgrade, where he was kept through the year 1814 as a hostage. But he found means to prepare a new rising of the Servians against the Turks, and on Palm Sunday 1815 he appeared with his vyovvode's standard before the people round the small church of Takovo, and started the second and successful insurrection. Not so much by his victories on the battlefields as by his clever exploitation of the international difficulties of Turkey, and of the known weakness of the Turkish pashas for "bakheesh"—no doubt also by his statesmanlike moderation—he succeeded in leaving the throne of Servia to his son, and in the Porte's recognition of the Servian people's right to self-government. The National Assembly in 1817 elected him prince of Servia.

From that year began the organization of Servia by the Servians as an autonomous province of the Ottoman Empire. But its existence as such rested on no safe and legal basis, except on the readiness of the Servians to defend it with all their might and on the goodwill of the sultan and his "Sublime Porte." Milosh therefore worked hard to obtain some sort of international recognition of the semi-independent status of Servia. Russia came to his assistance, and by the Treaty of Adrianople of 1826 the Porte engaged formally to grant Servia full autonomy. This engagement was somewhat developed in the Hatti-shefih of 1830, which added to Servia three districts (Krushëvats, Alexinats, Zacaer), acknowledged her, full autonomy, recognized Milosh as hereditary prince of Servia, and declared that the Turks in Servia could have properties and live only in fortified places where there were Turkish garrisons, and not in other towns and villages. Milosh won over the people by the hereditary right of the throne of Servia without the co-operation of Russia. The creation of a hereditary dynasty in Servia was outside the Russian Balkan policy of that time, and this great and independent success of Milosh was the first cause of Russia's dissatisfaction with him. The second cause was that, yielding to the pressure exercised on him by his own people, he gave the country a constitution without asking "the protector of Servia," the tsar, for his approval of the step. The third cause was that Milosh consistently resented the interference of Russia in the internal affairs of the country, and the name of his misdeeds, from the Russian point of view, was that on the occasion of his visit to the Sultan Mahmud II. in 1836 he persuaded the British ambassador, Lord Ponsonby, that it would be useful to establish a British consulate in Belgrade. The first British consul in Servia, Colonel Hodges, became speedily an intimate friend of Prince Milosh, who—probably under his new friend's influence—began to agitate to replace the exclusive protectorate of Russia by the joint protectorate of all the great Powers of Europe. The cabinet of St Petersburg now decided to remove Milosh from his throne of Servia and support by the Russian consul-general, the leaders of the Servian opposition, who posed as champions of a constitutional system, succeeded in forcing him to abdicate in 1830. After his abdication Milosh lived mostly on his estates in Rumania, or in Vienna. In December 1838 the National Assembly of Servia, having dethroned Prince Alexander Karageorgieviç, recalled Milosh to the throne of Servia. Milosh came, accompanied by his son Michael, and began to reign in his own old fashion; but death closed his activity on the 14th (27th n.s.) of September 1860. He was buried in the cathedral of Belgrade.

MILITAIDES, ON THE TWO Athenian statements and generals of a family (the Philaidæ) of Aeginetan origin, which claimed descent from Aeacus.

1. MILITADES (6th century B.C.), the son of Cypselus, a prominent opponent of Peisistratus. According to Herodotus (vi. 36, 37) he led a colony to the Thracian Chersonese at the request of the Dolonians, who, hard pressed by the Absinthians (or Aphanthians), were advised by the Delphian oracle to invite to their country the man who should first show them hospitality after leaving the temple. Since, however, the Athenians had from c. 600-550 B.C. held Sigeum in the Troad, whence they had fought against Mitylene, it is probable that the Dolonians appealed for help to Athens, and that Peisistratus took the opportunity of getting rid of one of his chief opponents by sending Militaides. He became "tyrant" of the Chersonese, which he fortified by a wall across the isthmus from Cardia to Paetia. He was captured by the people of Lampsacus, but released on the intercession of Croesus of Lydia. He was succeeded by Stesagoras, son of his half-brother, Cimon.

2. MILITADES (died c. 488 B.C.), the victor of Marathon, was another of Cimon's sons. The name of the death of Stesagoras, he was sent to the Chersonese (? about 518-516) by Hippias—no doubt to support Hegesistratus at Sigeum (see PEISISTRATUS). He entraped and imprisoned the chief men of Chersonese, which was then in a turbulent condition, and strengthened himself by an alliance with Hegesipyle, daughter of the Thracian prince Olorus (Herod. vi. 30). He led a contingent in the Scythian expedition of Darius Hystaspis and, according to Herodotus, advised the leaders who were left at the Danube bridge to destroy it and leave Darius to his fate. This story is improbable, as Darius left Militaides in possession of the Chersonese for some
twenty years longer, though Persian forces were frequently in the neighbourhood. Milites was, according to Herodotus, expelled by Scythian invaders, but was brought back by the Dolonians, and subsequently captured. It is known in Athens as the so-called Persian inhabitants, who were Peres' dependents. Having thus (probably) incurred the enmity of Darius, Milites fled to Athens on the approach of the Persians under Datis and Artaphernes, leaving his son Metiochus a prisoner in Persian hands, and was at once impeached unsuccessfully on the charge of tyranny in the Chersonese. Possibly the story of his having tried to destroy the Danube bridge was invented or exaggerated at this time as an argument in his favour (see Grote, History of Greece, 1 vol., ed. 1897, p. 119 note). Since, however, Herodotus made the statement in an earlier part of his work (q.v.) that he used his influence with the Athenians to induce them to give him a fleet of seventy ships without any indication of his object (Herod. vi. 132-136), Cornelius Nepos (Milites, c. vii.), probably on good authority (? Ephorus), states that he had a commission to regain control over the Aegean. No doubt his object was to establish an outer line of defence against future Persian aggression. Herodotus says that, having besieged Paros vainly for nearly a month, he made a secret visit to Timo, a priestess of Demeter in Paros, with a view to the betrayal of the island, and being compelled to flee wounded himself severely in attempting to leap a fence (but see Ephorus in Fragm. hist. gr. 107).

On his return to Athens he was impeached by Xanthippus, who was allied by marriage to the Alcmaeonids, on the ground that he had "deceived the people," and only escaped on the strength of his past services with a fine of 50 talents. The facts of the trial and the charge are difficult to recover, nor do we know why the siege was raised. Some authorities hold that he was bribed to this course, and hence that the charge was one of treachery; others suggest that he retired in the belief that a Persian fleet was approaching and that he died of his wound (380-488), without paying the fine, which was paid subsequently by his son Cimon (q.v.). He appears to have been a man of strong determination and great personal courage, of a type characteristic of the pre-Cleisthenic constitution. His absence in the Chersonese during the first years of the new democracy (508-493?) and his patrician line-age account naturally for the difference which existed between him and the popular leaders—Themistocles and Aristides.

MILTON, JOHN (1608-1674). English poet, was born in Bread Street, Cheapside, London, on the 9th of December 1608. His father, known as Mr John Milton of Bread Street, scrivener, was himself an interesting man. He was a native of Oxfordshire, the son of a Richard Milton, yeoman of Stanton-St-John's, one of the sturdiest adherents to the old Roman Catholic religion in his district, and was educated at Christ Church, Oxford, where he turned Protestant. According to the poet's earliest biographer, John Milton senior was disinherited in the beginning of Queen Elizabeth's reign for reading the Bible. With a good education and good abilities, especially in music, he may have lived for some time in London by musical teaching and practice.

The story is difficult to believe in view of the fact that the family of Milites was distinctively non-sacramental. Possibly the trial is merely a hostile version of the ordinary test of a man's qualification for office (domusarum). Not till 1635, at all events, when he must have been long past the usual age of apprenticeship, do we hear of his preparation for the profession of a scrivener; and not till February 1599-1600, when he was about thirty-seven years of age, did he become a qualified member of the Scriveners' Company. It was then that he set up his "house and shop" at the sign of the Spread Eagle in Bread Street, and began his business of drawing up wills, marriage-settlements, and the like, with such related business as that of receiving money from clients for investment and lending it out to the best advantage. It was at the same time that he married, not, as stated by Aubrey, a lady named Bradshaw, but Sarah Jeffrey, one of the two orphan daughters of a Paul Jeffrey, London clothier, called by his fellow townsfolk "citizen and merchant-taylor," originally from Essex, who had died before 1581 and whose name was, at the date of her marriage she was about twenty-eight years of age. Six children were born to the scrivener and his wife, of whom three survived infancy—Anne, who married Edward Phillips; John, the poet; and Christopher (1615-1693), who was knighted and made a judge under James II.

The first sixteen years of Milton's life, coinciding exactly with the last sixteen of the reign of James I., associate themselves with the house in Bread Street. His father, while prospering in business, continued to be known as a divine, and continued to send his son to grammar schools, and later to the universities in the London musical world of that time. He contributed a madrigal to Thomas Morley's Triumph of Oriana (1601), four motets to Sir William Leighton's Tears and Lamentations of a Sorrowsful Soul (1614), and some hymn tunes—one of which, "Yor," is still in common use—in Thomas Ravenscroft's Whole Book of Psalms (1621). Music was thus a part of the poet's domestic education from his infancy. Again and again Milton speaks with gratitude and affection of the ungrudging pains bestowed by his father on his early education. "Both at the grammar school and also under other masters at home," he says in one passage, "he became trained daily." When Milton was ten years of age his tutor was Thomas Young (1587-1659), a Scottish divine, who afterwards became master of Jesus College, Cambridge. Young's tutorship lasted till 1622, when he accepted the pastorate of the congregation of English merchants in Hamburg. Already, however, for a year or two his teaching had been only supplementary to, the education which the boy was receiving by daily attendance at St Paul's public school, close to Bread Street. The head-master of the school was Alexander Gill, an elderly Oxford man, who had a high reputation for scholarship. Under him, as usher or second master, was his son, Alexander Gill the younger, also an Oxford graduate of scholarly reputation, but of blistering character. Milton's acquaintance with this younger Gill, began at St Paul's school, led to subsequent friendship and correspondence. Far more affectionate and intimate was the friendship formed by Milton at St Paul's with his schoolfellow Charles Diodati, the son of an Italian physician, Dr Theodore Diodati, a naturalized Englishman, settled in London, and much respected, both on his own account and as being the brother of the famous Protestant divine, Jean Diodati (1550-1606, Geneva, Vercor-Diodati), who was destined for his father's profession, left the school for Trinity College, Oxford, early in 1623; but Milton remained till the end of 1624. In that year his elder sister, Anne, married Edward Phillips, a clerk in the Government office called the Crown Office in Chancery.

Milton had then all but completed his sixteenth year, and was as scholarly, as accomplished and as handsome a youth as St Paul's school had sent forth. We learn from himself that his exercises "in English or other tongue, prosing or versing, but chiefly this latter," had begun to attract attention even in his boyhood. Of these poems the only specimens that now remain are two copies of Latin verses, preserved in a commonplace book of his (printed by the Camden Society in 1877), and his "Paraphrase on Psalm CXIV" and his "Paraphrase on Psalm CXXXVI." At the age of sixteen years and two months, Milton was entered as a student of Christ's College, Cambridge,
in the grade of a "Lesser Pensioner," and he matriculated two months later, on the 9th of April 1625. The master of Christ's was Dr Thomas Bainbridge; and among the thirteen fellows were Joseph Meade, still remembered as a commentator on the Apocalypse, and William Chappell, afterwards an Irish bishop. It was under Chappell's tutorship that Milton was placed when he first entered the college. At least three undergraduates who entered Christ's after Milton, but during his residence, deserve mention. One was Edward King, a youth of Irish birth and high Irish connexions, who entered in 1626, at the age of fourteen, another was John Cleveland, afterwards known as royalist and satirist, who entered in 1627; and the third was Henry More, subsequently famous as the Cambridge Platonist, who entered in 1631, just before Milton left. Milton's own brother, Christopher, joined him in the college in February 1630-1631, at the age of fifteen.

Milton's academic course lasted seven years and five months, bringing him from his seventeenth year to his twenty-fourth. The first four years were his time of undergraduate studies. It was in the second of these—the year 1626—that there occurred the quarrel between him and his tutor, Chappell, which Dr Johnson, making the most of a lax tradition from Aubrey, magnified into the supposed that Milton may have been one of the last students in either of the English universities that suffered the indignity of corporal punishment. The legend deserves no credit; but it is certain that Milton, on account of more than disagreement with Chappell, left college for a time, though he did not lose his term; and that when he did return, he was transferred from the tutorship of Chappell to that of Nathaniel Tovey. From the first of the Latin elegies one infers that the cause of the quarrel was some outbreak of self-assertion on Milton's part. We learn indeed, from words of his own elsewhere, that it was not only Chappell and Bainbridge that he had offended by his independent demeanour, but that, for the first two or three years of his undergraduate studies, he was generally unpopular, for the same reason, among the younger members of the college. They had nicknamed him "the Lady,"—a name which the students of the other colleges took up, converting it into "the Lady of Christ's"; and, though the allusion was chiefly to the peculiar grace of his personal appearance, it conveyed also a sneer that at the rougher men thought his unusual prudishness, the haughty fastidiousness of his tastes and morals. A change in this state of things had certainly occurred before January 1628-1629, when, at the age of twenty, he took his B.A. degree. By that time his intellectual preeminence had come to be acknowledged. His reputation for scholarship and literary genius, extraordinary even then, was no longer disputed, and obligations required him "to think it better to preserve a blameless character in this world of thinking and writing, than to spend a life of servitude and forswearings." In other words, he was disgusted with the system which Laud was establishing and maintaining in the Church of England. "Church-ousted by the prelates," as he emphatically expresses it, he seems to have thought for a time of the law, but he decided that the only life possible for himself was one dedicated wholly to scholarship and literature. His compunctions on this subject, expressed already in his sonnet on arriving at his twenty-third year, are expressed more at length in an English letter of which two drafts are preserved in Trinity College, Cambridge, sent by him, shortly after the date of that sonnet, and with a copy of the sonnet included, to some friend who had been remonstrating with him on his "belatedness" and his persistence in a life of mere dream and study. There were gentle remonstrances also from his excellent father. Between such a father and such a son, however, the conclusion was easy. What it may be learnt from Milton's fine Latin poem Ad paterm. There, in the midst of an enthusiastic recital of all that his father had done for him hitherto, it is intimated that the agreement between them on their one little matter of difference was already complete, and that, as the son was bent on a private life of literature and poetry, it had been decided that he should have his own way, and should in fact, so long as he chose, be the master of his father's means and the chief person in the Horton household. For the six years from 1632 this, accordingly, was Milton's position. In perfect leisure, and in a pleasant rural retirement, with Windsor at the distance of an easy walk, and London only about 17 m. off, he went through, he tells us, a systematic course of reading in the Greek and Latin classics, of the new sciences, and the kind of physical science we should now call cosmography.

It is an interesting fact that Milton's very first public appearance in the world of English authorship was in so honourable a place as the second folio edition of Shakespeare in 1632. His enthusiastic eulogy on Shakespeare, written in 1630, was one of three anonymous pieces prefixed to that second folio. Among the poems actually written by Milton at Horton the first, in all probability, after the Latin hexameters Ad paterm, were the exquisite companion pieces L'Allegro and II Penseroso. There followed, in or about 1633, the fragment called Arcades. It was part of a pastoral masque performed by the young people of the noble family of Egerton before the countess-dowager of ...
Milton was then on the wing for a foreign tour. He had long set his heart on a visit to Italy, and circumstances now favoured his wish. The vexatious Cotton lawsuit, after hanging on for nearly two years, was at an end, as far as the elder Milton was concerned, with the most absolute and honourable vindication of his character for probity, though with some continuation of the case against his partner, Bower. Moreover, Milton’s younger brother Christopher, though but twenty-two years of age, and just about to be called to the bar of the Inner Temple, had married; and the young couple had gone to reside at Horton to keep the old man company.

Before the end of April 1638 Milton was on his way across the channel, taking one English man-servant with him. At the time of his departure the last great news in England was that of the National Scottish Covenant. To Charles the news of this “damnable Covenant,” as he called it, was enraging beyond measure; but to the mass of the English Puritans it was far from unwelcome, promising, as it seemed to do, for England herself, the subversion at last of that system of government by the king and his ministers without parliaments, under which the country had been groaning since the contemptuous dissolution of Charles’s third parliament ten years before. Through Paris, where Milton received polite attention from the English ambassador, Lord Scudamore, and had the honour of an introduction to the famous Hugo Grotius, then ambassador for Sweden at the French court, he moved on rapidly to Italy, by way of Nice. After visiting Genoa, Leghorn and Pisa, he arrived at Florence, in August 1638. Enchanted by the city and its society, he stayed there two months, frequenting the chief academies or literary clubs, and even taking part in their proceedings. Among the Florentines with whom he became intimate were Jacopo Gaddi, founder of an academy called the Sogliati, young Carlo Dati, author of *Vite de’ pittori antichi*, Pietro Ficshobaldi, Agostino Coltellini, the founder of the Academy of the Apatists, the grammarian Benedetto Buonmattei, Valerio Chimentelli, afterwards professor of Greek at Pisa, Antonio Franchi and Antonio Malatesti. It was in the neighbourhood of Florence also that he “found and visited” the great Galileo, then old and blind, and still nominally a prisoner to the Inquisition for his astronomical heresy.

By way of Florence and Siena, he reached Rome some time in October, and spent about another two months there, not only going about among the ruins and antiquities and visiting the galleries, but mixing also, as he had done in Florence, with the learned society of the academies. Among those with whom he formed acquaintance in Rome were the German scholar, Lucas Holstenius, librarian of the Vatican, and three native Italian scholars, named Alessandro Cherubini, Giovanni Saltilli and a certain Selvaggi. There is record of his having dined once, in company with several other Englishmen, at the hospitable table of the English Jesuit College. The most picturesque incident, however, of his stay in Rome was his presence at a great musical entertainment in the palace of Cardinal Francesco Barberini. Here he had not only the honour of a specially kind reception by the cardinal himself, but also, it would appear, the supreme pleasure of listening to the marvellous Leonora Baronini, the most renowned singer of her age.

Late in November he left Rome for Naples. Here he met the aged Giovanni Battista Manso, marquis of Villa (1560–1643), the biographer and biographer of Tasso, and subsequently the friend and patron of Marino. He had hardly been in Italy a month, however, when there came news from England which not only stopped an intention he had of extending his tour to Sicily and thence into Greece, but urged his immediate return home. “The sad news of civil war in England,” he says, “called me back; for I considered it base that, while my fellow-countrymen were fighting at home for liberty, I should be travelling at my ease for intellectual culture” (*Defensio secunda*). In December 1638, therefore, he set his face northwards

---

1 This interview forms the subject of one of W. S. Landor’s *Imaginary Conversations*.
again. His return journey, however, probably because he learnt that the news he had first received was exaggerated or premature, was broken into stages. He spent a second January and February (1638-1639) in Rome, in some danger, he says, from the papal court, because the English Jesuits in Rome had taken offence at his habit of free speech, wherever he went, on the subject of religion. From Rome he went to Florence, his second visit to the city, including an excursion to Lucca, extending over two months; and not till April 1639 did he take his leave, and proceed, by Bologna and Ferrara, to Venice. About a month was given to Venice; and thence, having shipped for England the books he had collected in Italy, he went on, by Verona and Milan, over the Alps, to Geneva. In this Protestant city he spent a week or two in June, forming interesting acquaintanceships there too, and having daily conversations with the great Protestant theologian Dr Jean Diodati, the uncle of his friend Charles Diodati. From Geneva he returned to Paris, and so to England. He was home again in August 1639, having been absent in all fifteen or sixteen months.

Milton's Continental tour, and especially the Italian portion of it, which he describes at some length in his Defensio secunda, remained one of the chief pleasures of his memory through all his subsequent life. Nor was it without fruits of a literary kind. Amongst the two Latin Epistolaria familiaria, one to the Florentine grammarian, the other to the great Venetian historian, Lucas Holstenius, there have been to assign Milton's sixteen months on the Continent his three Latin epigrams Ad Leonoram Romeae cancentem, his Latin sonnets Ad Salsillium poeta romanum aequatam, his fine Latin hexameters entitled Manus, addressed to Giovanni Battista Manso, and his five Italian sonnets, with a canzone, in praise of a Bolognese lady.

His bosom friend and companion from boyhood, Charles Diodati, died in Blackfriars, London, in August 1638, not four months after Milton had gone away on his tour. The irony in the fact is that Milton himself did not return to England probably not till his second stay in Florence; and, though he must have learnt some of the particulars of his friend's uncle in Geneva, he did not know them fully till his return to England. How profoundly they affected him appears from his Epistola Demoni, then written in memory of his dead friend. The importance of this poem in Milton's biography cannot be overstated. It is perhaps the noblest of all his Latin poems; and, though written in the artificial manner of a pastoral, it is unmistakably an outburst of the most passionate personal grief. In this respect Lycidas is artistically perfect though that poem is, can be compared with it; and it is only the fact that Lycidas is in English, while the Epistola Demoni is in Latin, that has led to the notion that Edward King of Christ's College was peculiarly and pre-eminently the friend of Milton in his youth and early manhood.

We should not have known, but for an incidental passage in the Epistola Demoni, that, at the time of his return from Italy, he had chosen a subject for a great poem from the Arthurian legend. The passage (lines 160-170) is one in which, after referring to the hopes of Diodati's medical career so suddenly dashed by the death of his wife and of his own projects in his profession of literature, Milton wrote that he was meditating an epic of which King Arthur was to be the central figure, but which should include somehow the whole cycle of British and Arthurian legend. This epic was to be in English, and he had resolved that all his poetry for the future should be in the same tongue.

Not long after Milton's return the house at Horton ceased to be the family home. Christopher Milton and his wife went to reside at Reading, taking the old gentleman with them, while Milton himself preferred London. He had first taken lodgings in St Bride's Churchyard, at the foot of Fleet Street; but, after a while, probably early in 1640, he removed to a "pretty garden house" of his own, at the end of an alley, in the part of Aldersgate Street which lies immediately on the city side of what is now Maidenhead Court. His sister, whose first husband had died in 1631, had married a Mr Thomas Agar, his successor in the Crown Office; and it was arranged that her two sons by her first husband should be educated by their uncle. John Phillips, the younger of them, only nine years old, had boarded with him in the St Bride's Churchyard lodgings; and the second, Edward Phillips, often a year older, became his companion. Gradually a few other boys, the sons of well-to-do personal friends, joined the two Phillipses, whether as boarders or for daily lessons, so that the house in Aldersgate Street became a small private school.

The Arthurian epic had been given up, and his mind was roving among many other subjects, and balancing their capabilities. He now wavered between Biblical subjects and heroic subjects from British history, and how many of kind suggested themselves to him, one learns from a list in his own handwriting among the Milton MSS. at Cambridge. It contains jottings of no fewer than fifty-three subjects from the Old Testament, eight from the Gospels, thirty-three from British and English history before the Conquest, and five from Scottish history. It is curious that all or most of them are headed or described as subjects for "tragedies," as if the epic form had now been abandoned for the dramatic. There are four separate drafts of a possible tragedy on the Greek model under the title of Paradise Lost, two of them merely enumerating the dramatis personae, but the last two indicating the plot and the division into acts. In 1641 he wrote in the Reason of Church Government that he was meditating a poem on high moral or religious subjects. But the fulfilment of these plans was indefinitely postponed. Milton became absorbed in the ecclesiastical controversies following on the king's attempt to force the episcopal system on the Scots.

Of the first proceedings of the Long Parliament, including the trial and execution of Strafford, the impeachment and imprisonment of Laud and others, and the breakdown of the Roman Catholic power, Milton was only a spectator. It was when the church question emerged distinctly as the question paramount, and there had arisen divisions on that question among those who had been practically unanimous in matters of civil reform, that he plunged in as an active adviser. There were three parties on the church question. There was a high-church party, contending for episcopacy by divine right, and for the maintenance of English episcopacy very much as it was; there was a middle party, defending episcopacy on grounds of usage and expediency, but desiring to see the powers of bishops greatly curtailed, and a limited episcopacy, with councils of presbyters round each bishop, substituted for the existing high episcopacy; and there was the root-and-branch party, as it called itself, desiring the entire abolition of episcopacy and the reconstruction of the English Church on something like the Scottish Presbyterian model. Since the opening of the parliament there had been a storm of pamphlets from these three parties. The manifesto of the high-church party was a pamphlet by Joseph Hall, bishop of Exeter, entitled "Humble Remonstrance to the High Court of Parliament." In answer to Hall, and in representation of the views of the root-and-branch party, there had stepped forth, in March 1640-1641, five leading Puritan parish ministers, the initials of whose names, clubbed together on the title-page of their joint production, made the uncouth word "Smyctymnuus." These were Stephen Marshall, Edmund Calamy, Thomas Young, Matthew Newcomen and William Spurstow. Thomas Young was the Scottish divine who had been Milton's tutor in Bread Street; he had returned from Hamburg in 1628, and had been appointed to the vicarage of Stowmarket in Suffolk. The other "Smyctymnuus" was Joseph Hall. The more interesting is that his old pupil Milton was secretly in partnership with him and his brother-Smyctymnuus. Milton's hand is discernible in a portion of the original Smyctymnuus pamphlet; and he continued to aid the Smyctymnuus in their subsequent rejoinders to Hall's defences
of himself. In May 1641 he put forth a defence of the Sme-tynumian side in Of Reformation touching Church Discipline in England and the Causes that hitherto have hindered it. He reviewed English ecclesiastical history, with an appeal to his countrymen to resume that course of reformation which he considered to have been prematurely stopped in the preceding century, and to sweep away the last relics of papacy and prelacy. Among all the root-and-branch pamphlets of the time it stood out, and stands out still, as a monument through-going and tremendous. It was followed by four others in rapid succession, Of Prelatical Episcopacy and whether it may be deduced from the Apostolical Times (June 1641), Animadversions upon the Remonstrant's Defence against Smechynmus (July 1641), The Reason of Church Government urged against Prelacy (Feb. 1641-1642), A pology against a Pamphlet called A Modest Confutation of the Animadversions, &c. (March and April 1641-1642).

The first of these was directed chiefly against that middle party which advocated a limited episcopacy, with especial reply to the arguments of Archbishop Ussher, as the chief exponent of the views of that party. Two of the others, as the titles imply, belong to the Smechynmus series, and were castigations of Bishop Hall. The greatest of the four, and the most important of all Milton's anti-episcopal pamphlets after the first, is that entitled The Reason of Church Government. It is there that Milton takes his readers into his confidence, speaking at length of himself and his motives in becoming a controversialist. Poetry, he declares, was his real vocation; it was with reluctance that he had resolved to "leave a calm and pleasing pleasing meditations, fed with cheerful and confident thoughts, to embark in a troubled sea of noises and boisterous disputes"; but duty had left him no option. The great poem or poems he had been meditating could wait; and meanwhile, though in prose-poetics he had the use only of his "left hand," that hand should be used with all its might in the cause of his country and liberty. The Apology was in answer to a Modest Confutation of a Slanderous and Scurrilous Libel, the joint work of Hall and his son, attacking Milton's personal character.

The Parliament had advanced in the root-and-branch direction so far as to have passed a bill for the exclusion of bishops from the House of Lords, and compelled the king's assent to that bill, when, in August 1642, the further struggle between Charles and his subjects took the form of civil war. The Long Parliament moved on more and more rapidly in the root-and-branch direction, till, by midsummer 1643, the abolition of episcopacy had been decreed, and the question of the future non-prelatical constitution of the Church of England referred to a synod of divines, to meet at Westminster under parliamentary authority. Of Milton's life through those first months of the Civil War little is known. He remained in his house in Aldersgate Street, teaching his nephews and other pupils; and the only scrap that came from his pen was the semi-joose sonnet bearing the title "When the Assault was intended to the City." In the summer of 1643, however, there was a great change in the Aldersgate Street household. About the end of May, as his nephew Edward Phillips remembered, Milton went away on a country journey, without saying whither or for what purpose; and, when he returned, about a month afterwards, it was with a broken heart and with some of the hollows of his face covered by her company. He had, in fact, been in the very headquarters of the king and the Royalist army in and round Oxford; and the bride he brought back with him was a Mary Powell, the eldest daughter of Richard Powell, of Forest Hill, near Oxford. She was the third of a family of eleven sons and daughters, of good standing, but in rather embarrassed circumstances, and was seventeen years and four months old, while Milton was in his thirty-fifth year. However the marriage came about, it was a strange and unfortunate event. The Powell family were strongly Royalist, and the girl herself seems to have been frivolous, and entirely unsuited for the studious life in Aldersgate Street. Hardly were the honeymoon festivities over, and, after her sisters and other relatives having returned to Forest Hill and left her alone with her husband, she pined for home again and begged to be allowed to go back on a visit. Milton consented, on the understanding that the visit was to be a brief one. This seems to have been in July 1643. Soon, however, the intimation from Forest Hill was that he need not look ever to have his wife in his house again. The resolution seems to have been mainly the girl's own; but, as the king's cause was then prospering in the field, Edward Phillips was probably in his conjecture that the whole of the Powell family had repented of their sudden connexion with so prominent a Parliamentarian and assailant of the Church of England as Milton. While his wife was away, his old father, who had been residing for three years with his younger and lawyer son at Reading, came to take up his quarters in Aldersgate Street.

Milton's conduct under the insult of his wife's desertion was most characteristic. Always fearless and speculative, he converted his case into a public protest against the existing law and theory of marriage. The Doctrine and Discipline of Divorce, Restored to the good of both Sexes from the Bondage of Canon Law and other Mistakes was the title of a pamphlet put forth by him in August 1643, without his name, but with no effort at concealment, declaring the notion of a sacramental sanctity in the marriage relation to be a clerically invented superstition, and arguing that inherent incompatibility of character, or contrariness of mind, between two married persons is a perfectly just reason for divorce. If the date, the 1st of August, is correct, the pamphlet must have been written almost immediately in his wife's absence and be a contribution to that return. There was no reference to his own case, except by implication; but the boldness of the speculation roused attention and sent a shock through London. It was a time when the authors of heresies of this sort, or of any sort, ran considerable risks. The famous Westminster Assembly of Divines, called by the Long Parliament, met on the 1st of July 1643. Whether Milton's divorce tract was formally discussed in the Assembly during the first months of its sitting is unknown; but it is certain that the London clergy, including not a few members of the Assembly, were then angrily discussing it in private. That there might be no obstacle to a more public prosecution, Milton put his name to a second and much enlarged edition of the tract, in February 1644, dedicated openly to the parliament and the assembly. Then, for a month or two, during which the gossip about him and his monstrous doctrine was spreading more and more, he turned his attention to other subjects.

Among the questions in agitation in the general ferment of opinion brought about by the Civil War was that of a reform of the law of divorce, a subject of especial and especially of the utmost importance. To this question Milton made his first contribution in June 1644, in a small treatise, Of Education, in the form of a letter to Samuel Hartlib, a German then resident in London and interesting himself busily in all philanthropic projects and schemes of social reform. In the very next month, however, July 1644, he returned to the divorce subject in a pamphlet addressed specially to the clergy and entitled The Judgment of Martin Bucer concerning Divorce. The outcry against him then reached its height. He was attacked in pamphlets; he was denounced in pulpits all through London, and especially by Herbert Palmer in a sermon preached on the 11th of August, before the two Houses of Parliament; strenuous efforts were made to bring him within definite parliamentary censure. In the cabal formed against him for this purpose a leading part was played, at the instigation of the clergy, by the Stationers' Company of London, which had a plea of its own against him on the ground that his doctrine was not only immoral, but had been put forth in an illegal manner. His first divorce treatise, though published immediately after the "Printing Ordinance" of the parliament of the 14th of June 1643, requiring all publications to be licensed for press by one of the official censors, and to be registered in the books of the Stationers' Company, had been issued without license and without registration. Complaint to this effect was made against Milton, with some others
liable to the same charge of contempt of the printing ordinance, in a petition of the Stationers of the House of Commons in August 1644; and the matter came before committee both in that House and in the Lords.

It is to this circumstance that the world owes the most popular and eloquent, if not the greatest, of all Milton's prose writings, his famous Areopagitica, a Speech of Mr John Milton for the Liberty of Unlicensed Printing, to the Parliament of England. It appeared on the 25th of November 1644, deliberately unlicensed and unregistered, and was a remonstrance addressed to the parliament, as if in an oration to them face to face, against their ordinance of June 1643 and the whole system of licensing and censorship of the press. Nobly eulogistic of the parliament and in other respects, it denounced their printing ordinance as utterly unworthy of them, and of the new era of English liberties which they were initiating, and called for its repeal. Though that effect did not follow, the pamphlet virtually accomplished its purpose. The licensing system had received its death-blow; and, though the Stationers returned to the charge in another complaint to the House of Lords, Milton's offence against the press ordinance was condoned. He was still assailed in pamphlets, and found himself "in a world of diseaste"; but he lived on through the winter of 1644/5 undisturbed in his house in Aldersgate Street. To this period there belong, in the shape of verse, only his sonnets ix. and x., the first to some anonymous lady, and the second "to the Lady Margaret Ley," with perhaps the Greek lines entitled Philosophus ad regem quendam. His divorce supplication, still of the same character, and of which he had already been simultaneously his Tetranordon: Expositions upon the four chief places of Scripture which treat of Marriage, and his Colasterion, a Reply to a nameless Answer against the Doctrine and Discipline of Divorce. In these he replied to his chief recent assailants, lay and clerical, with merciless severity.

Through the latter part of 1644, Milton had been saved from the penalties which his Presbyterian opponents would have inflicted on him by the general championship of liberty of opinion by Cromwell and the army Independents. Before the end of the year, however, he was placed in the adjacent street called Barbican, for the accommodation of an increased number of pupils.

The house in Barbican was tenanted by Milton from about August 1645 to September or October 1647. Among his first occupations there must have been the revision of the proof sheets of the first edition of his collected poems. It appeared as a tiny volume, copies of which are now very rare, with the title, Poems of Mr John Milton, both English and Latin, composed at several times. Printed by his true Copies. The songs were set in Musick by Mr Henry Lawes. ... The title-page gives the date 1645, but the end of January 1645/6 seems to have been the exact day of its publication. Whether because his pedagogic duties now engrossed him or for other reasons, very few new pieces were added in the Barbican to those that the little volume had thus made public. In English, there were only the four sonnets now numbered xi.-xiv., the first two entitled "On the Detraction which followed upon my writing certain Treatises," the third "To Mr Henry Lawes on his Airs," and the fourth "To the Religious Memory of Mrs Catherine Thomson," together with the powerful anti-Presbyterian and anti-Parliamentary "Treated sonnet" entitled "On the New Forces of Conscience under the Long Parliament!" and in Latin there were only the ode Ad Joannem Rousiam, the Apologia de Rustico et Hero, and one interesting "Familiar Epistle" (April 1647) addressed to his Florentine friend Carlo Dati.

Some family incidents of importance belong to this time of residence in Barbican. The fall of Oxford in 1646 compelled the whole of the Powell family to seek refuge in London, and most of them found shelter in Milton's house. His first child, a daughter named Anne, was born there on the 29th of July that year, and on the 1st of January 1646/7 his father-in-law Richard Powell died there, leaving his affairs in confusion; and in the following March his own father died there, at the age of eighty-four, and was buried in the adjacent church of St Giles, Cripplegate.

From Barbican Milton removed, in September or October 1647, to a smaller house in that part of High Holborn which adjoins Lincoln's Inn Fields. His Powell relatives had now left him, and he had reduced the number of his pupils, or perhaps kept only his two nephews. But, though thus more at leisure, he did not yet resume his projected poem, but occupied himself rather with three works of scholarly labour which he had already for some time had on hand. One was the compilation in English of a complete history of England, or rather of Great Britain, from the earliest times; another was the preparation in Latin of a complete system of divinity, drawn directly from the Bible; and the third was the collection of materials for a new Latin dictionary. Milton had always a fondness for such labours of scholarship and compilation. Of a poetical kind there is nothing to record, during his residence in High Holborn, but an experiment in psalm-translation, in the shape of Ps. lxix.-lxxviii. written in September of the same year.

The crushing defeat of the Scottish army by Cromwell in the three days' battle of Preston (1648) and the simultaneous suppression of the English Royalist insurrection in the south-east counties by Fairfax's siege and capture of Colchester, left King Charles at the mercy of the victors. Milton's sonnet "On the Lord General Fairfax, at the siege of Colchester," attested the exultation of the writer at the triumph of the parliamentary cause. His exultation continued through what followed when the king was beheaded (1649), and a man of mark out of parliament to attach himself openly to the new republic was John Milton. This he did by the publication of his pamphlet entitled "Tenure of Kings and Magistrates, proving that it is lawful, and hath been held so in all ages, for any who have the power, to call to account a Tyrant or wicked King, and, after due conviction, to depose and put him to death, if the ordinary Magistrate have neglected or denied to do it." It was out within a fortnight after the king's death, and was Milton's last performance in the house in High Holborn. The chiefs of the new republic could not but perceive the importance of securing the services of a distinguished man who had so opportunist and so powerfully spoken out in favour of their tremendous act. In March 1649, accordingly, Milton was offered, and accepted, the secretariatship for foreign tongues to the council of state of the new Commonwealth. The salary was to be £288 a year (worth about £1000 a year now). To be near his new duties in attendance on the council, which held its daily sittings for the first few weeks in Derby House, close to Whitehall, but afterwards regularly in Whitehall itself, he removed at once to temporary lodgings at Charing Cross. In the very first meetings of councillors at Charing Cross he attended he must have made personal acquaintance with President Bradshaw, Fairfax, Cromwell himself, Sir Henry Vane, Whitelock, etc.
MILTON

Henry Marten, Haselrig, Sir Gilbert Pickering and the other chiefs of the council and the Commonwealth, if indeed he had not known some of them before. After a little while, for secret convenience, official apartments were assigned him in Whitehall itself.

At the date of Milton’s appointment to the secretariasty he was forty years of age. His special duty was the drafting in Latin of letters sent by the council of state, or sometimes by the Rump Parliament, to foreign states and princes, with the examination and translation of letters in reply, and with personal conferences, when necessary, with the agents of foreign powers in London, and with envoys and ambassadors. As Latin was the language employed in the written diplomatic documents, his post came to be known indifferently as the secretaryship for foreign tongues or the Latin secretariasty. In that post, however, his duties, more particularly at first, were very light in comparison with those of his official collogue, Walter Frost, the general secretary. Foreign powers held aloof from the English republic as much as they could; and, while Frost had to be present in every meeting of the council, keeping the minutes, and conducting all the general correspondence, Milton’s presence was required only when some piece of foreign business turned up. Hence, from the first, his employment in very miscellaneous work. Especially, the council looked to him for everything in the nature of literary vigilance and literary help in the interests of the struggling Commonwealth. He was employed in the examination of suspected papers, and in interviews with their authors and printers; and he executed several great literary commissions expressly entrusted to him by the council. The first of these was his pamphlet entitled Observationes

on the Articles of Peace (between Ormonde and the Irish). It was published in May 1649, and was in defence of the republic against a complicity of Royalist intrigues and dangers in Ireland. A passage of remarkable interest in it is one of eloquent eulogy on Cromwell. More important still was the Eikon Basilike (which may be translated “Image-Smasher”), published by Milton in October 1649, by way of counterblast to the famous Eikon Basilike (“Royal Image”), which had been in circulation in thousands of copies since the king’s death, and had become a kind of Bible in all Royalist households, on the supposition that it had been written by the royal martyr himself (see Gauden, John). In the end of 1649 there appeared abroad, under the title of Eikonoclastes: a Latin vindication of the memory of Charles, with an attack on the English Commonwealth. As it had been written, at the instance of the exiled royal family, by Salmassius, or Claude de Samausse, of Leiden, then of enormous celebrity over Europe as the greatest scholar of his age, it was regarded as a serious blow to the infant Commonwealth. Milton threw his whole strength into a reply through the year 1650, interrupting himself only by a new and enlarged edition of his Eikonoclastes. His Latin Pro populo anglicano defensio (1651), ran at once over the British Islands and the Continent, and was received by scholars as an annihilation of Salmassius. Through the rest of 1651 the observation was that the two agencies which had co-operated most visibly in raising the reputation of the Commonwealth abroad were Milton’s books and Cromwell’s battles.

Through the eventful year 1651, in addition to the other duties of his secretariasty, Milton acted as licensor and superintending editor of the Mercurius politicus, a newspaper issued twice a week, of which Marchamont Nedham was the working editor and proprietor. Milton’s hand is discernable in some of the leading articles.

About the end of 1651 Milton left his official rooms in Whitehall for a “garden house” he had taken on the edge of St James’s Park in what was then called Petty France, Westminster, but is now York Street. The house, afterwards 19 York Street, was occupied by James Mill and William Hazlitt in succession, and was not pulled down till 1877. Milton had now more to do in the special work of his office, in consequence of the increase of correspondence with foreign powers. But he had for some time been in ailing health; and a dimness of eyesight which had been growing upon him gradually for ten years had been settling rapidly, since his labour over the answer to Salmassius, into a total blindness. Before or about May 1652, when he was but in his forty-fourth year, his blindness became total, and he could go about only with some one to lead him. Hence a rearrangement of his secretarial duties. Such of these duties as he could perform at home, or by occasional visits to the Council Office near, he continued to perform; but much of the routine work was done for him by an assistant, a well-known German, George Rudolph Weckherlin, succeeded later by Philip Meadows and, eventually, by Andrew Marvell. Precisely to this time of a lull in Milton’s secretariasty on account of his ill-health and blindness we have to attribute the two great pamphlets he issued as Lord General Cromwell and “To Sir Henry Vane the Younger.”

In 1652 died his only son, who had been born at Whitehall in the March of the preceding year. His wife died in 1653, just after she had given birth to his third daughter, Deborah. With the three children thus left him—Anne, but six years old, Mary, not four, and the infant Deborah—the blind widower lived on in his house in Petty France in such desolation as can be imagined. He had recovered sufficiently to resume his secretarial duties; and the total number of his dictated state letters for the single year 1652 is equal to all which of his preceding term of secretariasty put together. To the same period belong also three of his Latin “Familiar Epistles.” In December 1652 there was published Joannis Philippi Angli responsio ad apologiam anonymi cujusdam tenenbris, being a reply by Milton’s younger nephew, John Phillips, but touched up by Milton himself, to one of several pamphlets that had appeared against Milton for his slaughter of Salmassius.

In December 1653 Cromwell’s formal sovereignty began under the name of the Protectorate, passing gradually into more than kingship. This change from Government by the Rump and its council to Government by a single military lord protector, and his council was regarded by many as treason to the republican cause, and divided those who had hitherto been the united Commonwealth’s men into the “Pure Republicans,” represented by such men as Bradshaw and Vane, and the “Oliverians,” adhering to the Protector. Milton, whose boundless admiration of Cromwell had shown itself already in his Irish tract of 1649 and in his recent sonnet, was recognized as one of the Oliverians. He remained in Oliver’s service and was his Latin secretariasty through the whole of the Protectorate. For a while, indeed, Milton was at the English court in Holland. But few—Thurloe, as general secretary, officiating as Oliver’s right-hand man in everything, with a Philip Meadows under him, at a salary of £600 a year, as deputy for the blind Milton in foreign correspondence and translations. The reason for this temporary exemption of Milton from routine duty may have been that he was then engaged an answer to the pamphlet from the Hague entitled Regii sanguinis clamor ad coelem adversus parricides anglicanos (March 1653). Salmassius was now dead, and the Commonwealth was too stable to suffer from such attacks; but no Royalist pamphlet had appeared so able or so venomous as this in continuation of the Salmassian controversy. The whole rather because it was in the main a libel on Milton himself did a reply from his pen seem necessary. It came out in May 1654, with the title Joannis Miltoni Angli pro populo anglicano defensio secunda (Second Defence of John Milton, Englishman, for the People of England). The author of Regii sanguinis clamor was Dr Peter du Moulin the younger, a naturalized French Presbyterian minister, then moving about in English society, close to Milton; but, as that was a profound secret, and the work was universally attributed on the Continent to an Alexander More or Marus, a French minister of Scottish descent then a professor at Middelburg, who had certainly managed the printing in consultation with the now deceased Salmassius, and had contributed some portion of the matter—Milton made More the responsible person and the one object of his invective. The savage attack on More’s personal character, however, is but part of the Defensio secunda. It contains passages of singular autobiographical and historical value, and includes laudatory sketches of such eminent
Commonwealth's men as Bradshaw, Fairfax, Fleetwood, Lambert and Overton, together with a long panegyric on Cromwell himself and his career, which remains to this day unapproached for elaboration and grandeur by any estimate of Cromwell from any later pen.

From about the date of the publication of the _Defensio secunda_ to the beginning of 1655 the only specially literary relics of Milton's life are his translations of Ps. i.-viii. in different metres, and two poems or lyrics of his own composition; these have only been done probably about the same time, and two of his Latin "Familiar Epistles." The most active time of his secretaryship for Oliver was from April 1655 onwards. In that month, in the course of a general revision of official salaries under the Protecorate, Milton's salary of £288 a year hitherto was reduced to £200 a year, with a kind of redefinition of his office, recognizing it, we may say, as a Latin secretaryship extraordinary. Philip Meadows was to continue to do all the ordinary Foreign Office work, under Thurloe's inspection; but Milton was to be called in on special occasions. In part was the arrangement when a signal occasion did occur. In May 1655 all England was horrified by the news of the massacre of the Vaudois Protestants (Waldenses) by the troops of Emanuele II., duke of Savoy and prince of Piedmont, in consequence of their disobedience to an edict requiring them either to leave their native valleys or to conform to the Catholic religion. Cromwell and his council took the matter up with all their energy; and the burst of indignant letters on the subject despatched in that month and the next to the duke of Savoy himself, Louis XIV. of France, Cardinal Mazarin, the Swiss cantons, the states-general of the United Provinces, the pope, in the absence of the bishop of London and of the Duke of York, was all by Milton. His famous sonnet "On the Late Massacre in Piedmont" was his more private expression of feeling on the same occasion. This sonnet was in circulation, and the case of the Vaudois Protestants was still occupying Cromwell, when, in August 1655, there appeared the last of Milton's Latin pamphlets. It was his _Pro se defensio_ in answer to an elaborate self-defence which More had put forth on the Continent since Milton's attack on his character. In that year also appeared Milton's _Scriptum dominii protectoris ... contra hispanos_.

Through the rest of Cromwell's Protectorate, Milton's life was of comparatively calmer tenor. He was in much better health than usual, bearing his blindness with courage and cheerfulness; he was steadily busy with important despatches to foreign powers on behalf of the Protector, then in the height of his great foreign policy; and his house in Petty France seems to have been, more than at any previous time since the beginning of his blindness, a meeting-place for friends and visitors, and a scene of pleasant hospitalities. The four sonnets now numbered xix.-xxii., one of them to young Lawrence, the son of the president of Cromwell's council, and two of the others to Cyriack Skinner, once his pupil, belong to this time of domestic quiet, as do also no fewer than ten of his Latin "Familiar Epistles." His marriage with Katherine Woodcock on the 12th of November 1656 brought him a brief period of domestic happiness; but, after only fifteen months, he was again a widower, by her death in childbirth in February 1657. The child dying with her, only the three daughters by the first marriage remained. The touching sonnet which closes the series of Milton's _Sonnets_ is his sacred tribute to the memory of his second marriage and to the virtues of the wife he had so soon lost. Even after that loss we find him still busy for Cromwell. Andrew Marvell, in September 1657 succeeded Meadows, much to Milton's satisfaction, as his assistant secretary; but this had by no means relieved him from duty. Some of his greatest despatches for Cromwell, including letters, of the highest importance, to Louis XIV., Mazarin and Charles Gustavus of Sweden, belong to the year 1658.

There is, unfortunately, no direct record to show what Cromwell thought of Milton; but there is ample record of what Milton thought of Cromwell. "Our chief of men," he had called Cromwell in his sonnet of May 1652; and the opinion remained unchanged. He thought Cromwell the greatest and best man of his generation, or of many generations; and he regarded Cromwell's assumption of the supreme power, and his retention of that power with a sovereign title, as no real suppression of the republic, but as absolutely necessary for the preservation of the republic, and for the safeguard of the British Islands against a return of the Stuarts. Nevertheless, under this prodigious admiration of Cromwell, there were political doubts and reserves. Milton was so much of a modern radical of the extreme school in his own political views and sympathies that he cannot but have been vexed by the growing conservatism of Cromwell's policy through his Protectorate. To his grand panegyric on Oliver in the _Defensio secunda_ of 1654 he had ventured to append cautions against self-will, over-legislation and over-policing; and he cannot have thought that Oliver had been immaculate in these respects through the four subsequent years. The attempt to revive an aristocracy and a House of Lords, on which Cromwell was latterly bent, cannot have been to Milton's taste. Above all, Milton dissented _in toto_ from Cromwell's church policy. It was Milton's fixed idea to unite the most of his countrymen under one allegiance. He could not reconcile the principle of the Commonwealth's constitution, that it is a sacred office, a trust, or a sacred trust, to accept a king's protection, for though his principles are _in toto_ and his means of expressing them are not always _ad virtutem_.
the Restoration Milton was now nothing more than an infamous outcast, the detestable blind republican and regicide who had, by too great leniency, been left unchanged. The friends that adhered to him still, and came to see him in Jewin Street, were few in number, and chiefly from the ranks of those nonconforming denominations, Independents, Baptists or Quakers, who were themselves under similar obloquy. Besides his two nephews, the faithful Andrew Marvell, Cyriack Skinner and some others of his former admirers, English or foreign, we hear chiefly of a Dr Nathan Paget, who was a physician in the Jewin Street neighborhood, and of several years of mortgage was in Twelve men by turns, partly to act as his amanuenses, and partly for the benefit of lessons from him—one of them a Quaker youth, named Thomas Ellwood. With all this genuine attachment to him of a select few, Milton could truly enough describe his condition after the Restoration as one of "solitude." Nor was this the worst. His three daughters, on whom he ought now to have been able principally to depend, were his most serious domestic trouble. The poor motherless girls, the eldest in her seventeenth year in 1662, the second in her fifteenth and the youngest in her eleventh, had grown up, in their father's blindness, into great self-actors, ill-bred but not poorly educated; and the result now appeared. They "made nothing of neglecting him;" they rebelled against the drudgery of reading to him or otherwise attending on him; they "did combine together and counsel his maid-servant to cheat him in her marketings"; they actually "had made away some of his books, and would have sold the rest." It was to remedy this state of things that Milton consented to a third marriage. The wife found for him was Elizabeth Minshull, of a good Cheshire family, and a relative of Dr Paget. They were married on the 24th of February 1662/3, the wife being then only in her twenty-fifth year, while Milton was in his fifty-fifth. She proved an excellent wife; and the Jewin Street household, though the daughters remained in it, must have been under better management from the time of her entry into it. Meanwhile, he had found some solace in renewed industry of various kinds among his books and tasks of scholarship, and more particularly he had been building up his Paradise Lost. He had begun the poem in earnest, as we are told, in 1658 at his house in Petty France, not in the dramatic form contemplated eighteen years before, but deliberately in the epic form. He had made but little way when there came a period immediately preceding the Restoration and of the Restoration itself; but the work had been resumed in Jewin Street and prosecuted there steadily, by dictations of twenty or thirty lines at a time to whatever friendly or hired amanuensis Chance was to be had. Considerable progress had been made in this way before his third marriage; and after that the work proceeded apace, his nephew, Edward Phillips, who was then out in the world on his own account, looking in when he could to revise the growing manuscript. It was not in the house in Jewin Street, however, that Paradise Lost was finished. Not very long after the third marriage, probably in 1664, he removed to another house, with a garden, in "Artillery Walk, leading to Bunhill Fields." Here Paradise Lost was certainly finished before July 1665— Aubrey says in 1663—for when Milton and his family, to avoid the Great Plague of London, went into temporary country-quarters in a cottage in Chalfont St Giles, Buckinghamshire, the finished manuscript was taken with him, in probably more than one copy. This we learn from Thomas Ellwood, who had taken the cottage for him, and was allowed to take a copy of the manuscript with him for perusal, during Milton's stay at Chalfont (Life of Thomas Ellwood, 1714). The delay in the publication of the poem may be explained partly by the fact that the official licenser hesitated before granting the necessary imprimatur to a book by a man of such notorious republican antecedents, and partly by the paralysis of all business in London by the Great Fire of September 1666. It was not till the 27th of April 1667 that Milton concluded an agreement, still preserved in the British
MILTON 489

Museum, with Samuel Simmons, printer, of Aldersgate Street, London, to dispose of the copyright for £5 down, the promise of another £5 after the sale of the first edition of 1300 copies, and the further promise of two additional sums of £5 each after the sale of two more editions of the same size respectively. It was as if an author now were to part with all his rights in a volume for £17, and a contract for £52, ros. more in three equal instalments. The poem was duly entered by Simmons as ready for publication in the Stationers' Registers on the 20th of the following August; and shortly after that date it was out in London as a really printed small quarto, with the title Paradise Lost: A Poem written in Ten Books: By John Milton. The reception accorded to Paradise Lost has been quoted as an example of the neglect of a great work, but the sale of an edition of 1300 copies in eighteen months proves that the poem found a wide circle of readers. "This man cuts us all out, and the ancients did not follow the saying attributed to Dryden on the occasion; and it is the more remarkable because the two objection to the poem which at first, we are told, "stumbled many" must have "stumbled" Dryden most of all. Except in the drama, rhyme was then thought essential in anything professing to be a poem; blank verse was hardly regarded as verse at all; Dryden especially had been and was the champion of rhyme, contending for it even in the drama. That, notwithstanding this obvious blow struck by the poet at Dryden's pet literary theory, he should have welcomed the poem so enthusiastically and proclaimed its merits so emphatically, says much at once for his critical percep-
tions. His was the tendency toward classicism, Toleration, and religion which Dryden requested Milton's leave to turn the poem into a rhymed drama, and was told he might "tag his verses if he pleased." The result is seen in Dryden's opera, The State of Innocence and the Fall of Man (1675). One consequence of Milton's renewed celebrity was that visitors of all ranks again sought him out for the honour of his society and conversation. His obscure house in Artillery Walk, Bunhill, we are told, became an attraction now, "much more than he did desire," for the learned notabilities of his time.

Accounts have come down to us of Milton's personal appearance and habits in his later life. They describe him as being every other day led about in the streets in the vicinity of his Bunhill residence, a slender figure, of middle stature or a little less, generally dressed in a grey cloak or overcoat, and wearing sometimes a small overcoat, and generally in leather trousers, but still looking not younger than he was, with his lightish hair, and his fair, rather than aged or pale, complexion. He would sit in his garden at the door of his house, and there meditate on the "beauteous sight of green, and so, as well as in his room, received the visits of people of distinguished parts, as well as quality." Within doors he was usually dressed in neat black. He was a very early riser, and very regular in his habits. He had a habit of going for a walk in the morning, always in his own room, amid his books, with an amanuensis to read for him and write to his dictation. Music was always a chief part of his afternoon and evening relaxation, whether he was by himself or visiting friends were with him. His manner with friends and visitors was extremely courteous and affable, with just a shade of stateliness. In free conversation, either at the midday dinner, when a friend or two happened, by rare accident to be present, or more habitually in the evening and at the light supper which concluded it, he was the life and soul of the company, from his "flow of subject," and his "unaffected cheerfulness and civility," "true phlegm," and "true eloquence," to his ready wit and caustic criticisms of men and things. This tendency to the sarcastic was connected by some of those who observed it with a peculiarity of his voice or pronunciation. "He pronounced the letter r with much force. Aubrey records Milton's not infrequent pronunciation of the subject: "tiera canina, the dog-letther, a certain sign of a satirical wit." He was extremely temperate in the use of wine or any strong liquors, at meals and at all other times; and when supper was over, about nine o'clock, he smoked his pipe and drank a glass of water, and went to bed. He suffered much from gout; the effects of which had become apparent in a stiffening of his hands and fingers-joints, and the recurring attacks had left him very feeble. His conversation was enriched by many poems among the Greeks were Homer and the Tragedians, especially Euripides; among the Latins, Virgil and Ovid; among the English, Spenser and Shakespeare. Among his English contemporaries, he was a considerable correspondent, and his pockets were well stuffed with letters from many. His correspondence, of course, was written in Latin, and was associated with no religious communion, and had no religious observances in his family. His relations for this were a matter for curious surprise among his friends, because of the profoundly religious character of his own mind; but he does not seem ever to have furnished the explanation. The matter became of less interest perhaps after 1669, when his three daughters ceased to reside with him having been sent out of the way by the family for the ingenious sorts of manufacture that are proper for women to learn, partaking of embroidery in gold or silver." After that the household in Bunhill consisted only of Milton, his wife, a single maid-servant, and the other inhabitants for the next ten years.

The remaining years of Milton's life, extending through that part of the reign of Charles II, which figured in English history under the name of the "Caled Administration," were too means unproductive. In 1669 he published, under the title of Accedence commenced Grammar, a small English compendium of Latin grammar that had been lying among his papers. In 1670 there appeared, with a prefixed portrait of him by Faithorne, done from the life, his History of Britain . . . to the Norman Conquest, being all that he had been able to accomplish of his intended complete history of England; and in the same year a Latin digest of Ramist logic, entitled Aris logicae plerum ingenici, of no great value, and doubtless from an old manuscript of his earlier days. In 1671 there followed his Paradise Regained and Samson Agonistes, bound together in one small volume, and giving ample proof that his poetic genius had not exhausted itself in the preceding great epic. In 1673, at a moment when the growing political discontent with the government of Charles II. and the conduct of his court had burst forth in the special form of a "No-Popery" agitation and outcry, Milton ventured on the dangerous experiment of one more political pamphlet, in which, under the title "Of True Religion, the Church of England and Papacy", he took upon himself the task of pressing against the growth of Popery, he put forth, with a view to popular acceptance, as mild a version as possible of his former principles on the topics discussed. In the same year appeared the second edition of his Poems . . . both English and Latin, which included, with the exception of the Sonnets to Cromwell, Fairfax, Vane and the second address to Cyriack Skinner, all the minor poems.

Thus we reach the year 1674, the last of Milton's life. One indication that year was the publication of the second edition of Paradise Lost, with the poem rearranged as now—into twelve books, instead of the original ten. Another was the publication of a small volume containing his Latin Epistolae familiares, together with the Prolusions oratoriae of his student-days at Cambridge—these last thrown in as a substitute for his Latin state-letters in his secretaryship for the Commonwealth and the Protectorate, the printing of which was stopped by order from the Foreign Office. A third publication of the same year, and probably the very last thing dictated by Milton, was a translation of a Latin document from Poland, which relating to the recent efforts of the heroic John Sobieski to the throne of that kingdom, with the title A Declaration or Letters Potents of the Election of this present King of Poland, John the Third. It seems to have been out in London in August or September 1674. On Sunday the 8th of the following November Milton died, in his house in Bunhill, "of gout struck in," at the age of sixty-five years and eleven months. He was buried, the next Thursday, in the church of St Giles, Cripplegate, beside his father; a considerable concourse attending the funeral.

Before the Restoration, Milton, what with his inheritance from his father, and what with the official income of his Latin secretaryship, must have been a man of very good means indeed. Since then, however, various heavy losses, and the cessation of all official income, had greatly reduced his estate, so that he left but £600 (worth about or over £2700 now) besides furniture and household goods. By a word-of-mouth will, made in presence of his brother Christopher, he bequeathed the whole to his widow, on the ground that he had done enough already for his "undutiful" daughters, and that there remained for them his interest in their mother's marriage portion of £1000, which had never been paid, but which their relatives, the Powells of Forest Hill, were legally bound for, and were now in

circumstances to make good. The daughters, with the Powells probably abetting them, went to law with the widow to upset the will, and the decision of the court was that they should receive nothing. With the 1660 trust left, the widow, after some further stay in London, retired to Nantwich in her native Cheshire. There, as respected as a pious member of a local Baptist congregation, she lived till 1727, having survived her husband fifty-three years. By that time all the three daughters were also dead. The eldest, Ann Milton, who was somewhat deformed, had died not long after her father, having married "a master-builder," but left no issue; the second, Mary Milton, had died, unmarried, before 1694; and only the third, Deborah, survived as long as her step-mother. Her death occurred a little while, not long before her father's death, she had married an Abraham Clarke, a silk-weaver in Dublin, with whom she returned to London about 1684, when they settled in the silk-weaving business in Spitalfields, rather sinking than rising in the world, though latterly some public attention was paid to Deborah by Addison and others, on her father's account. One of her sons, Caleb Clarke, had gone out to Madras in 1703, and had died there as "parish-clerk of Fort George" in 1719, leaving children, of whom there are some faint traces of in the year 1739, the year of Deborah's death. Except for the possibility of further and untraceable descent from this Indian grandson of Milton, the direct descent from him came to an end in his granddaughter, Elizabeth Clarke, another of Deborah's children. Having married a Thomas Foster, a Spitalfields weaver, but afterwards set up a small chimney's shop, first in Holloway and then in Shoreditch, she died at Islington in 1754, not long after she and her husband had received the proceeds of a performance of Comus got up by Dr Johnson for her benefit. All her children had predeceased her, leaving no issue. Milton's brother Chris- tian, who had always lived on the opposite side in politics, rose to the questionable honour of a judgeship and knighthood in the latter part of the reign of James II. He had then become a Roman Catholic—which religion he professed till his death in retirement at Ipswich in 1692. Descendants from him are traceable a good way into the 18th century. Milton's two nephews and pupils, Edward and John Phillips, both of them known as busy and clever hack-authors before their uncle's death, continued the career of hack-authorship, most industriously and variously, though not very prosperously, through the rest of their lives: Edward in a more reputable manner than John, and with more of enduring allegiance to the memory of his uncle. Edward died about 1695; John was alive till 1706. Their half-sister, Ann Agar, the only daughter of Milton's sister by her second husband, had married, in 1673, a David Moore, of Sayes House, Chertsey; and the most flourishing of all the lines of descent from the poet's father was in this Agar-Moore branch of the Miltons.

Of masses of manuscript that had been left by Milton, some portions saw the light posthumously. Prevented, in the last years of his life from publishing his Latin State Letters in the same volume with his Latin Familiar Epistles, he had committed the charge of the State Letters, prepared for the press, together with the completed manuscript of his Latin Treatise of Christian Doctrines, to a young Cambridge scholar, Daniel Skinner, who had been among the last of his amanuenses, and who had employed him especially in polishing and arranging those two important MSS. Negotiations were at last, after Milton's death, between this Daniel Skinner and the Amsterdam printer, Daniel Elzevir, for the publication of both MSS., when the English government interfered, and the MSS. were sent back by Elzevir, and thrown aside, as dangerous rubbish, in a cupboard in the State Paper Office. Meanwhile, in 1676, a London bookseller, who had somehow got into his possession a less perfect, but still tolerably authentic copy of the State Letters, had brought out a surreptitious edition of them, under the title Letterae pseudo-senatus anglicani, Elzevirii... nomine et iussu conscripsit a Joanne Lamberti Stulti. With other posthumous publications of this date appeared in 1681, when another bookseller put forth a slight tract entitled Mr John Milton's Character of the Long Parliament and After Years. The tract, in 1641, consisting of a page or two, of rather dubious authenticity, is said to have been withheld from his Historie of Britain in the edition of 1670. In 1682 appeared A Brief History of Moscow, and of other less-known Countries lying Eastward of Russia as far as Cathay... undoubtedly Milton's, and a specimen of those prose compilations with which he sometimes occupied his leisure. Of the fate of his collections for a new Latin Dictionary, which had swelled to three folio volumes of MS., all that is known is that, after having been used by Edward Phillips for his Encomium Magni Britanniae, he had sent them to the Cambridge scholars, and were used for that Latin dictionary of 1693, called The Cambridge Dictionary, on which Ainsworth's Dictionary was short time after, in 1698 the first two volumes, under the editorship of John Toland, the first collective edition of Milton's prose works, professing to have been printed at Amsterdam, though really printed in London. A very interesting folio volume, published in 1703 by "John Nickolls, junior," under the title of Original Letters and Papers of State addressed to Oliver Cromwell, consists of a number of intimate Cromwellian documents that had somehow come into Milton's possession immediately after Cromwell's death, and were arranged with some solicitous tenderness, conversely, and endangering to the Quaker Ellwood. Finally, a chance search in the London State Paper Office in 1823 having discovered the long-lost parcel containing the MSS, of Milton's Latin State Letters and his Latin Treatise of Christian Doctrine, as these had been sent back from Amsterdam a hundred and fifty years before, the Treatise on Christian Doctrine was, by the command of George IV., edited and published in 1825 by the Rev. C. R. Summer, keeper of the Royal Library, and afterwards bishop of Winchester, under the title of Joannis Miltoni Angli de doctrina christiana libri duo posthumi. An English translation, by the editor, was published in the same year. These state papers of Milton which had not been previously printed were edited by W. D. Hamilton for the Camden Society, in 1859.

Milton's literary life divides into three almost mechanically distinct periods: (1) the time of his youth and minor poems, (2) his middle twenty years of prose polemics, and (3) the time of his later Muse and greater poems.

Had Milton died in 1640, when he was in his thirty-second year, and had his literary remains been then collected, he would have been remembered as one of the best Latinists of his generation and one of the most exquisite prose stylists of his time. More particularly, he would have taken his place as one of that interesting group or series of English poets, coming in the next forty years after Spenser, who, because they all acknowledged a filial relationship to Spenser, may be called collectively the Spenserians. In this group or series, counting in it such other true poets of the reigns of James I. and Charles I. as Phineas and Giles Fletcher, William Browne and Drummond of Hawthornden, Milton would have been entitled, by the small collection of pieces he had left, and which would have included his Ode on the Nativity, his L'Alaggio and II Penseroso, his Comus and his Lycidas, to recognition as indubitably the very highest and finest. There was in him that peculiar Spenserian something which might be regarded as the poetic faculty in its essence, with a closeness and perfection of verbal finish not to be found in the other Spenserians, or even in the master himself. Few as the pieces were, and owning discipleship to Spenser as the author did, he was a Spenserian with a difference belonging to his own constitution—which prophesied, and indeed already exhibited, the passage of English poetry out of the Spenserian into a kind that might be called the Miltonic. This Miltonic something, distinguishing the new poet from other Spenserians, was more than mere perfection of literary finish. It consisted in an avowed consciousness already of the os magna sonitum, "the mouth formed for great utterances," that consciousness resting on a peculiar substratum of personal character that had occasioned a new theory of literature. 'He who would not be frustrate of his hope to write well hereafter, on laudable things ought himself to be a true poet.' was Milton's own memorable expression afterwards of the principle that had taken possession of him from his earliest days; and this principle of moral manliness as the foundation of all excellence, dividing Milton's life into two identity of all literary productions in kind, and their coequality in worth, with the personality in which they have their origin, might have been detected, in more or less definite shape, in all or most of the minor poems. It is a specific form of that general Platonic doctrine of the invincibility of virtue which runs through his Comus.

That a youth and early manhood of such poetical promise should have been succeeded by twenty years of all but incessant prose polemics has been a matter of regret with many. But this
MILTON

491

is to ignore his political and social side. If Burke, whose whole public career consisted in a succession of speeches and pamphlets, is looked back upon as one of the greatest men of his century on their account, why should there be regret over the fact that Milton, after having been the author of Comus and Lycidas, became for a time the prose orator of his earlier and more tumultuous generation? Milton was not only the greatest pamphleteer of his generation—head and shoulders above the rest—but there is no life of that time, not even Cromwell's, in which the history of the great Revolution in its successive phases, so far as the deep underlying ideas and speculations were concerned, may be more intimately and instructively studied than in Milton's. Then, on merely literary grounds, what an interest in those prose remains! Not only of his Areopagitica, admired now so unreservedly because its main doctrine has become axiomatic, but of most of his other pamphlets, even those the doctrine of which is least popular, it may be said confidently that they answer to his own definition of "a good book, by containing somehow "the precious life-blood of a master-spirit." From the entire series there might be a collection of specimens, unequalled anywhere else, of the capabilities of that older, grander and more elaborate English prose of which the Elizabethans and their immediate successors were not ashamed. Nor will readers of Milton's pamphlets continue to accept the hackneyed observation that his genius was destitute of humour. Though his prevailing mood was the severely earnest, there are pages of mirth, and a readiness to laugh at the absurd, and at the same time to sweat for the innocent and laughable irony, reaching sometimes to outrageous farce, and some of them as worthy of the name of humour as anything in Swift. Here, however, we touch on what is the worst feature in some of the prose pamphlets—their measureless ferocity, their boundless licence in personal sacrility.

While it is wrong to regard Milton's middle twenty years of prose polemics as a degradation of his genius, and while the fairer contention might be that the youthful poet of Comus and Lycidas actually promoted himself, and became a more powerful agency in the world and a more interesting object in it for ever, by consenting to lay aside his "singing robes" and spend a portion of his life in great prose oratory, who does not exult in the fact that such a life was rounded off so miraculously at the close by a final stage of compulsory calm, when the "singing robes" could be resumed, and Paradise Lost, Paradise Regained and Samson Agonistes could issue in succession from the blind man's chamber? Of these three poems, and what they reveal of Milton, no need here to speak at length. Paradise Lost is one of the few monumental works of the world, with nothing in modern epic literature comparable to it except the great poem of Dante. This is best perceived by those who penetrate beneath the beauties of the merely terrestrial portion of the story, and who recognize the coherence and the splendour of that vast symbolic phantasmary by which, through the wars in heaven and the subsequent revenge of the expelled archangel, it paints forth the connexion of the whole visible universe of human cognisance and history with the grander, pre-existing and still enveloping world of the eternal and inconceivable. To this great epic Paradise Regained is a sequel, and it ought to be read as such. The legend that Milton here turned epic to the larger is quite incorrect. All that is authentic on the subject is the statement by Edward Phillips that, when it was reported to his uncle that the shorter epic was "generally censured to be much inferior to the other," he "could not hear with patience any such thing." The best critical judgment now confirms Milton's own, and pronounces Paradise Regained to be not only, within the possibilities of its briefer theme, a worthy sequel to Paradise Lost, but also one of the most artistically perfect poems in any language. Finally, the poem in which Milton bade farewell to the Muse, and in which he reverted to the dramatic form, proves that to the very end his right hand had lost none of its power or cunning. Samson Agonistes is the most powerful drama in the English language after the severe Greek model, and it has the additional interest of being so contrived that, without any deviation from the strictly objective incidents of the Biblical story which it enshrines, it is yet the poet's own epistle and his condoned autobiography.

Much light is thrown upon Milton's mind in his later life, and even upon the poems of that period, by his posthumous Latin Treatise of Christian Doctrine. It differs from all his other prose writings of any importance in being cool, abstract and didactic. Professing to be a system of divinity derived directly from the Bible, it contains Milton's metaphysics and of his reasoned opinions on all questions of philosophy, ethics and politics. The general effect is to show that, though he is rightly regarded as the very genius of English Puritanism, its representative poet and idealist, yet he was not a Puritan of what may be called the first wave, or that wave of Calvinistic orthodoxy which broke in upon the absolutism of Charles and Laud, and set the English Revolution agoing. He belonged distinctly to that larger and more persistent wave of Puritanism which, passing on through Independency, and an endless variety of sects, many of them rationalistic and freethinking in the extreme, developed into what has ever since been known as English Liberalism. The treatise makes clear that, while Milton was a most fervid theist and a genuine Christian, believing in the Bible, and valuing the Bible over all the other books in the world, he was at the same time one of the most intrepid of English thinkers and theologians. (D. MA.; X.)

Considerable interest attaches among collectors to the variety of prints representing portraits of Milton. So far as the original engravings or portraits and prints are concerned, which have inspired the large number of engravings, there may be mentioned: (1) The existing Janssen painting, 1618 ("atexit sua e 10"), which belonged to Mrs Milton. (2) An unknown painting of 1623 (?1620), from which was taken an engraving in the Gentleman's Magazine for September 1787 ("atexit sae 12"). (3) The "Onslow" painting of Milton when a Cambridge scholar (lost), which belonged to Mrs Milton and in 1794 was in Lord Onslow's possession; a copy by Van der Gucht was made for Lord Harcourt and is still at Nuneham. (4) A painting of Milton as a boy, which has been given to the poets, and which was engraved by Janssen. (5) The "Bentley's" engraving of Milton from life, at the age of sixty-two, in Milton's History of Britain (1670). (6) Faithorne's original drawing for the above, belonging in 1909 to Sir R. H. Hobart. (7) The Bayfordbury (or Tonson) drawing (probably by Faithorne, or (? by White or Richardson) at Bayfordbury Park near Hertford. (8) A drawing by George Vertue in Dr Williamson's collection. (9) A clay bust (? by Pierce or Simon) at Christ's College. (10) A miniature by Cooper (1653), which is, however, considered by Dr G. C. Williamson not to be Milton at all. (11) A painting by Pieter Van den Plas (d. 1704) in the National Portrait Gallery. (12) An oil painting at Christ's College. (13) The "Woodcock" miniature of Milton when about forty-eight. In Poets' Corner, Westminster Abbey, a bust by Rysbrack was put up in 1737. A monument in St Giles, Cripplegate, by John Bacon, R.A., was erected by Samuel Whitbread in 1793; and a modern statue by Horace Montford also stands there. A memorial window in St Margaret's, Westminster, with an inscription by J. G. Whittier, was presented by G. W. Childs, of Philadelphia.

BIBLIOGRAPHY.—MISS. of the poems of Milton's earlier period in his own handwriting are preserved in the library of Trinity College, Cambridge. These are not enumerated among the gifts made by Sir Henry Newton Pumpkin in 1691, but presumably belonged to him, and came to the library at his death in 1700, as they were found by Charles Mason, a fellow of the college, among papers and books which had been his. They were bound in a folio volume by the care of Thomas Clarke, afterwards Master of the Rolls, in 1736. Besides the poems, with many interlineations and corrections, the volume contains some accounts in some sort of table, for works generally dramatic in form. This manuscript volume, invaluable as an index to Milton's methods of work, was reproduced in facsimile (Cambridge, 1899) by W. Aldis Wright.

The first complete edition of The Poetical Works of Mr John Milton . was printed by Jacob Tonson in 1695. In 1732 Richard Bentley put forward a curious edition of Paradise Lost in which long passages were rejected and placed in the margin on the ground that they were interpolations made possible by Milton's blindness. The Latin and Italian poems, with a translation by William Cowper,
were printed by W. Hayley in 1808. The most important of the numerous later editions of Milton's poetical works are by H. J. Todd (6 vols., 1901); J. Mitford ("Aldine edition," 3 vols., 1832); T. Keightley (2 vols., 1839), who published numerous reproductions of the original "or" Cambridge edition, 3 vols., 1834, of which a new edition appeared in 1890, with memoir, introduction, notes and an essay on Milton's English and versification); John H. C. Dexter (new "Aldine edition," 2 vols., 1901, also in 1894); a reprint retaining the peculiarities of the earlier printed copies, by H. C. Bching ("Oxford edition," 1904); and another, with variant readings, by W. Aldis Wright (Cambridge, 1918). The last two are apparently not yet entirely collected in 1967. They were edited by J. Tolland (3 vols., 1698), by C. Symmons (7 vols., 1866) by Pickering (8 vols., 1851), with the poetical works, and by J. A. St John Hope (2 vols., 1848-1853). There are numerous annotated editions of separate works.

The earliest life of Milton is contained in Wood MS. D. 4 in the Bodleian Library, Oxford, and was printed in the *Experi- menta* of the *Contemporaries of Milton* by E. S. Parsons in Colorado College Studies, No. X (1903). The author, who sympathized with the poet's views, is unknown, but the name of Milton's friend, Dr Nathan Page, is suggested. His account formed the basis of the life given by Anthony Wood in *Fasti oxfordiens* (1691). Wood was also indebted to John Aubrey, whose *Brief Lives* were not printed until later. The life by his nephew Edward Phillips was printed in 1677. A more detailed account was given in *Vita* by William Godwin in his *Lives of E. and J. Phillips* (1815). Samuel Johnson's famous *Life of Milton* (1779), which contains some valuable criticisms, is written from a personal and friendly standpoint. The life of Milton's life, available in the State Papers, were first made use of by H. J. Todd in a third edition (1829) of his *Milton*. All the available information was gathered in Professor Masson's *Life of John Milton* (1912), and in his *Papers: Political and Literary History of His Time* (6 vols., 1859-1880, with index, 1894; new ed., vol. I., 1881) which contains ample reference to original authorities. Shorter works are *Milton and seine Zell* (2 pts., 1807, 1879), by Robert Southey (Milton 1807); by Mark Pattison in the "English Men of Letters" series, and *Life of John Milton* (1860) by Dr Richard Garnett in the "Great Writers" series, with a biographical sketch by J. P. Anderson.

The sources of Paradise Lost have given rise to much discussion. It has been supposed to owe something to Adamo, a comedy by Giovanni Battista Andreini (1578-1652), to the *Paraphrase* associated with W. J. E. Milnes, which was printed at Oxford in 1655 by Francis junius, and to the *Lucifer* and other plays of Joost van den Vondel. Parallelisms between Vondel and Milton were pointed out by Mr Edmund Gosse in *Literatures of Northern Europe* (1879), and the comparison was carried further in Mr G. Edmundson's *Milton's Milton; A Curiosity of Literature* (1885), a book which aroused much discussion. A valuable contribution to Miltonic criticism was made in 1893 by Mr Robert Bridges in an essay on *Milton's Prosody*. This was reprinted in 1901, with some additional matter and an essay on "Classical metres in English Verse" by W. J. Stone. Amongst other critical essays should be mentioned *Milton and Shakespeare* (Edinburgh, 1875); Walter Baggehot (Literary Studies, vol. 1., 1879); S. T. Cokeridge (Seven Lectures on Shakespeare and Milton 1856); Edward Dowden (Transcripts and Studies on English Poetry); Schorer (Études sur la littérature con- temporain, vol. vi., 1882; Augustin Birrell (Obiter dicta, second series 1887); Walter Raleigh (Milton, 1900); E. Allodioli, *Giovanni Milton e l'Italia* (Prato, 1907).

Cromwell's lists of Milton's poetical works were compiled by G. L. Prendergast (Madrass, 1856-1876); by C. J. Clevelend (1857), based on a verbal index used in an American edition 1853, of the poetical works; by John Bradshaw (1854), by L. L. Lockwood, *Lectures on the English Poetical Works of John Milton* (New York, 1907).

The tercentenary of Milton's birth was celebrated in 1868 in Cambridge, London and elsewhere. An exhibition of the portraits of Milton, books and autograph manuscripts, with a collection of all printed editions of the poet's works, was held in June and July at Christ's College, Cambridge. The catalogue of this exhibition, drawn up by Dr G. C. Williamson, forms a valuable bibliographical and iconographical of the poet. A collection of portraits of the poet and early copies of his works was also held in December at the British Museum, and the anniversary itself was celebrated by a special meeting at which papers by Professors W. J. Courthope, Edward Dowden and others were read. There was a religious service at St Mary-le-Bow, Cheapside, and a banquet at the Mansion House.

MILTON, a town of N.E. Norfolk county, Massachusetts, U.S.A., about 7 m. S. of Boston, the Neponset river forming a large part of its N. and N.W. boundary. Pop. (1890), 4765; (1900), 6578 (1840 being foreign-born); (1905, state census, 7054; (1910, U.S. census, 7461). The town is served by the New York, New Haven and Hartford railway, and is primarily a residential suburb of Boston, with which it is connected by electric lines. The township covers an area of about 13 sq. m., and includes the villages of Milton, East Milton and Mattapan. The country is rolling and hilly, the Blue Hills (with the exception of a part included in Braintree in 1712 and now in Quincy) lying in Milton. On Great Blue Hill, the highest (635 ft. above tide-level), great fires were kindled at the news of the repeal of the Stamp Act, of the adoption of the Declaration of Independence, and of the surrender of Burgoyne and Cornwallis; beacon fires were burned during the American War of Independence for torches was built at an early date; and in 1835 the Blue Hill Observatory for meteorological investigation was established by Abbott Lawrence Rotch (b. 1861), who made important investigations concerning clouds, and attracted attention by his use of kites for obtaining meteorological data. Milton Academy (a non-sectarian school) was founded in 1798, opened in 1805, and suspended in 1807; a new academy was opened in 1885. There is a public library, which was opened in 1871, and in 1909 had more than 20,000 volumes. Cunningham Park is under the control of the trustees of a fund left for the benefit of the township, and contains a gymnasium, skating-pond, tennis courts, &c., open to townsmen only. Hutchinson Field, another public park, is a part of the estate of the last royal governor, Thomas Hutchinson; Governor Jonathan Belcher also lived in Milton for a time. There are two granite quarries in the township immediately north-west of the Blue Hills; the granite is of the "dark quality" variety—dark bluish grey in colour—and is used chiefly for monuments. Milton, originally a part of Dorchester, was first settled in 1649, and was called Uncatassa- quissit. The township was separated from Dorchester and incorporated in 1662. It owes its name either to its early English inhabitants, or to the manufacture of grind and grist mills (Milton being abbreviated from Milltown) or to Milton Abbey, Dorset, whence members of the Tucker family came, it is supposed, to Milton about 1662. In 1712 the Blue Hill lands were divided between Milton and Braintree, and in 1868 part of Milton was included in the new township of Hyde Park. In Milton, on the 9th of September 1774, at the house of Daniel Vose, a meeting, adjourned from Dedham, passed the bold "Suffolk Resolves" (Milton then being included in Suffolk county), which declared that a sovereign who breaks his compact with his subjects forfeits their allegiance, that parliament's repressive measures were unconstitutional, that tax-collectors should not pay over money to the royal treasury, that the towns should choose militia officers from the patriot party, that they would obey the Continental Congress and that they favoured a Provincial Congress, and that would seize crown officers as hostages for any political prisoners arrested by the governor; and recommended that all persons in the colony should abstain from lawsiness.

MILTON, a borough of Northumberland county, Pennsylvania, U.S.A., on the Susquehanna river at the mouth of Lime- stone Run, about 66 m. N. of Harrisburg. Pop. (1890), 5317; (1900), 6175 (166 foreign-born); (1910), 7450. It is served by the Pennsylvania, and the Philadelphia & Reading railways, and is connected with Lewisburg and Watsontown by an electric line. Milton has an attractive public park, is in an agricultural region, and has various manufactures. It was founded in 1792, and incorporated as a borough in 1817. In 1880 it was in great part destroyed by fire.

MILWAUKEE, a city and the county-seat of Milwaukee county, Wisconsin, U.S.A., the largest city of the state, at the mouth of the Milwaukee river on the W. shore of Lake Michigan, about 85 m. N. of Chicago. Pop. (1900), 285,315; (1910), 373,877. The Milwaukee river entering the city from the north is joined about 1/2 m. from its mouth by the Menominee flowing from the west and a short distance from the lake by the Kinnikinic flowing from the south. These rivers are navigable for lake traffic into the heart of the city. Milwaukee Bay, into which their combined waters empty, is an inlet of Lake Michigan across the harbor, an expanse of deep water. The construction of extensive piers and breakwaters a fine harbour of refuge has been created; and its inner harbour is deep enough for the largest lake-steamers.
MILWAUKEE

From the shore of the lake the land rises, rather abruptly in most places, to a height of from 75 to 100 ft. From a broad plateau overlooking the lake the land slopes gradually westward to the river, again rising on the north, west and south to a height of 125 ft. or more. The rivers separate the city into distinctly marked divisions of varying character known as the east, west and south sides. The manufactories are largely on the "flats" along the rivers and on the south side. The extensive use as building material of cream-coloured brick made in the vicinity gives the city its nickname, "the Cream City."
The city has many beautiful parks and squares, the most picturesque of which is Juneau Park, along the lake bluff. It contains the statues of self Erichson and Solomon Juneau. Other parks are Lake Park, also on the lake shore, at North Point, where stands the waterworks pumping station, built in 1872; Riverside and Kilbourn Parks, east and west respectively of the upper Milwaukee river, in the northern part of the city, Washington Park on the west side, containing a menagerie and a herd of deer; Sherman Park on the west side, and Kosciusko, Humboldt and Mitchell Parks on the south side. McKinley Park on the lake shore south of the city, and Whitefish Bay 6 m. north of the city, are popular bathing resorts. In addition to the statues in Juneau Park, there is the statue of Kosciusko in the park of that name; one of Washington and a soldiers' monument on Grand Avenue; a statue of Henry Bergh in front of the city hall; one of Robert Burns in the First Ward Park, and, in Washington Park, a replica of Ernst Rietschel's Schiller-Goethe monument in Jena, given to the city in 1908 by the Germans of Milwaukee. Of the several cemeteries, that of Forest Home, south-west of the city, is the largest and most beautiful. The city is well sewered, and has an excellent water-supply system owned by the municipal and representing an investment of more than $5,000,000. The water is obtained in Lake Michigan through an intake far out in the lake. Through a tunnel 4½ miles long, constructed in 1888, water is pumped by means of one of the largest single pumps in the world from the lake into the upper Milwaukee river, which is thus completely flushed by fresh water every twenty-four hours.

Milwaukee is one of the most healthful of the larger cities of the United States. Its average annual death-rate for 1900-1904 was 13.6. The proximity of Lake Michigan cools the atmosphere in summer and tempers the cold in winter. As a result, the extremes of heat and cold are not as great as those in most inland localities. The mean temperatures vary between 20° in January and 70° in July, with extremes of 100° and −25°. The mean annual precipitation is 34.4 in.

Suburbs.—Milwaukee proper occupies 221 sq. m., a small area as compared with other cities near it in population—Detroit (56 sq. m.) and Washington, D.C. (691 sq. m.). As a result, the population has overflowed into several populous suburbs industrially a part of the city proper, and local headquarters for the limited mosques. They are the township of Wauwatosa (pop., 1905, 11,132; 1910, 11,536), and the city of the same name, separated from the township in 1897 and having in 1910 a population of 3336; the city and township on the Menomonee river, immediately adjoining the city on the west. The first settlement was made here in 1838. Wauwatosa has important manufactures, including machinery, brick, lime, beer, chemicals and wooden-ware, and extensive market gardens and nurseries and valuable grounds. Carnarvon Park, with an area of 150 acres, and is the seat of an Evangelical Lutheran theological seminary (1863), of Lutheran homes for the aged and orphaned, of the Milwaukee county hospital for the insane, of the Milwaukee sanatorium, of the nervous diseases, and of the north-western branch of the national soldiers' home, which has grounds covering 385 acres and with main buildings and barracks affording quarters for over 2000 disabled veterans, and has a hospital, a theatre, and a library of 15,000 volumes. Within the limits of Wauwatosa also are the State Fair grounds. Other suburbs are West Allis (pop., 1905, 2306; U. S. census, 1900, 2469), an incorporated rapidly growing manufacturing city on the west; Cudahy (pop., 1905, 6578), an incorporated village south of Milwaukee, largely devoted to meat packing; South Milwaukee (pop., 1910, 6092), an incorporated city with several important manufactories at North Milwaukee (pop., 1910, 1860), a village immediately adjoining the city on the north.

Public Buildings, Institutions, &c.—The principal public building in the city is the Federal building (1895–1898), the post office, customhouses and local headquarters for the limited mosques. The public library and museum, on the north side of Grand Avenue, in addition to an excellent collection of natural history, paleontology, &c., contained in 1909 a library of about 100,000 volumes. The chamber of commerce, and the Pabst, Mitchell, North-Western Life, and Milwaukee Bank associations, are among the principal business institutions. In Milwaukee are St John's Roman Catholic Cathedral and All Saints Protestant Episcopal Cathedral: both are the see of a Roman Catholic archbishop (established in 1892) and of a Protestant Episcopal bishop. Among other church structures are Plymouth Congregational Church, Westminister Presbyterian, Church of Gesu (Roman Catholic) and Trinity Lutheran church, on the east side, and the Plankinton, the Republican and the Schiller church on the west. Among the theatres are the Davidson, Majestic, Schubert, and the National and the Pabst German. During the summer there are open-air theatres in the city. The social clubs include the Milwaukee, Deutscher-Concordia, University and Marquette clubs. The predominance of German influence in the city is evidenced by at least 25 Lutheran churches and numerous Turnverein societies. There are 12 hospitals (3 of them university institutions), 6 orphan asylums, 4 homes for the aged, a foundlings' home, a state industrial school for girls.

Transportation.—Milwaukee is favourably situated commercially, with excellent facilities for shipping both by lake and rail afforded by four trunk lines and a dozen lines of lake steamboats. It is served by the Chicago & North-Western, the Chicago, Milwaukee & St Paul & St Pauls' lines, the Milwaukee & St Paul, and the Grand Trunk, and the Père Marquette railways. The last-named connects with the main line at Ludington, Michigan, by means of a railway ferry across Lake Michigan; the Grand Trunk has a railway ferry from Lake Michigan to Grand Haven. The lake steamboats, which connect with the interurban electric lines leading to Waukesha, Oconomowoc and Watertown on the west, Sheboygan and Fond du Lac on the north, and Chicago and intermediate points along the lake shore on the south.

Trade and Commerce.—Commercially Milwaukee is one of the most important of the inland cities of the United States, although its trade is largely domestic. It is a distributing point for a considerable part of Wisconsin, and several states farther west, its wholesale business aggregating about $350,000,000 annually. The Milwaukee produce sold in Milwaukee averages about $75,000,000 per year. The chief commodities of trade are coal, grain, lumber, fish and various products of the city's own manufactories. Milwaukee is an important grain shipping port—1908 it shipped 28,618,519 bushels of grain and 3,752,033 barrels of flour, and its share of the grain trade is considerable. Milwaukee is also one of the largest distributing centres in the country for coal, which is received by lake, and stored in enormous coal docks for transhipment by rail throughout the west and north-west. The city is a port of entry, and customs duties were valued at $3,990,437, and its exports at only $75,525.

Manufactures.—In 1905 the total value of Milwaukee's factory products was $136,881,545, or 12.5% more than in 1900. In the manufacture of malt Milwaukee is one of the leading cities of the United States and of the world. The total value of these products for 1905 was $20,990,245, of which $22,134,580 was the value of malt liquors and $3,773,665 was the value of malt. In 1895 the total value of malt produced in Milwaukee was $2,085,760. Milwaukee is one of the largest beer-manufacturing centres in the state and 7.4% of the entire product of the United States. Other products exceeding $1,000,000 in value were leather ($8,174,507), Milwaukee being second in the manufacture of leather among the cities of the United States; foundry and machine
shop products ($10,572,273); iron and steel ($7,010,793); flour and grist-mill products ($6,320,428); slaughtering and meat-packing products ($5,958,315); men's clothing ($4,759,548); boots and shoes ($3,529,405); electrical machinery, apparatus and appliances ($2,039,164); and cigars and cigarettes ($1,540,019); furniture ($1,167,290); trunks and valises ($1,623,310); hosiery and knit goods ($1,935,176); confectionery ($1,977,230); and soft drinks ($1,337,633). Among Milwaukee's largest industrial establishments are the Schlitz Brewing Company for the manufacture of beer; the collection of the city, the machine shops (35 acres) of the Allis-Chalmers Company at West Allis, employing about 5000 men and making engines of all kinds; and the plant of the Illinois Steel Company, which has a capital of $65,000,000. The flour mills of Milwaukee have a capacity of about 12,000 barrels a day. Two of the city's tanneries are among the largest in America. In the Menominee river valley the peculiar cream-colored Milwaukee bricks are made. North of the city on the Milwaukee river are extensive cement works.

Newspapers.—The first newspaper in Milwaukee, the Advertiser, began publication in 1818. The first German newspaper was established in 1834. In 1909 there were eleven daily newspapers, as follows: Evening Wisconsin (1874; Republican), Free Press (1901; Independent Democrat), Journal (1882; Independent Democrat), News (1886; Independent), and Sentinel (1857; Republican), the oldest paper in continuous publication, Daily Commercial Letter (Commercial), Reporter (legal and commercial), D'Alton's Weekly, Italia (1888; Republican; Polish), Germania Abendpost (1872; Independent; German); and Der Herald (1854; Independent; German). Of more than a hundred other publications, few, if any, were weekly publications, were published in German. There are 5 Polish weekly publications, 3 Bohemian, 1 Italian and one periodical for the blind.

Population.—The population of Milwaukee in 1840 was only 1712. During the following decade there was a steady flow of immigrants from the eastern states and from Europe, with the result that by 1850, two years after the admission of Wisconsin to the Union, the population was 20,691. The population at the succeeding decennial censuses was as follows: (1860), 45,246; (1870), 71,440; (1880), 115,587; (1890), 204,468; (1900), 283,315. In 1905, according to the census, the population was 321,948. The fact that out of a population of 283,315 in 1900, 88,591 were foreign-born, and 235,880 were of foreign parentage, that 53,854 were born in Germany, that 124,211 had both parents born in Germany, and that 26,834 additional had one or the other parent foreign, stamps the character of Milwaukee's population. The negro population in 1900 was only 862. The proportion of illiterates is small. Of the male population, aged 10 years or more, only 326 (208 foreign-born whites; 144 native-born whites) were illiterate in 1900.

Government.—Milwaukee is governed under a city charter of 1874, providing for the city government most common in America, a mayor (elected biennially) and a single board of aldermen. There are the usual administrating boards whose members are appointed by the mayor, some of them with the approval of the board of aldermen, though the board of school directors is elected by direct popular vote. Two boards of civil service commissioners, one for fire and police departments and one for all other departments, have supervision over the city's civil service.

The assessed valuation of taxable property, in the city, in August 1906 was $201,585,127, of which $157,011,560 represented realty and $44,573,567 personalty. The valuation is about 60% of the actual value. The tax rate for all purposes in that year was $2.26 per $100. According to a special report of the census the cost of the government of Milwaukee in 1906 was smaller per capita than that of any other city in the country with a population of over 300,000. At the close of the year 1906 the total debt was $8,835,049, and the funded debt was $8,166,590.

History.—The first Europeans known to have visited the site of Milwaukee were Father Jacques Marquette, the Jesuit missionary, and his companion, Louis Joliet, who on their return in the autumn of 1673 to the mission of St Francis Xavier at Detroit, from a trip down the Mississippi, skirted the west shore of Lake Michigan in their Chippewa canoes. Milwaukee Bay is distinctly marked in the map attributed to Marquette, the original of which is now in the Jesuit College at Montreal, Canada; it was discovered in a convent in Montreal by Felix Martin (1804—1886), of the Society of Jesus, and was copied by Parkman. In 1679 La Salle and his party probably stopped here on their way south, and in the Jesuit Relations of that year the name Milwaukee first appears, as "Mililaco." This, and the various other spellings of the name, attempted to reproduce the Indian name of the village here, which Kelton thinks was pronounced Minewagi and meant "there is a good point," or "there is a point where buckthorn berries grow," in allusion to the fertile soil. Doubtless at this time began to frequent the Wisconsin forests, touched at the bay many times within the succeeding years as the place was known to be a favourite rendezvous of the Fox (or Outagamie) Indians. In 1699—1700 Father St Cosme, a Recollect friar, was here, finding bands of Mascoutens, Fox, Winnebago and Potawatomi. He called the river "Milwark," "Melvarick" and "Miilwark." For more than half a century no definite reference to the place can be found. In 1760 its advantageous situation attracted the English trader, Alexander Henry, the first Englishman known to have visited the spot. Three years later there was a French fur-trading post here, but it is uncertain just when it was established or how long it was maintained. In 1795 Jacques Vieu, a Frenchman in the employ of the North-Western Fur Company, established a permanent post here, which seems to have continued, under his direction, with practically no interruption until 1826, when it was superseded by that of Astor's American Fur Company. Vieu built a dwelling and a warehouse and conducted extensive trading operations. In 1818 he disposed of the settlement to a young Frenchman named Laurent Solomon Juneau (1793—1856), who married one of Vieu's daughters and eventually bought out his business. Juneau and several others who arrived at about the same time built homes on the east side of the river near the foot of the present Wisconsin Street. Vieu's house and store was at this time on the south side. Milwaukee was on the direct route of travel between Fort Dearborn (Chicago) and the flourishing settlement at Green Bay, and at once after the treaties between the United States and the Menominee in 1831 and 1833 for the extinguishing of the Indian titles, settlers began to come to the neighbourhood. A map of 1829 shows a small settlement on "Milwaukie Bay," and the treaty of the 8th of February 1837 speaks of the "Milwaukie or Manawaukie River." Morgan L. Martin (1805—1887) of Green Bay, a lawyer and judge, and a delegate to Congress in 1835—1837 from Wisconsin territory, explored the harbour facilities in 1833 and made a map of the place which he called "Milwaukie." He entered into an agreement later in the same year with Juneau and Michael Dousman for its development. A saw-mill was built in 1834, and settlers began to arrive. The east side was platted in the summer of 1835, and very soon afterward the plat of a settlement on the west side was also recorded, Byron Kilbourn being the chief projector and proprietor of the latter. The rival settlements, officially known as Milwaukee East Side and Milwaukee West Side, bore the popular designations of "Junecatown" and "Kilbourn town." A third settlement, begun on the south side by George H. Walker and known as "Walker's Point," was subsequently platted independently. The rivalry between the east and west sides towns was intense, the plats were so surveyed that the streets did not meet at the river, and there were bitter quarrels over the building of bridges. Milwaukee county was set off from Brown county in 1834, and in 1836 the establishment of the town was authorized. Under this act the east and west sides were independently incorporated in February 1837. A realization that the continuation of independent and rival corporations retarded growth eventually led to a compromise by which the two were united as two wards of the same village in 1839, the autonomy of each being still recognized by an odd arrangement whereby each maintained practically independent management of its finances and affairs. Walker's Point, the south side, was annexed as a third ward in 1845, and in 1846 the three wards were incorporated as the city of Milwaukee, of which Solomon Juneau was elected first.
MIMETITE—MIMICRY

495

mayor. The influence of this early rivalry may be seen in several provisions of the existing city charter.

About 1840 a strong tide of immigration from Germany set in, continuing steadily for a half-century. It was greatly accelerated by the German revolutionary movements of the late forties, which added to the city's population a considerable element of educated Germans of the upper class. From this time the Teutonic character of the population was marked. The first newspaper, the Advertiser, began publication in 1836; the first bank was established in 1837. In 1839 George Smith and Alexander Mitchell established the Fire and Marine Insurance Company, a "fire and marine" this "fire" was known for forty years as one of the strongest banking houses west of the Alleghenies, it notes passing at par during panics in which even the government issues were depreciated. Through it the Chicago Milwaukee & St Paul and other western railways were financed. Beer was first brewed in Milwaukee in 1840. Milwaukee was connected with Chicago by telegraph in 1849, and by railroad in 1856. Previous to this, however, in 1851, the first train ran over the Chicago Milwaukee & St Paul railway to Waukesha, and in 1857 through trains were run over the same line to Wisconsin City.

MIMETITE, a mineral consisting of lead chloro-arsenate, (PbCl)Pb4(AsO4)3, crystallizing in the hexagonal system and closely resembling pyromorphite (CuS) in appearance and general characters. The arsenic is usually partly replaced by equivalent amounts of phosphorus, and there may thus be a gradual passage from mimetite to pyromorphite. The two species can, as a rule, only be distinguished by chemical analysis, and because of their close resemblance the less frequently occurring chloro-arsenate was named mimetite or mimetisite, from Gr. μιμητις, imitator. Crystals of pyromorphite though usually optically uniaxial are sometimes biaxial, but in mimetite this anomalous character is almost always present; a cross-section of a hexagonal prism of mimetite shows a division into six optically biaxial sectors or a complex lamellated structure. In colour mimetite is usually yellow or brown, rarely white or colourless; the luster is submetallic to adamantine. The hardness is 3½, and the specific gravity 7.0-7.25. Like pyromorphite, mimetite is found in the upper parts of veins of lead ore, where it has been formed by the oxidation of galena and mispickel. When found in large amount it is of importance as an ore of lead.

The best crystallized specimens are those from Johanngeorgenstadt in Saxony and Wheel Unity in Cornwall. It was formerly found in considerable amount at Dry Gill in Cumberland, as six-sided barrel-shaped crystals of a brownish-red or orange-yellow colour and containing a considerable proportion of phosphoric acid; this variety has been called campylite, from Gr. καμπύλος, curved, on account of the remarkable curvature of the faces of the crystals.

MIMICRY, in zoology, the deceptive and advantageous resemblance presented by defenceless and edible species of animals to other species of animals living in the same locality, which are harmful or distasteful and are consequently avoided by all or by a majority of the enemies of the class to which the mimetic and usually the mimicked species belong. Mimicry is a special form of protective resemblance, differing from ordinary protective resemblance only in being recognized by the similarity of the object to a piece of bark or of leaf and stick-insects to the objects after which they are named, in that the imitated object belongs to the animal kingdom and not to the vegetable kingdom or to inorganic nature. Although, like protective resemblance, quite independent of affinity between the organisms concerned in the likeness, mimicry occurs most commonly between animals structurally similar, and therefore related, to one another, the relationship may be close or remote. For instance, the commonest and best-known cases are found in insects where both mimic and model may belong to the same genus, sub-family, family or order, or to different orders. More rarely it occurs between members of distinct classes of the same sub-kingdom, i.e., between spiders and ants or spiders and snails. But in no case does it appear that the modifications in shape and colour, which contribute to bring about a mimetic resemblance, are greater and more elaborate than those which result in the simpler examples of ordinary protective resemblance.

The principle of protective resemblance, for which the term mimicry, as above defined, was originally employed, was first explained by H. W. Bates. Subsequently the meaning of the word was extended by F. Müller to include cases of mutual resemblance between two or more noxious species inhabiting the same area. Hence the resemblances belonging to the first category are commonly termed " Batesian mimicry," and those belonging to the second category " Müllerian mimicry," or more properly the " Müllerian resemblance.

The difference between the two phenomena is essential and evident, but without attempting a mental information as to palatability it is impossible to know with certainty to which of the two a particular case of mimicry is to be assigned. Over and over again extended knowledge on this point and inferences drawn from other facts have shown the certainty or probability of examples of mimicry being in reality " Müllerian," which were previously accepted without question as " Batesian." A simple illustration will serve to explain these two aspects of mimicry and to show the advantage in the struggle for existence that mimicry confers upon the species concerned.

There is a common English Syrphid fly (Eristalis tenax) known as the drone-fly from its resemblance to a large hive or honey bee. Honey bees are protected from a large number of insect enemies because they sting and are distasteful. Insect-eating birds soon learn to associate distastefulness with the size, form and colour of the bees, and consequently leave them alone after one or more trials. But flies of the drone-fly kind cannot sting, and, so far as is known, are perfectly innocuous and edible. The advantage to the fly of its deceptive resemblance to the bee is theoretically perfectly evident and practical can be demonstrated by experiment. It is in the first place a matter of common knowledge that human beings who have been taught to avoid handling bees invariably fear to touch drone-flies, unless specially trained to distinguish the one from the other. Moreover, Professor Lloyd Morgan found that young birds that had tasted and rejected workers of the hive bee as unpalatable subsequently refused to taste not only drones, which have no sting, but also drone-flies. So far as our information at present extends the resemblance between these two insects is a simple case of mimicry in the Batesian sense of the word. That is to say, an edible species is protected by resembling one that is inedible. But if it be discovered, as is possible, that the drone-fly is also inedible, the mimicry must be ascribed to the Müllerian category, and the reason for it becomes less evident. In what way, it may be asked, are two or more distasteful species of insects, occurring in the same locality, benefited by resembling each other? The ingenious explanation suggested by Fritz Müller for similar cases met with in butterflies is probably the true answer. This explanation depends upon what is now an experimentally demonstrated fact that insectivorous birds, and probably other animals, have no instinctive knowledge of what insects are edible and what are inedible. This knowledge is acquired by experience, and since it is not, at all events as a rule, taught by the first taste to any individual bird, it is reasonable to infer that a considerable amount of injury, sufficient to disable if not to kill, is annually inflicted upon insects belonging to species protected by distastefulness or kindred qualities. Now insects that possess noxious attributes, and the same is true of other animals, usually have a conspicuous warning coloration which appeals to the eyes of enemies and helps them to remember more easily the cause of an
unpleasant experience, helps in fact to establish a psychological association between a particular style of coloration and a nasty taste or a painful wound. This being so, it is evident that if all the distasteful species in a given area are differently coloured, some individuals of all the species will be annually tasted and thus be protected in the experimental tasting of insects by those before the numerous species of the fruitfly. But if all the species in question resemble each other the resemblance will be mutually beneficial to them because the association between the two attributes they have in common, namely distastefulness and a particular scheme of colour, will be rapidly established. One lesson only, instead of many, has to be learnt; and once learnt at the expense of a few individuals of one or two species it will thereafter be applied indiscriminately to all. This type of mimicry has been well defined by Professor E. B. Poulton as the unification of warning colours.

Since belief in the adequacy of the two theories, above outlined, to account for the facts they profess to explain, depends ultimately upon the testimony that can be brought forward of the usefulness of warning characters, of the deception of mimicry and of the selective learning by experience possessed by enemies, it is necessary to give some of the evidence that has been accumulated on these points.

(1) In South America there are butterflies formerly grouped as Heliconidae with companions of the genera of the Heliconia and slender butterflies, which are abundant in individuals so as to be susceptible of easy capture. They possess scent glands. By observation and experiment it was discovered independently by Messrs. Bates and Wallace and Bell that these butterflies by birds would be captured by them, and therefore, prey upon unprotected Lepidoptera. (2) As the result of a series of trials made in Calcutta F. Finn came to the conclusion that young birds had no knowledge of the unpalatability of many tropical insects, but that experimental tasting soon teaches them to recognize and avoid species they have previously rejected with dislike, and that having once learnt the lesson they long remember it. (3) That birds may also be deceived by insects that mimic those they have found to be unpalatable has been shown by the above-quoted experiment with the drone-fly and the honey-bees made by Professor Lloyd Morgan. He also found that the children of the Pigeon-rumped Vulturine, who are said to remove the wings of harmless insects but possess none of their colours, are placed upon glass slips banded black and yellow, afterwards refused to touch meal moistened with water and spread upon the same slips, although they had previously eaten it with readiness off plain coloured slips. With two exceptions, these children that had learnt to associate black and yellow banding with a bitter taste also refused to touch the caterpillar of the cinnabar moth (Euchloe jasobae), which is banded with these colours. Moreover, young birds that had been taught by experience that these caterpillars are unpalatable also learnt wings untouched. (4) Guy Marshall once offered to a baboon a distasteful unpalatable uncoloured insect in such a way as to display its bright red and black markings to the monkey. It was taken but rejected after being tasted. A specimen of another butterfly (Pectiessa semara) which mimics the Arraca was then offered it, and the baboon seized it, held it for a few moments, and then let it escape uninjured without trying to taste it. But when another butterfly of the same species, but with the wings cut off, was offered to it it was eagerly accepted without dislike. The results of this experiment with the baboon and with those of the birds are precisely what would be expected if the theory of mimicry is true. Experiments to test distastefulness have also been made with various kinds of inedible, unpalatable Arthropoda, like spiders and mantises. These experiments have shown that Arthropods also have their likes and dislikes in the matter of insect-food and frequently refuse to eat insects which are warningly coloured and are distasteful to vertebrate enemies.

They appear, however, to have no appreciation of mimetic and warning colours, and have therefore not influenced in any way the evolution of mimicry and resemblance described here. Nevertheless, as explained below, it seems to be highly probable that anti-mimicking insects and spiders, when the resemblance is dependent on a greater extent upon size, shape and movement than upon tint, have acquired their mimetic likeness essentially to protect them from the attacks of such insect-enemies as predacious wasps of the family Pompilidae, flies of the family Asilidae, and from social predators of the family Ichneumonidae, as well as from other insect eating Arthropoda.

The term mimicry has also been applied to resemblances of a different kind from the two enumerated above—resemblances, that is to say, by which predaceous species are supposed to be enabled to approach or mix without detection with animals they prey upon or victimize in other ways. To this end the resemblance may be actually to the species victimized or preyed upon or else to a species which the species preyed upon resembles. This phenomenon is termed "aggressive mimicry" as opposed to the Batesian and Mullerian phenomena, which are termed "protective mimicry." A few possible cases of aggressive mimicry are enumerated below. The following cases of mimicry in different classes of the animal kingdom; but the phenomenon is of comparatively rare occurrence, and the supposed instances may be susceptible of other interpretations, excluding them altogether from mimicry, or bringing them under the Batesian or Mullerian interpretation of the phenomenon.

Among ammals there are no examples of mimicry known. It has been claimed that the resemblance between some of the birds of the gnatcatcher (Lyre-birds) and the Psophia of South America, both in form and colour, is the category of aggressive mimicry, the tupaias being enabled by their likeness to approach and pursue upon small birds or other animals for which they hunt, with comparative ease to get out of the way. But this hypothesis cannot be accepted as furnishing a satisfactory explanation of the likeness. For in the first place there seems to be no good reason for thinking that the Tupaias are led to any considerable extent upon the birds of this kind, and in the second place the resemblance is due to characters which may be merely adaptations to a similar mode of life. A long and bushy tail, for instance, is a useful balance and is a not uncommon feature in mammals which lead an active arboreal life. Similarly the dull coloration of the two sets of animals is very possibly procrastic and serves to hide both shrews and squirrels from dangerous enemies. It is not improbable that the Tupaias, in taking advantage of a degree of likeness in question as due to similarity in habitat and not as mimetic.

In East and South Africa there is a genus of Mustelidæ known as Idionyx (Zerilia) which possesses a foetid odour and is warningly coloured. In the same manner as the Psophia it has been claimed by Lloyd Morgan that several larger insectivorous mammals, including the mongoose (Herpestes), the weasel, and various other species, have been driven away by the mere presence of Idionyx through the use of their similar odor. There also occurs in South Africa another member of this family (Poecilogale albinucha), which is very similarly coloured. It is possible that this resemblance is mimetic in the Batesian sense of the word, and that the Poecilogale is so driven off by its likeness to the highly offensive and warningly coloured Idionyx. But, on the other hand, Poecilogale may itself be a protected form since sub-saharian rodents are commonly found in the company of vipers of the same tribe. If this be the case the two species probably furnish an instance of true Mullerian mimicry.

In South America there is considerable superficial resemblance between the little bush dog (Cerchneis subbuleo) and the Ichneumonidae, which is an arachnoid animal of the same countries—the tayra (Galera barbara). The tayra is, when adult, black beneath and on the legs, and not uncommonly has a considerable quantity of greyish hair on the head. In these particulars, as well as in size and shortness of leg, the dog resembles the weasel; and since there are good reasons for believing that the latter is protected alike by ferocity and stink-glands, it is quite possible that the dog, of unusual coloration and form for the Canidae, is protected from the attacks of pumas, jaguars and ocelots by his likeness to the tayra.

A few cases of mimicry have been recorded in birds. The common cuckoo (Cuculus canorus) is found in most parts of Africa and Asia, and closely resemble sparrow-hawks. Some cuckoos are singular for their habit of using the nests of smaller birds to lay their eggs in, so that the young cuckoos are reared upon the backs of their foster-parents, which has been supposed to be the object of the likeness exhibited to the hawk. It is possible that the cock cuckoo either to frighten the small birds away from their nests or to lure them in pursuit of him, while the hen bird quietly introduce her egg into the nest, as the most obvious explanation. The sexes of the cuckoo resemble the hawk does not necessarily prove this suggested explanation to be false; but if it be true that the smaller passerine birds are duped by the similarity to the bird of prey, it may be that the cuckoos themselves escape molestation from larger hawks on account of their resemblance to the sparrow-hawk. Another species of this group, the black cuckoo of India, apparently mimics the black drongo-shrike (Dicrurus ater), the resemblance between the two species being very close. The drongo is a fierce and powerful bird which will not tolerate a strange bird of the size of a cuckoo near its nest, yet on account of its resemblance to the cuckoo, the latter is often observed to lay her egg in the nest of the drongo, which mistakes the cuckoo for one of its own kind. In this case also both sexes of the cuckoo mimic the drongo, whereas according to the theory it would be expected that the male should imitate the drongo. The resemblance to the pugnacious drongo may be beneficial in protecting the defenceless cuckoo from enemies.

Several observations, however, by C. Marshall on the inediability of certain birds suggest that the resemblance between cuckoos and hawks on the one hand and cuckoos and drongos on the other may be susceptible of another explanation in full agreement with the theory of mimetic and resemblance. By Bird, and the South African drongo (Dicrurus (Buchanga) assimilis) was rejected after one or two attempts to eat it by a hungry mongoose (Herpestes galera) which had been starved for purposes of the experiment. But more than this, the mongoose, which is blue black, refused to eat the same.
Insects of the order Orthoptera, departure from the normal in form and coloration to which it is similar to other living things, usually takes the line of protective resemblance to parts of plants. This is well exemplified by the leaf-insects (Phyllium) and stick-insects (Blastra), where the likeness to the models after which they are named is almost perfect. The collector is likely to lose many of the sub-globular-like of the abdomen of the ant. This insect comes from Central America. Still more curious is the mimicry of another of these insects from Venezuela which is found in company with stick-insects (Heteropterus). The ants, pursuing their operations of leaf-storage, these ants present the appearance of a crawling crowd of leaf-particles, fragments of leaves being carried by the insects in such a way as to conceal a great deal. In this group the whole structure, from the red, black, and dark colored legs beyond the burden. The immature form of the above-mentioned species of Membracidae mimics both ant
and leaf-particle. The legs and lower part of the body are dark coloured, but the dorsal surface of the thorax and abdomen is coloured green and is raised so as to correspond with the irregular margin of a fragment of leaf cut out by the mandibles of the ant. In Bommeo the Homopteran Issus bruchoides mimics a species of Curculionid beetle of the genus Alis (C. myodon) offers a striking and detailed resemblance to the head of a snake (Dendrophis picta).

In the second order are sometimes confined to the larval stage. The early larval stage of the "Lobster Moth" (Stauroips lagis), for example, presents a general resemblance, due to a combination of certain features. The dark grey wholly head and caudal disk with its two tentacles representing respectively the abdomen and antena-bearing head of the model. A parallel case of mimicry exists at Singapore between the larva of a butterfly and a larva of the cobra (Ophryxara serra-ga). In this case also the posterior end of the larva represents the anterior end of the ant. Another instance of mimicry affecting the larval form is supplied by the moth Eudromia virens (the caterpillar of the red triangle) which mimics a certain species of saw-flies. The resemblance that certain moths—e.g. Trochilium apiiforme, crenatiforme—present to bees and wasps is effected in the instance of a species (flies) the larva of which is in general form aculeate Hymenoptera belonging to the families of bees and wasps. The changes in colour and structure required to complete the resemblance to particular species are comparatively slight and much less complicated than those needed to produce a likeness to other protected insects. Hence we find that the majority of flies that mimic insects of other orders have bees or wasps for their models. Many of the Syrphidae are banded black and yellow and present a general resemblance to wasps, especially when they alight, the resemblance being enhanced by a twitching action of the abdomen imitating the similar action so familiar in the species of the Hymenoptera. Wasps and flies are usually imitated by peculiar method of flight. They commonly hang poised in the air, then dart with lightning swiftness to another spot and poise themselves again. This habit, the origin of the name "hover-fly" (Eristalis tenax) has been already referred to. But the likeness probably goes deeper than superficial resemblance that appeals to the eye, for spiders which distinguish flies from bees by touch and not by sight, treat drone-flies after touching them as if they were fearfully stinging bees (Calliphora), but in the cautious manner they display towards bees and wasps, warily refraining from coming to close quarters until their prey is securely ensnared in silk. This forcibly suggests that the wasp-like habit may have been adopted in mimicry and not also in the feel of its hairs or the nature of its buzz. Other families of the genus Volucella, larger and heavier in build than Eristalis, resemble humble-bees in colour and form, and it was formerly supposed that the purpose of this similarity was to enable the flies to enter with impunity the nests of the humble-bees and to lay their eggs amongst those of the latter insects. But it has been ascertained that the flies of the genus Volucella, which are also visit for a like purpose the nests of wasps, which they do not resemble. Hence it is probable that this case of mimicry is purely of the negative sort, namely an avoidance of notice and a tendency to save the flies from destruction by insectivorous enemies. The explanation no doubt applies to the mimicry, both in Bommeo and South Africa, of hairy bees of the family Xylocopidae by Asilid flies (Planemoides picta, and D. delphinii) of the family Hymenoptera as well as of inedible beetles of the family Lycidae by Diptera. Numerous other cases of mimicry between Diptera and Hymenoptera might be cited. The Lepidoptera furnish more instances of mimicry, both Batesian and Müllerian, than any other order of insects. In the majority of cases both model and mimic belong alike to the Lepidoptera, and it is often uncertain whether both are inedible (Müllerian mimicry) or whether inedibility is the attribute only of the model (Batesian mimicry). A large number of cases were formerly regarded as belonging to the latter category are now supposed to belong rather to the Batesian type. Similis, the Homopteran mimic protected members of other orders of insects—such as Coleoptera, Hymenoptera and Hemiptera; but perhaps the most singular illustrations of the phenomenon known in the order are exemplified by the larvae of the butterflies and moths which imitate the heads of snakes. Professor Poulton long ago suggested, and supported the suggestion by experimental evidence on a lizard, that the resemblance to frogs is probably produced by the contraction of the anterior segments in such a manner as to suggest a triangular, pointed head with two large dorsal eyes. Subsequent observation on Lady Vespers and on Euphilotes has shown an effecting upon birds that this suggestion is correct. G. C. Gay found that baboons which are afraid of snakes are also afraid of the snake-like larva of the South African Chamaepachys orxis. Finally Sheldrick states that the anterior end of a Bornean species (A. amurrii) offers a striking and detailed resemblance to the head of a snake (Dendrophis picta).
MIMICRY

499

mimetic Lepidoptera. The first is the occurrence of mimicry only in the female sex. The reason for this is to be found in the tendency of many spiders to incapacitate the young of other species. This is a not uncommon phenomenon which is to be observed in many species. Batesian mimicry the explanation is probably this. When an edible species gains protection by mimicking a distasteful one, there is a reduction in the number of individuals of the species, the result being a reduction in the number of the species.

Spiders furnish numerous instances of mimicry. Though simple in kind, many of these are as perfect illustrations of the phenomenon as any found in the animal kingdom. Amongst the orb-weavers of the family Argyopidae there are species belonging to the genera Cyclosa and Cyclothorax which closely resemble small snail-like gastropods as they cling to the underside of leaves with their legs drawn up. Other members of the same family—like Araneus coccinellus, and Pardosa thorunni—imitate beetles of the family Coccinellidae which are known to be distasteful; and certain genera of the family Salticidae (Lycosidae, and Theridiidae) are mimetic species of goldfish and large snails.

The most perfect cases, however, are exhibited by those species which imitate ants. The structural modifications required to convert a spider into the image of an ant are of a more complicated character. The female species of many species of spiders that have the appearance of ants have the same regional division of the body into head, thorax, and abdomen, the same number of legs, a pair of antennae and a segmented abdomen. The males on the contrary have no antennae, no separable head, and an unsegmented abdomen. In the majority of ant-imitating spiders the forepart of the cephalothorax is constricted on each side to resemble the neck of the insect, and in many cases the similarity is increased by the presence of a stripe of white hairs which has the optical effect of cutting out an extra piece of integument, exactly as occurs in analogous cases in insects. Narrowing of the posterior portions of the cephalothorax and abdomen adds to the resemblance. In these species the abdomen reproduces the slender waist of the ant, and frequently transverse bands of hairs represent the segmentation of this region in the ant. The legs become slender and thin, and the first or the second pairs are held up and carried in front of the head to simulate the antennae of the ant. Added to this the spiders commonly copy to the life the mode of progression and the restless activities of their models.

The likeness presented varies considerably in degree from a general resemblance to several species, such as is seen in the Salticid spider (Pelecosoma fitzjamesi) of North America, to a close similarity to particular species, as is shown by the Lycosidae and the Salticidae, and Amelesus fortipes, one of the Thomisidae, which in India imitate and live with the very little red ant (Formica rufa); the bedevilled and dangerous M. M. M. (Myrmarachne), in which the red and black Indian ant (Simus rufipilosus); and the South American species of Clubionidae, e.g. Myrmecus nigrum, which is an accurate copy of the large black ant (Pachycondyla villosa).

Several other cases of this kind are known in which the spider imitates ants, as in the case of Idiobatia mulilloides and I. myrmecomorpha, two South American species of the family Argyopidae, in which the females are protected by strong spine-armature. The males are without these protective spines and are exposed to danger as they wander in search of the webs of the females. In South Africa too the males of a species of Eresidae (Scolyra) resemble and are found in company with a large ant (Camponotus fulgens), which is common on the veld. Like the males of Idiobatia, those of Scolyra wander about by day in search of the females which live concealed in burrows. Many other spiders belonging to the Theridiidae are known to imitate ants, and we may attribute them, the most perfect examples of this phenomenon being found in the families Clubionidae and Salticidae.

Ant-mimicking spiders have been seen now and again to devour their mimics. It has therefore been suggested by some that the case is taken for granted by others that the resemblance comes under the category of aggressive mimicry and that the ants are deluded by this resemblance. They make a deduction from the postponible stages of the colony. That the ants do not destroy them is certain; but that they are deceived by the superficial similarity of the spiders to themselves is highly improbable, for these insects are capable of distinguishing a spider from an ant in all the circumstances. The absence of the wings of the males which are found in the species of Ctenopilus, and the postponible stage of the colony. Moreover, the above-suggested explanation does not coincide with the explanation of the likeness to ants shown by certain insects such as Myrmelepta falax, the ant and leaf-like Mimicry of the leaf-cutter or the oyster-mimic Drosophila (Drosophila simamica), which are plant-eaters. It is probable that one explanation—namely, that of protection—covers all cases of ant-mimicry; and this explanation lies in all probability in the immunity from the attacks of most insectivorous enemies that ants enjoy, and especially from predaceous wasps of the family Pompadidae which annually destroy thousands of spiders to feed their larvae; and since more than one observer has adduced to the support of the theory, species of butterflies, belonging to the Ithominae genus Ithoe and the Danaine genus Thyridia, both unpalatable forms, and the family Lycaenidae, which possess a peculiar and distinct coloration of the same type of coloration by two or more protected insects inhabiting the same district. The significance of this phenomenon, as already stated, was first explained by Fritz Müller; but although the examples of ant-mimetic mimicry are many, in many instances, they are not strictly speaking cases of mimicry at all but of warning coloration. Poisonous or noxious animals usually have some special adaptative structure, sometimes the display of conspicuous coloration, as in the skink; sometimes the emission of sound as in the rattlesnake; sometimes a combination of the two, as in the common porcupine and the large black scorpions of Africa and India. Such characters have been termed by Professor Poulton "aposematic." Neither of the above-mentioned animals is mimicked; but where two or more noxious animals, inhabiting the same district, resemble each other, both being aposematically or warningly coloured, the phenomenon is said to be due to the "Synaposeomy" of Müllerian mimicry. Finally, the likeness of an edible species to a warningly coloured inedible one in the same district protects the former species from predaceous attacks of the latter, the "Pseudosemasy" of Müllerian mimicry.

An important phenomenon connected with insect mimicry is the convergence of several species in the same area towards a common type of coloration and shape, exhibited by one or more than one protected form. The resemblance shows various grades of completeness; and the convergence mimetic models have been discovered by Guy Marsh in Mashonaland. He found on the same day on a bud of vetch, specimens of black ants (Canponotus sericeus and C. cosinicus), black ant-like Hemipterous insects (Megaspis atratus) and the ant-like Orthopteron (Myrmecophana falax) (cf. supra). In this little coterie the ants are beyond question the models towards which the bug and the grasshopper have converged in appearance. Since a species of ant is not protected by the same kind of defence as the bug and the grasshopper, this phenomenon of convergence of several species towards a common type of coloration and shape, exhibited by two or more than one protected form, cannot by any means be regarded as a case of Müllerian mimicry. Very commonly different species of aculeate Hymenoptera, Diptera, and even spiders, produce a mimicry which serves as a defence against the attacks of insects of various orders, so that a considerable percentage of the insect-fauna can be arranged in groups according to the mimicry of the particular model the species have copied. Good illustration of this law have been discovered by Guy Marsh in Mashonaland. He found on the same day on a bud of vetch, specimens of black ants (Canponotus sericeus and C. cosinicus), black ant-like Hemipterous insects (Megaspis atratus) and the ant-like Orthopteron (Myrmecophana falax) (cf. supra).
cited above, with the exception of the first, the synapomorphies mimics are vastly in excess of the pseudosymplesiomorphy; this appears to be the general rule elsewhere. Frequently the groups are composed solely of protected species, so far as is at present known; and some indication of the probability of protected species with exception of course of the model. An example of the latter occurs in Singapore where the vicious red spinning ant (Oxyphyla smaragdina) is mimicked by the larva of a mimicry group of small spiderlings belonging to the family Salticidae and Ameiva fortipes (Thomisidae), there being no reason to suppose that either the moth larva or the spiders are protected forms. Mimetic agreement is analogous to that of the birds described above and have been found in other countries; but the instances cited are sufficient to show how widespread are the influences of mimicry and how profoundly it has modified the insect flora of various parts of the world.

**MIMNERMUS**

Colophon, Greek elegiac poet, flourished about 650-600 B.C. His life fell in the troubled times when the Ionian cities of Asia Minor were struggling to maintain themselves against the rising power of the Lydian kings. One of the extant fragments of his poems refers to this struggle, and contrasts the present effeminacy of his countrymen with the bravery of those who had once defeated the Lydian king Gyges. But his most important poems were a set of elegies addressed to a flute-player and collected in two books called after her name. Mimnermus was the first to make the elegie verse the vehicle for love-poetry. He set his own poems to the music of the flute, and the poet Hipponax says that he used the melancholy μόνος κραθής, "the fig-branch strain," said to be a peculiar melody, to the accompaniment of which two human purificatory victims were led out of Athens to be sacrificed during the festival of Thargelias (Hesychius, s.v.).

Edition of fragments in T. Bergk, Poetae lyrici Graeci; see also G. Vanzolini, Mimnermo (1883), a study of the poet, with notes and ametrical version of the fragments.

**MINOS** (so named from the movements of the leaves in many species which "mimic" animal sensibility), a genus of the natural order Leguminosae, which gives its name to the large subgenus *M. fistulosa* (haricot). It is characterized by small flowers, flowers with valvate corolla, to which belongs also the nearly allied genus *Acacia*. They are distributed throughout almost all tropical and sub-tropical regions, the acacias preponderating in Australia and the true mimoses in America. The former are of considerable importance as sources of timber, gum and tannin, but the latter are of much economic value, though a few, like the *tahiti* plant (*M. lugens*) of Arabia and Central Africa, are important trees. Most are herbs or shrubs, but some South American species are tall woody climbers. They are often prickly.

The roots of some Brazilian species are poisonous, and that of *M. pudica*, having irritating properties. The mimoses, however, owe their interest and their extensive cultivation, partly to the beauty of their usually bipinnate foliage, but still more to the remarkable development in some species of the sleep movements manifested to some extent by most of the pinnate Leguminosae, as well as many other leguminous plants. In the so-called "sensitive plants" these movements not only take place under the influence of light and darkness, but can be easily excited by mechanical and other stimuli. When stimulated—say, at the axis of one of the secondary petioles—the leaflets move upwards on each side towards the movement being propagated centripetally. It may then be communicated to the leaflets of the other secondary petioles, which close (the petioles, too, converging), and thence to the main petiole, which sinks rapidly downwards towards the stem, the bending taking place at the petiole (p in figure) or swollen base of the leafstalk. When shaken in any way, the leaves close and droop simultaneously, but if the agitation be continued, they reopen as if they had become accustomed to the shock. The common sensitive plant of tropical America, but now naturalized in corresponding latitudes of Asia and Africa, is known as sensitive-brier, or natural-brier in the United States. *MIMULUS*, in botany, a genus (nat. order Scrophulariaceae), of showy, hard or half-hardy, herbaceous, rarely shrubby plants, natives of the extra-tropical or mountainous parts of both old and new worlds excepting Europe, but chiefly American. The plants have opposite, undivided leaves, and axillary, generally solitary flowers, whose houses are *M. pudica*, a native of tropical America, but now naturalized in corresponding latitudes of Asia and Africa, and the hardly distinguishable *M. sensitive* and others are also cultivated. Species of the closely allied genus *Schrinkia* are known as sensitive-brier in the southern United States."
MINARET—MINAS GERAES

surprised by the French. Though some maintain that he was not at his best as a leader in battle, as a strategist he was very successful, and he displayed great organizing capacity. The French authorities were compelled to allow him to levy customs duties on all goods imported into Spain, except contraband of war, which peculiarly suited Mohamed to pass without fighting. The money thus obtained was used to build by his orders minarets, that were able to avoid levying excessive contributions on the country and to maintain discipline among his men, whom he had brought to a respectable state of efficiency in 1812. Mina claimed that he immobilized 26,000 French troops which would but for him have served with Murmfort in the Salamanca campaign. In the campaign of 1813 and 1814 he served with distinction under the duke of Wellington. After the restoration of Ferdinand he fell into disfavour. On the 25th and 26th of September he attempted to bribe about rising at Pamplona in favour of the Liberal party, but failed, and went into exile. His political opinions were democratic and radical, and as a yeoman he disliked the hidalgos (nobles). The revolution of 1820 brought him back, and he served the Liberal party in Galicia, Leon and Catalonia. In the last district he made the only vigorous resistance to the French intervention in favour of Ferdinand VII. On the 1st of November 1825 he was compelled to capitulate, and the French allowed him to escape to England by sea. In 1830 he took part in an unsuccessful rising against Ferdinand. On the death of the king he was recalled to Spain, and a portion of the Cortes of Castile gave him the command against the Carlists in 1835, though they feared his Radicalism. By this time, years, exposure and wounds had undermined his health. He was also opposed to Thomas Zumalacarregui (q.v.), an old officer of his in the War of Independence, and an even greater master of irregular mountain warfare. His health compelled him to resign in April 1835, and his later command in Catalonia was only memorable for the part he took in forcing the regent to grant a constitution in August 1836. He died at Barcelona on the 24th of December 1836. Mina was a brave man, and his most striking marks of service have conducted the way against the French in 1810–12 with humanity if they had allowed him, but as they made a practice of shooting those of his men whom they took, he was compelled to retaliate. He finally forced the French to agree to an exchange of prisoners.

By the British by the French

AUTHORITIES.—In 1825 Mina published A Short Extract from the Life of General Mina, in Spanish and English, in London. Mention is made of him in all histories of the affairs of Spain during the first third of the 19th century. His full Memoirs were published by his widow at Madrid in 1851–1852. (D. H.)

MINARET (from the Arabic ماءت; manar or minar is Arabic for a lighthouse, a tower on which war, fire, &c., is lit) a lofty tower, sometimes a watch-tower, built near places of great importance to be seen. It is derived from that of the Pharos, the great lighthouse of Alexandria, in the top storey of which the Mahomedan conquerors in the 7th century placed a small praying chamber. The lighthouse form is perpetuated in the minarets which are found attached to all Mahomedan mosques, and probably had considerable influence on the evolution of the Christian church tower (see an exhaustive study in Hermann Thiersch, Pharos Antike, Islam and Occident, 1900). The minaret is always square from the base to the height of the wall of the mosque to which it is attached, and very often of great height. The upper portion is divided into three stages, the wall of the upper storey being slightly set back behind the one below, so as to admit of a narrow balcony, from which the azan, or call to prayer, is chanted by the muezzin (muèzein, moèddin). In order to give greater width to the balcony it is corbeled out with stalactite vaulting. The balconies are surrounded with stone balustrades, and the upper storeys are richly decorated; the top storey being surmounted with a small bulbous dome. The earliest minaret known is that which was built by the caliph Walid (A.D. 703) in the mosque of Damascus, the next in date being the minaret of the Yama (Qarya) at Cairo (A.D. 879), with an external spiral flight of steps like the conservatories seen in Assyrian architecture. This minaret as also the example of El Hakim (906), is raised on great square towers. The more remarkable of the other Cairene minarets are those of Imam esh-Shafi (1218), Muristan at Kalaun (1280), Hassan (1354), Barkuk (A.D. 1382) and Kait Bey (A.D. 1468). Of the same type are the two minarets added to the mosque of Damascus in the 15th century. In Persia the minarets are generally circular, with a single balcony at the top, cobbled out and covered over. In India, at Ghazni, there are no balconies, and the upper part of the tower tapers upwards; the same is noticed deeper eroded minarets, where the minaret of Kutub is divided into three storeys with balconies at each level. In the well-known tower of the Taj Mahal the four minarets are all built in white marble, in three storeys with balconies to each storey, and surmounted by open lanterns. The minarets of Constantinople are lofty and wire-drawn, but contrast well with the domes of the mosques, which are of slight elevation as compared with those at Cairo.

MINAS [MINOIDES] (c. 1700–1850), Greek scholar, was a native of Macedonia. During the Greek War of Independence he migrated to Paris, where he tried to enlist the sympathies of Europe on behalf of his countrymen and to promote the study of ancient and modern Greek. But his chief claim to recognition consists in his discovery of two important MSS. (amongst others) in the monastery of Mt Athos during his exploration of the libraries of Turkey and Asia, at the instance of M. Villemain, minister of public instruction in France. One of these contained the last part of a treatise on the Refutation of all Heresies, now generally admitted to be the work of Hippolytus (q.v.), the other the greater portion of the Fables of Babrius.

MINAS GERAES (i.e. "general mines"), popularly Minas, an inland state of Brazil, bounded N. by Goyaz and Bahia, E. by Bahia, Espirito Santo and Rio de Janeiro, S. by Rio de Janeiro and Sao Paulo, and W. by Sao Paulo, Matto Grosso and Goyaz. It is very irregular in outline and covers an area of 221,861 sq. m. upon the great Brazilian plateau. Among the Brazilian states it is fifth in size and first in population—3,184,099 in 1850, and 5,504,471 in 1900.

The surface of Minas Geraes is broken by mountain ranges and other elevated land. The latter forming fertile valleys shut in by barren uplands, or campos. The reckless destruction of forests along the watercourses also adds to the barren aspect of the country. The principal mountain ranges are the Serra da Mantiqueira on its southern frontier and its N. extension, the S. do Espinchar, which runs parallel to the Serra do Mar, or coast-range, and separates the inland or campo region from a lower forested zone between the two ranges. Most of the wooded district south of the Mantiqueira belongs to the states of Sao Paulo and Rio de Janeiro, but east of the Espinchar it belongs to Minas Geraes and extends eastward to the Serra das Aymores, on the frontier of Espirito Santo. This zone has an abundant rainfall, dense forests and a fertile soil. It is drained by the Doce, Mucury, Jequitinhonha and Pardo, which have their sources on the eastern slopes of the Espinchar and cut their way through the Aymores to the sea. The tributaries of the Rio Doce cover the slopes of the Serra do Espinchar for a distance north and south of about 200 m. The southern part of this region is well populated, and is covered with coffee and sugar plantations. On the western frontier a northern extension of the great central chain of Goyaz forms the water-parting between the drainage basins of the Sao Francisco and Tocantins, and is known at different points as the Serra do Paranah, Serra de Sao Domingos and Serra das Divisoes. South-east of this chain, between the headwaters of the Paranah and Sao Francisco, are the Serra da Canastra and Serra da Matta da Corde, an irregular chain of moderate elevation running north and south. The highest elevations in the state, so far as known, are Itatiaia (8898 ft.) in the Serra do Mantiqueira, and Caraça (6414 ft.) near Ouro Preto, in the Serra do Espinchar. The Serra das Aymores is a very mountainous region, and Minas Geraes is extremely complicated. The Mantiqueira-Espinchar chain shuts out the streams flowing directly east to the Atlantic, and the boundary ranges on the west shut out the streams that flow into the Tocantins, though their sources are on the actual threshold of the state. Between these two mountain chains the head streams of the Paranah and Sao Francisco are intermingled—the one flowing inland and
MINAS GERAES

southward to the great La Plata estuary, the other northward and eastward across the arid highlands of Brazil to the Atlantic coast in 10° 30' S. lat. Less than 100 m. from the city of Rio de Janeiro and about 60 m. from the coast is the source of the Rio Grande, the larger of the two rivers that form the Paraná. It rises near the peak of Itaiai, on the northern slopes of the Mantiqueira, and flows north-west and west across the Minas plateau, receiving several large tributaries from the south. North and parallel with its course is a low watershed, which separates its drainage basin both from that of the São Francisco and from that of the Paranháyba, the northern confluence of the Paraná. The latter rises on the western slopes of the Serra da Xilutorá and forms one of its numerous tributaries. Its source is in a "knot" of the Serra dos Pyreneos, from which streams flow eastward to the São Francisco and northward to the Tocantins. The central and greater part of the state, however, is included in the drainage basin of the upper São Francisco. Its source is in the Serra da Canastra, and its general course across the state is north by east, during which it receives the Paracatu, Urcuia, Pardo and Carinhana from the west and the Verde Grande and das Velhas from the east. Part of these rivers are navigable for small steamers, and the São Francisco from June to October may be crossed by a small steamer. Important mining is developed in Brazil. All these rivers of the Brazilian plateau are interrupted by falls and rapids. The climate of Minas Gerais is characterized by high sun temperatures and cool nights, the latter often dropping below the freezing point on the higher campos. The mean annual temperature is about 85° in the São Francisco valley, 77° on the campos of the S.E., and 70° on the campos of the W. The year is divided into two seasons—dry and wet—the former lasting from November to May. This division is not so clearly marked in the south, especially in the "matta" (forest) region, where the rainfall ranges from 50 to 65 in. There is much malaria in the wooded districts of the east and on the higher campos, where the daily extremes of temperature are great, lung and bronchial diseases are common. Some of the high plains, however, as at Barbacena, serve as health resorts for the coast districts. Minas Gerais is a mining state, though the mining industry has lost much of its importance through the decline in the output of gold and diamonds. Gold is widely diffused, and abandoned "washings" all over the state show how general the industry was at one time. There were in 1895 five deep mines worked by English companies and one by a French company. One of these, the Morro Velho mine, belonging to an English company, is not only the deepest gold mine in existence (over 2000 ft.), but it has been worked since 1725, and since 1835 by its present owners. Silver is not mined by itself, but is found in combination with gold. In 1908 a rich goldfeld was discovered in the northern part of the state, 5 m. from Montes Claros, in the valley of the Verde Grande River, and attracted large numbers of miners. There are many rich deposits of iron ores in the state, but they only produce a small quantity of charcoal iron for local consumption. Manganese ore is mined for export, and bismuth is reported to have been discovered. Minas Gerais is most widely known for its diamonds, which are found in widely separated parts of the state. The largest and most productive field is that of Diamantina (q.v.) on the head-waters of the Jiquinhonha River, where diamonds were discovered about 1725, and where the celebrated "diamond reservation"—an oval-shaped territory 8 leagues wide by 16 leagues long (Mawe), with Tejucó, now Diamantina, very nearly in the centre—was established in 1730. The mines became crown property, gold-mining was forbidden, and no one was permitted to enter the reservation without a licence. The state monopoly was abolished in 1832, and mining has since been carried on by private enterprise. John Mawe estimates that the annual product was 1000 oz. during the first twenty years, and Castelnau estimates the value of the total output down to 1394 at 300,000,000 fl. No estimate can be made of the contraband, which must have been large. A great decline in the output occurred during the last half of the 19th century; but a new field was discovered in 1908 at Abbadás dos Dourados, in the western part of the state. Other valuable stones, the topaz, chrysolite, aquamarine, amethyst and tourmaline are found.

Agriculture and grazing have become the main dependence of the population—the former in the lower, forested region of the south-east, where coffee and sugar-cane are the principal products, and the latter on the higher campos and river valleys, and on the mountain slopes, where large herds of cattle are to be found, and milk, butter and cheese are produced. The shipping of fresh milk to Rio de Janeiro and butter-making are comparatively new industries. The river valleys of the campo region are also cultivated to some extent. Among the general products are the chestnut, cucumber, tobacco, mandiocá, beans, pork and cotton. Wheat has been produced in some localities, but not on a paying basis, and experiments have also been made with tea. There is a large variety of fruits, and the cultivation of grapes for wine-making is developing into a profitable industry. Railway communication with Minas Gerais includes the following lines: the Central do Brazil (formerly known as the Dom Pedro II.), which starts from Rio de Janeiro and penetrates nearly to Pirapora (its objective point), at the head of navigation of the São Francisco River, with branches into neighbouring districts; the Leopoldina, which runs from Congonhas on the Minas, and the Minas and the Minas and Rio, from Cruzeiro, on the São Paulo branch of the Central do Brazil, into southern Minas; the Mogiana, from Campinas, São Paulo, and runs to Uberaba in western Minas, and is intended to cross into Goyas; and the Bahia & Minas, from the port of Caravelas, in southern Bahia, which runs a short distance into Minas Gerais, and is planned to extend to Philadelphia and beyond. Another line from the port of Victoria, Espírito Santo, northward to Diamantina, Minas Gerais, was under construction in 1908. River transport has some local value on the upper São Francisco and its larger tributaries, and this will be greatly increased when the Central do Brazil railway reaches the head of navigation on that river.

The population of Minas Gerais is chiefly of Portuguese origin, which has been constantly strengthened by immigrants from the mother country. A considerable admixture from other nationalities has resulted from the influx of mining adventurers, and some German colonies have been established in the state. The negro population is large, and there is a still larger contingent of mixed races. The capital is Belo Horizonte (q.v.), or Ciência de Minas; other important cities and towns are: the former capital, Ouro Preto, Barbacena, Diamantina, Baependy (pop. 22,817 in 1890), on the head-waters of the Rio Verde, the centre of a rich tobacco-producing district; Curvelo (8071), north of Sabará in the Rio das Velhas Valley, the centre of a cotton-growing district and cotton manufactures; Entre Rios (7681), the capital of the district of south-east Minas; Januária (8888), a river port of the São Francisco in northern Minas; Juiz de Fora; Marianna (4751), an episcopal town east of Ouro Preto, Mar de Hespanha (1872), the centre of a productive and populous agricultural municipality of south-east Minas; Paraúcatu (21,418), an important commercial centre of western Minas near the Goyaz frontier; Queluz (12,900), on the Central do Brazil railway; Congonhas do Campo (10,921), in the municipality of Queuzel, celebrated for its miracle-working image, its great church and chapels, and the pilgrimages to its shrine; Sabará (4090), a railway junction on the Central do Brazil, and port on the Rio das Velhas; Congonhas de Sabará (14,060), in the municipality of Sabará, where the celebrated Morro Velho gold-mine is situated; São João de El-Rei (5,826) an important commercial mining and pastoral centre, near the Rio das Mortes, connected with the Central do Brazil railway by a branch called the Oeste de Minas; and Uberaba (23,231), a commercial town of the western campos of Minas, connected with São Paulo by the Mogiana and São Paulo railways.

Minas Gerais was first explored by Fernando Dias Paes Leme between 1664 and 1677, though he was not the first European to penetrate it. The discovery of gold in 1662-1665 by bands of adventurers from the São Paulo settlements, led to every occupation and profession being abandoned in the mad rush for the new mines. Minas Gerais at first formed part of the
capitania of São Paulo, but in 1720 it became a separate government and was brought more directly under the Portuguese crown. The arbitrary restrictions imposed upon the colonists aroused disgust and discontent, and in 1729, inspired by a fear that the Portuguese government was about to enforce the collection of its "fifths" of the mining output, which had largely fallen into arrears. Among the conspirators was one José Alves Maciel, who had just returned from France where he had met Thomas Jefferson and had come infected with French revolutionary ideas. A number of residents became involved, among them the poet Thomaz Antonio Gonzaga. Reckless talk in public places led to the arrest of the conspirators. Only one was executed, a poor, untrained and unskilled miner in the old mine at Jaguari. José da Silva Xavier, nicknamed O Tiradentes (the Tooth-puller), the others being imprisoned or hanged. Tiradentes has since been glorified as the pro-martyr of Brazilian independence. In 1812 Minas became a province of the empire created by Dom Pedro I., though a revolutionary outburst had occurred in Ouro Preto the year before. In 1842 a long series of quarrels in Rio de Janeiro culminated in a revolution in Minas Geraes and São Paulo, which was suppressed at Santa Luzia, Minas Geraes, on the 20th of August of that year. The abolition of slavery in 1888 caused much discontent among the planters and in the following year they firmly adhered to the declaration of the republic in Rio de Janeiro.

MINBAR, or Minebar, a term in Mahomedan architecture for the pulpit in a mosque from which the Friday or Mahomedan Sabbath sermon is given (see Pulpit).

MINBU, a district and division of Upper Burma. The district has an area of 3,299 sq. m., and a population (1901) of 233,377, showing an increase of 8% in the decade and a density of 71 inhabitants to the sq. m. The district may be said to consist of low plain-land towards the Irrawaddy, and of undulating country inland. The range of hills is marked and is a continuation of the Arakan hills. Between the plain and the Arakan Yoma range is a distinct line of hills running north and south, and usually called the Nwa-Madaung hills. The submontane valleys are largely cultivated, but are deadly except to those born in them. The chief streams besides the Irrawaddy are the Môn, the Maw, and the Salin, which are largely used for irrigation. At Minbu the town the Irrawaddy is 3 miles wide, with many islands and sand-banks. There are considerable fisheries along the Irrawaddy and on the Paunglin lake, which is a lagoon fed from the Irrawaddy. The Irrawaddy is open to navigation, and realizes an average of £1,000. Oil has been discovered near the mud volcanoes of Minbu, but it seems to lie at too great a depth to be profitably worked.

There is a large area of reserved forest in the district. The chief crops raised are rice, gram, millet, beans, peas, sesamum and tobacco. The betel-vine is largely cultivated along the Môn River. The district, which was in a chronically disturbed state before the annexation, was not reduced till two years afterwards, many officers losing their lives, among them Phayre, the first deputy-commissioner. The annual rainfall varies greatly over the district. It is very considerable on the Arakan and under the Arakan Yomas, and very slight towards the Irrawaddy. The thermometer rises to over 109° in the hot months, and the mean of minimum in December is about 49°. Minbu, the district headquarters, stands on the Irrawaddy. It had a population of 5780 in 1901. The river steamers in the dry season can come no nearer than two miles to the south of the town.

The division includes the districts of Thayetmyo, Pakkókku, Minbu and Magwe. It has a total area of 17,172 sq. m. and a population (1901) of 1,476,080, showing an increase of 8% in the decade and giving a density of 65 inhabitants to the square mile. It is crossed by the Irrawaddy.

MINCHINHAMPTON, a town in the Stroud parliamentary division of Gloucestershire, England, 4 m. S.E. of Stroud. Pop. (1901), 3727. It lies high on a slope of the Cotswold Hills; Minchinhampton Common being a fine open upland. The church of Holy Trinity, largely reconstructed, contains many brasses and memorials. The manufacture of woollen cloth is the long-established staple of Minchinhampton. Prehistoric remains have been discovered on the common, and earthworks are also seen; while the name of Woeful Dome Bottom, a neighbouring valley, perhaps indicates the scene of a defeat of the Danes (c. 918).

MINDEN, a town of Germany, in the Prussian province of Westphalia, 44 m. by rail to the W.S.W. of Hanover, on the left bank of the Weser, which is spanned by two bridges. Pop. (1905), 25,428. The older parts of the town retain their narrow and crooked streets. The cathedral tower dating from the 11th century, illustrates the first step in the growth of the Gothic spire in Germany. The nave was erected at the end of the 13th century, and the choir in 1377-1379. Among the chief edifices are the old church of St Martin; the town hall, with a Gothic façade; the law courts and the government offices, constructed, like many of the other buildings, of a peculiar veined brown sandstone found in the district. The town has a statue of Frederick William I., the great elector of Brandenburg. Minden contains a gymnasium and several hospitals, besides other charitable institutions. Its industries include linen and cotton weaving, dyeing, calico printing, brewing, ship-building and the manufacture of tobacco, glass, soap, chocolate, leather, lamps, chicory and chemicals. There is also some activity in the building of small craft.

MINEDO, Minud, Minu, Minas, a city of Minas Geraes, near the coast of the west. The birth of Minden was fought on the 1st of August 1579 between the Anglo-Allied army commanded by duke Ferdinand of Brunswick and the French under Marshal Coutades, the latter being defeated. The most brilliant episode of the battle was the entire defeat of the French cavalry by the British infantry (with whom there were some Hanoverian troops); but Minden, though it is one of the brightest days in the history of the British army, has its dark side also, for the British cavalry commander Lord George Sackville (see SACKVILLE, VISCOUNT) refused to obey the order to advance, several times sent by Duke Ferdinand, and thereby robbed the victory of the decisive results which were to be expected from the success of the infantry. For an account of the battle and of the campaign of which it is the centre, see SEVEN YEARS' WAR.

See STOTY, Kurzer Abriss der Geschichte Mindens (Minden, 1879); Bölsche, Skizzen aus Mindens Vergangenheit (Minden, 1897); Holseher, Beschreibung des vormaligen Bistumes Minden (Münster, 1877).

MINEHEAD, a market town and seaside resort in the Wellington parliamentary division of Somersetshire, England, 188 m. W. by S. of London by the Great Western railway. Pop. of urban district (1901), 2511. The town has three parts: the Upper, built on the sides of a lofty foreland known as North Hill; the Lower; and the Quay Town, with many ancient houses, stretching for about a mile beside the harbour. It is much visited for the sake of its mild climate, the grand cliffs, moors and hills of the neighbourhood, and the beach, admirably suited for bathing. St Michael's, the parish church, has a striking Perpendicular tower, an arch of carved oak dividing its nave and
chancel, a magnificent rood-loft, and a 13th-century monument, doubtfully described as the tomb of Bracton, the famous lawyer, whose birthplace, according to local tradition, was Bratton Court in the vicinity. 'Coaches for Porlock and Lynton start from the town.

There is no evidence of the existence of Minehead (Mannheire, Mancheald, Mynheved) in Roman or Saxon times. The town owed its origin and growth to its position on the shores of the Bristol Channel, and its good harbour developed an overseas trade with Bristol, South Wales and the Irish ports. The De Mohun family were overlords of the town from 1086 to the 14th century, when they were followed by the Luttrells, who are the present owners. It is possible that Minehead had a corporate existence during the 15th century, as certain documents executed by the portreeve and burgesses at that date are preserved, but no record of the grant of a charter has been found. A charter of incorporation given by Elizabeth in 1556 vested the government in a portreeve, a steward and twelve burgesses, the continuance of the corporation being subject to the port and harbour being kept in repair. This condition being unfulfilled, the charter lapsed in the reign of James I., and an attempt to obtain its renewal in the 18th century failed. The corporation was replaced by two constables chosen annually in the court leet of the manor until 1804, when an urban district council was appointed. The borough returned two members to parliament from 1558 until disfranchised by the Reform Act of 1832. A weekly market on Tuesdays and a fair (Sept. 29 to Oct. 2) were held by the lord of the manor from the 13th century, but the date of the grant has not been found. In 1465 a second annual fair on the 1st of May was granted by Edward IV., which is still held on the Wednesday in Whitsun week. The other fair has been discontinued, and the market day has been changed to Wednesday. During the 16th, 17th and 18th centuries Minehead had a considerable coastwise trade in wool, grain and wine, but began to decline owing to the migration of the woollen industry to the north of England, and to the decay of the herring fishery. A renewal of prosperity began when it acquired a reputation as a watering-place.

See Victoria County History: Somerset; F. Handcock, Parish and Borough of Minehead (1903).

MINEO, a town of the province of Catania, Sicily, 24 m. S.W. of Catania by rail. Pop. (1911), 9288. It occupies the site of the ancient Menaenum, founded by Ducetius in 459 B.C. There is some doubt as to whether this town was also the birthplace of Ducetius, owing to confusions in nomenclature (see E. A. Freeman, History of Sicily, ii. 361). Remains of ancient fortifications still exist, though it seems uncertain whether they are of Greek or of Byzantine origin (Notizie degli Scavi, 1899, p. 70). Four miles to the north is the Lake Pallirrion, an alkaline crater, which still sends up carbonic acid gas. By it was the temple of the Palici, twin Sical gods, the most holy place in Sicily, where an oath taken was especially binding, and an inviolable asylum for fugitive slaves. There is now nothing to suggest twin deities; in ancient times there were probably two craters, whereas now there is only one. It was here that Ducetius, a few years later, founded a new seat for his power, the city of Palica.

MINERAL DEPOSITS. The subject of mining (q.v.) can only be understood after the general features of mineral deposits have been elucidated. In this article deposits of all kinds of useful minerals are included, whether they are metalliferous or earthy. In general practice it is customary to treat the former under the name "ore-deposits" and the latter as the "non-metalliferous". This is warranted because in a large degree different geological problems are presented and different methods of mining are pursued. Nevertheless there are other important similar or common features and they may be classed together with great advantage.

The word "ore" is used in several meanings, each of which depends for its special significance upon the connexion. In ore, a metalliferous mineral, and in this sense it appears in works on mineralogy and petrology. In former years and in connexion with practical mining an ore was defined as a compound of metal or of metals with one or more non-metallic elements, called mineralizers, of which oxygen and sulphur were the chief. The ore must, in addition, be sufficiently rich to be mined at a profit. Native metals not being compounds were not considered ores. The product of the copper mines on Keweenaw Point, Lake Superior, was, and to a great extent is, a rock rather than copper ore, and the native gold in quartz is often described as gold quartz rather than gold ore, but these restrictions are gradually disappearing. An ore may therefore be defined as a metalliferous mineral or aggregate of metalliferous minerals mingled with a greater or less amount of barren materials called the "gangue," and yet rich enough to be mined at a profit. When not proved to be sufficiently rich to be remunerative, the aggregate is called "mineral." The "metal" of to-day may be changed by the advent of a railway or the rise in the price of metal into the "ore" of to-morrow. The question has repeatedly appeared in litigation involving contracts or property rights.

Since the greater number of the ores are believed to have been precipitated from aqueous solutions, or to have been otherwise formed through the agency of water, the term "ore-deposit" has resulted; and inasmuch as nearly all the other useful minerals owe their origin to the same agent, the term "mineral deposit" is equally well justified. A few, however, have been produced in a different way, such as certain iron ores of igneous origin; and coal, the accumulations of vegetable material in coal beds. These latter, the igneous masses and the vegetable accumulations, being placed in two divisions by themselves, we may group the larger number into two main classes, depending on their precipitation from solution or from suspension. In the case of solution we will further subdivide on the place, and therefore in large part on the cause, of precipitation, since these are the questions chiefly involved in actual development.

Especially in connexion with ore-deposits widening experience has modified the older conceptions of relative values in the several types. In the early days of geology, Cornwall and Saxon were the two regions where the most active and influential students of ore-deposits were trained and where the principal books relating to mining originated. The pronounced and characteristic fissure veins of England and Germany became the standards to which the phenomena met elsewhere were referred, and by means of which they were described. This particular form, the fissure vein along a fault, assumed a predominating importance, both in the thought and in the literature of the day. Widening experience, however, especially in the Cordilleran region of North America, and in the provinces of South America, in the case of copper, and in South Africa, has brought other types into equally great and deserved prominence. Comprehensive treatment to-day therefore departs somewhat from earlier standards.

As far as analyses and estimates permit, the common useful metals occur in the earth's crust in approximately the following percentages:

<table>
<thead>
<tr>
<th>Metal</th>
<th>Percentage</th>
</tr>
</thead>
<tbody>
<tr>
<td>Aluminum</td>
<td>4.1%</td>
</tr>
<tr>
<td>Copper</td>
<td>1.7%</td>
</tr>
<tr>
<td>Iron</td>
<td>5.6%</td>
</tr>
<tr>
<td>Manganese</td>
<td>0.07%</td>
</tr>
<tr>
<td>Nickel</td>
<td>0.01%</td>

<tr>
<td>Cobalt</td>
<td>0.0005%</td>
</tr>
<tr>
<td>Tin</td>
<td>0.00%</td>
</tr>
</tbody>
</table>

By the letter x is meant some undetermined digit in the corresponding place of decimals. Apart from aluminium, iron, manganese and nickel, the figures show how small is the contribution made by even the commoner metals to that portion of the mass of the globe which is open to observation and investigation.

As compared with the earth's crust at large certain of the metals are known to be locally present in favourable, usually igneous rocks in associa- tion with gold and silver, and in the following determinations which have been made upon large samples of carefully selected materials. Copper, 0.000%; lead,
MINERAL DEPOSITS

0-001-0-008; zinc, 0-0048-0-0009; silver, 0-00007-0-00006; gold, 0-00002-0-00004. Iron and aluminium seldom fail, and vary from 1 to 2% as a minimum, up to 25% as a maximum.

In order that the several metals may constitute ores, their percentages must be the following—the percentages of each vary with favourable or unfavourable conditions at the mine, and can therefore be expressed only in a general way; ores favourable to milling and concentration may go below these limits, and the mingling of two metals of which one facilitates the extraction of the other may also reduce the percentages:

Cobalt is a by-product in the metallurgy of nickel and is usually in much inferior amount to the latter.

When we compare the first and second tabulations with the third it is at once apparent that with the possible although only occasional exception of iron the production of an ore-body from the normal rocks which constitute the outer mass of the earth requires the local concentration of each of the metals by one or several geological processes, and to a degree that is only occasionally sufficiently expressed by the words "ore-body" and "nose," and for the most part can therefore only be recognized by the observer as a "deposits" rather than as a mineral deposit. It is therefore, of course, an instance of the exceptional good fortune when one is discovered, and it is only the part of ordinary prudence to develop and utilize it as one would treat a resource which is limited and subject to exhaustion.

The great classes: the ores proper, which contain the metals; and the barren minerals or gangue, which reduce the yield.

The ores are generally subdivided into two subgroups, the sulphides and related compounds containing arsenic, antimony, tellurium and selenium; and, second, the oxidized compounds embracing oxides, carbonates, sulphates, silicates, phosphates, arsenates, chromates, &c. With the oxides are placed, because of related geological occurrence, a few rare compounds with chlorine, bromine and iodine into which silver more than any other metal enters, and to the same group we may add a few metals which occur in the native state. Iron, manganese, aluminium and tin differ from the rest of the metals in their original occurrence. With the oxidized form, whereas the others with the exception of gold, platinum, and possibly copper, in their first prehistoric state are in the form of sulphides or related compounds. Only by subsequent changes, characteristic of the upper parts of the deposits, do they pass by oxidation into the minerals of the second group.

With regard to the nature and source of the water which serves to gather up the widely disseminated metals and concentrate them in ore-bodies two contrasted views are now current, not necessarily antagonistic but applied in different degrees by different observers. The older view attributes the water primarily to the rainfall, and therefore it is called meteoric water. After falling upon the surface the meteoric water divides into three parts. The first, and smallest, evaporates; the second, the largest portion, joins the surface drainage and is called the run-off; while the third, intermediate in amount, sinks into the ground and mingles with the ground-waters. The ground-waters rise in springs, usually fed from no great depth, and themselves pass into the surface drainage after a small subterranean journey. While as a rule the ground-water level is fairly definite, yet it sometimes displays even in the same mining district great irregularity.

The elevation of active circulation and work of the descending meteoric waters between the surface and the ground-water level was called by Franz Porsepy (1836-1895) the vadose or shallow region ("Genesis of Ore-deposits," Trans. Amer. Inst. Min. Eng., xxiii., xxiv., 1893; reprinted as a book, 2nd ed., 1902). It has long been recognized by miners as the home of the oxidized ores, and the place of the work of the descending waters. The deep-waters are relatively motionless and their movements as far as visible are comparatively slow. But the really important feature of the ground-water as regards the filling of veins is the depth to which it extends. This remained a somewhat indefinite matter until L. M. Hoskins showed mathematically that cavities in the basement rocks begin impossibilities at about 1,000 metres. Down to some such portion of depth as that the ground-water was believed by many to descend; to migrate laterally; to experience the normal increase of temperature with depth; the effect of pressure; the increased efficiency as a solvent peculiar to the conditions; and finally with a burden of dissolved gangue and ore to rise again, urged on by the "head" of the descending column. In its ascent it was supposed to fill the veins. Mining experience has, however, indicated that the known ground-waters are comparatively shallow and seldom extend lower than 50-000 metres. It is conceivable that during faulting and the formation of great dislocations this upper reservoir might be tapped into greater depths and set in limited circulations through deeper-seated rocks. But so far as these objections have weight they have greatly restricted the vertical range of the meteoric ground-waters as they were formerly believed to exist.

In contrast with the meteoric waters outlined above, other waters are believed by many geologists to be given off by the deep-seated intrusive rocks, and are generally called magmatic.

We are led to this conclusion by observing the vast quantities of steam and minor associated vapours which are emitted by volcanoes; by the difficulty of accounting in any other way for the amount and composition of certain hot springs; and by the marked and characteristic association of almost all ore-deposits in the form of veins with eruptive rocks. That igneous masses have been connected with the formation of veins is further brought out by the following general consideration, which has hitherto received too little attention. Aside from pegmatites, veins rich enough to be mined and even large veins of such barren gangue-minerals are exceptional phenomena when we compare the regions containing them with the vast areas of the earth which have been carefully searched for them and which have failed to reveal them. As components of the earth's crust the useful metals except iron and aluminium are extremely rare. Some sharply localized, exceptional, and briefly operative cause must have brought the veins into being. The universal circulation of the ground-water of meteoric origin fails to meet this test, since if it is effective we ought at least to find veins of quartz and calcite fairly universal in older rocks. In North America, moreover, instances of homogeneous veins, which have been studied date from the Mesozoic and Tertiary periods. The ore deposits of older date are chiefly of iron and manganese and can be satisfactorily explained in many cases by the reactions of the vadose region, or by crystallization from molten masses.

In summary it may be stated that the meteoric waters are of great importance and of unquestioned efficiency in the shallow vadose region, or, as named by C. R. van Hise, "the zone of weathering." In it the disintegration of rocks exposes them to the searching action of solutions, and the portions of ore-bodies already deposited undergo great modifications. The deeper and far more immovable ground-water probably extends to but moderate depth and is chiefly affected as regards movement by the head of waters entering heights of land and by local intrusions of igneous rocks. It is very doubtful if the normal increase of temperature with depth produces much effect. The meteoric waters are of altogether predominant importance in all surface concentrations of a mechanical character. The magmatic waters, on the other hand, seem to be of paramount importance and of great efficiency in the deposition of ores in the immediate vicinity of the eruptives, and in the formation of veins which are reasonably to be attributed to uprising heated waters in regions of expiring vulcanism. They start with their burden of dissolved metals and minerals under great heat and pressure, amid conditions favourable solution, and migrate to the upper world into cooling and greatly contrasted conditions which favour precipitation. Undoubtedly they are responsible for many low-grade deposits
which have later been enriched by the action of descending meteoric waters. They are more copiously yielded, so far as we may judge, by acidic magnas than by basic ones.

The natural waterways are furnished by the cavities in rocks. They vary in size from very minute pores, where movement is slow because of friction, but where solution takes place, through others of all dimensions up to great fault-zones. The smallest cavities are the natural pores of minerals; cleavage cracks; the voids along the contacts of different minerals; cracks from crushing during dislocation; cellular lavas; and cavities in necks among the grain of the jebbles, or boulders of fragmental rocks; joints, fissures, and faults. So far as waters have deposited ores and yielded ore-bodies by subterranean circulations the latter are guided by some such controlling influence as these in all cases, and they will be selected as the governing principle in a large part of the scheme of classification. The types will be reviewed in the following order:

I.—Of Igneous Origin.

A. Eruptive masses of non-metalliferous rock.
B. Basic segregations from fused and cooling magnas.
C. Deposits produced in contact metamorphism, most commonly by the action of intrusive masses on limestones.
D. Pegmatoids.

II.—Precipitated from Solution.

A. Surface deposits.
B. Impregnations in naturally open-textured rocks.
C. Impregnations and replacements of naturally soluble rocks.
D. Deposits along broken antecedent summits and in synclinal troughs.
E. Deposits in shear zones.
F. Deposits in faults.
G. Deposits in volcanic necks.

III.—Deposited from Suspension.

A. Plecos.
B. Residual deposits.

IV.—Carbonaceous Deposits from Vegetation.

I. Of Igneous Origin.—A. Eruptive masses of Non-metalliferous Rock.—Among the non-metallic objects of mining and quarrying which are to be met with in the course of mining, building stone is the chief. Granites, syenites, and other light-colored rocks are the most important. These rocks occur as intrusive masses called bosses when of limited extent and diameter, and batholiths when of vast, irregular area. The main point of importance is the jointing and cleavage, which should in each case yield blocks as nearly rectangular as possible so as to save tool treatment. Dark, basic igneous rocks in dikes, sills, and surface flows are employed for maccadam, and are often of excellent quality for this purpose.

B. Basic Segregations from Fused and Cooling Magnas.—A few ore-bodies, of which the best-known involve iron, are believed to result directly in the formation of which metallic rocks cools and crystallizes. Thus magnetite, one of the common iron ores, is a widely distributed component in the eruptive rocks, rarely if ever failing in any variety. It is one of the first minerals to crystallize, and is often found in a higher specific gravity than the other constituents. There is reason, therefore, to believe that, forming in some molten magnas in relatively large quantity, it sinks to or toward the bottom of the mass until it is at least greatly enriched with it, if not actually changed to iron ore. If the molten rock, after passing through a stage of partial crystallization, moves toward the surface of the earth, the body of ore may occupy almost any position in it other than the bottom. The flowing of the magma in original movements or from pressure sustained in subsequent metamorphic processes, or both, may give the ore the klinitic shape which is characteristic of igneous bodies the world over. Almost all iron ores of recognized eruptive origin contain titanium oxide in amounts from a few units to over 40%. They are most frequently found in dark basic rocks. These ores are not at present of much commercial value because of the difficulties of treating titaniferous varieties in the modern blast furnace practice, but there is little doubt that in the near future they will be extensively exploited.

Non-titaniferous magnetites, which often form lens in gneissoid rocks of more acidic character than those with which the titaniferous are associated, are likewise believed to be of igneous origin. These are equally effective deposits of metallic deposition followed by metamorphism.

Besides magnetite, chromeite is a characteristically igneous mineral and is always found in the richly maganese rocks. Whether the relatively high iron content, which appears to come from the line arrestions from fusion, or whether they have segregated from a finely disseminated condition during the change of the original eruptive to argenteous, is a matter of dispute, but the general trend of later opinion is toward an original igneous origin. Although not strictly an ore, corundum is another mineral which is the direct product of igneous action.

A. Ore-body which marks a connecting and transitional member between those just treated and those of the next group is furnished by the sulphides of iron, nickel and copper which are found in the outer borders of basic igneous intrusions. Observers differ somewhat as to the reasons for their occurrence, but all agree purely of the nature of crystallization from fusion or those brought about by the agency of gases or other highly heated solvents in the cooling stages. These important economic ores are also produced by the mingling of nickel and copper which are developed in the large form in the region of Sudbury, Ontario, Canada, and are now the principal source of nickel for the world.1 The ores are chalcopyrite and bornite, the latter containing generally about its mass at Sudbury, the mineral pentlandite, a nickel-iron sulphide and the real source of the nickel. With the base metal there are also found minute traces of the metals of the platinum group. Wherever these deposits have formed, however, there have been overprinted borders of intrusive masses. The sulphides constitute an integral part of the rocky mass, which shows almost no signs of alteration or vein production in the ordinary sense. Only some slight reamalgamations have subsequently taken place through the agency of water, but all this is a small factor in the total.

C. Ore-Bodies produced by Contact Metamorphism.—Great bodies of nickel have been formed in a molten and highly heated condition through other rocks when at a distance below the surface of the earth. After coming to rest they have remained during the cooling stages for long periods in contact with the surrounding walls. All igneous rocks are more or less richly charged with aqueous vapour, doubtless in a dissociated state; with carbonic acid and probably with other gases, especially those involving sulphuric acid. When the cooling commences, the fusions with them silica, iron, alumina and metallic elements in less amount, of which copper is the commonest, but among which are also numerous lead, zinc, gold and silver. If the rock standing next the intrusive mass is limestone, the silica and iron, and to a less degree the alumina, combine with the lime to the elimination of the carbonic acid and produce extensive zones of lime silicates, of which garnet is the most abundant. Disseminated throughout these gneiss-zones are found small masses of pyrite and chalcopyrite, often in amounts sufficient to yield large ore-bodies. Again in the limestone outside the garnet-zones, but none the less closely associated with the rocks, are bodies of pyritic sphalerite and calcite, the ores of lisbee and Morenci, Maine, or of Aranazu near Concepcion del Oro, Mexico, and of many other parts of the world not yet studied in detail are of this type. The eruptive which most frequently produces contact zones of a metallic character, since among eruptives these are the ones most richly charged with gases. When the copper ores are of low-grade in their original deposition it often happens that processes of secondary enrichment, which are later described, are required to bring them up to a richness which warrants mining. Less often than copper appear lead, zinc or gold ores in the same relations.

2. Deposits from Solution.—Of the objects of eruptive activity reeds also to be briefly mentioned before passing to the discussion of the ore-bodies, which have hitherto chiefly occupied students of the subject. In the regions surrounding intrusive masses of granite we almost always find lilke ores of or which may be called carbonatite, mica radiating outward, it may be, for very long distances. They are believed to be produced by emissions from the eruptive itself such as those described by Garnet-zones, and when the carbonatite is lime, the veins are called pegmatoids. They are characteristic carriers of tin and of minerals containing the rare earths, and common are known to yield gold or copper.

II. Precipitated from Solution.—A. Surface Deposits.—The chief ore-body under this type is furnished by iron. The peculiar chemical property possessed by this metal of having two oxides, a ferric, which is relatively soluble, and a ferric, which is insoluble, leads to its frequent occurrence in waters of a comparatively quiet condition. Ferruginous solutions, which may be composed of solutions, or as salts of organic acids, or ferrous carbonate, the last-named dissolving in an excess of carbonic acid. On being exposed to the atmosphere when the solutions come to rest, or to the breaking up of organic acids, or to alkaline precipitation in the case of some water alage, the hydrated sesquioxide $2Fe_2O_3·H_2O$ is precipitated as the familiar beds of bog ore. The ore usually forms earthy aggregates or crusts and cakes, but may also, as in the interesting case of the iron ore of Charlestown, Colorado, be deposited as a very rich in iron and are apt to have much sand and clay intermingled. If subsequently buried under later sediments they may become fused, and if fused changed through the action of the孙子 of the Clinton iron ores of the eastern United States. These widely extended beds in the lower strata of the Upper Silurian are often oolitic red hematites, consisting of concentric shells of iron oxide and iron...

chaledonic silica, deposited around grains of sand. The most extensive of all ore-beds of this type and the mainstay of the German and Belgian smelting industry, are the Jurassic ores, locally called mints. In the northeastern United States, the principal and several subordinate beds are distinguished, which furnish a product ranging from 30 to 40% of iron and between 1 and 2% of phosphoric oxide (P₂O₅). They are generally believed to have been formed by the replacement of some of the rock by the metal, sulphuric acid, resulting in the precipitation of the metal and the formation of ores. The iron was furnished by the drainage of the land and was precipitated, according to Van Werveke, as silicate, carbonate, sulphide and oxide.

No less than two billion tons of iron is believed to be available. Very similar deposits occur in the Cleveland district, England, in the Middle Lias.

In the presence of much organic matter which creates reducing conditions, pyrite, or iron sulphides, may result and afford the ores of this type extensively utilized in the Scottish iron industry and formerly of some importance in the eastern United States.

True impregnations of ore have been more or less manganese, and manganese ore itself may result by closely related reactions, since manganese is very similar to iron in its chemical properties. Alumina is yielded by deposits of bauxite, the hydrated oxide which in the states of Georgia and Alabama, of the United States, are the result of surface precipitations. In the depths it is believed that pyritic shales exist. The oxidation of the pyrite supplies sulphate, the reaction of solution of the organic matter, rising to the surface along a marked series of faults, the aluminium sulphate meets calcium carbonate in an overlying limestone, and the aluminium hydrate is precipitated as concretions at the vents of the springs.

Of scientific importance but as yet not of commercial value are the siliceous sinter deposits contained in the hot springs which are the vent of efflux of hot water. While precipitations in the eruptions of the lake. Rising to the surface along a marked series of faults, the aluminium sulphate meets calcium carbonate in an overlying limestone, and the aluminium hydrate is precipitated as concretions at the vents of the springs.

A mineral deposit is an accumulation of mineral matter which is formed by the concentration of mineral matter from nature. The term is not limited to mineral matter, but includes organic substances as well. The deposit is formed by the concentration of mineral matter from nature. The term is not limited to mineral matter, but includes organic substances as well.

A mineral deposit is an accumulation of mineral matter which is formed by the concentration of mineral matter from nature. The term is not limited to mineral matter, but includes organic substances as well.

B. Impregnations in Open-Textured Rocks.—In a number of instances in various parts of the world, especially in the island of Trinidad, in the Caribean Sea, that petroleum with an asphalt base has reached the surface, has become impregnated with asphalt, and has been used as a fuel for street-paving or other purposes. The asphaltic pitch-lakes are formed which may be of great commercial value.

Again, if large sheets, crusts, stalactites and stalagmites, deposited from carbonate water by the escape of the solvent, are deposited in the cave, the deposit is an impregnation in an open-textured rock. The deposit is formed by the concentration of mineral matter from nature. The term is not limited to mineral matter, but includes organic substances as well.

C. Impregnations and Replacements of Naturally Soluble Rocks.—Ore-deposits of great importance appear in different regions which can be interpreted as replacements having been formed by the replacement of some or all of a rock with the metal. Solubility of the rock, however, is common to rock to yield, because of its soluble nature, but important cases occur of ores composed of silicates. Replacement implies the complete solution of the original rock and its replacement by another substance, or by a new molecule by a molecule, in the position of the original minerals but without, as in pseudomorphs, the necessary reproduction of crystalline forms. Some water must of course introduce the ore-bearing solutions, but it may be slight compared with the great size of the resulting ore-bodies. Lead and zinc ores, often carrying some silver, are those most widely distributed, as they were also the first recognized as deposits of the character. More than any other metals their association with limestone is pronounced. The replacements may be found near the supply fissure as in the great zinc deposits near Aachen, or the supply fissures may be absent, as at Leadville, Colorado. While they are rare, they are often close along its contact with some relatively impervious stratum, which seems partly to have directed the circular flow of the stratum, while precipitation took place. With the lead and zinc sulphide deposits of the Longhorn, Texas, and chalcopyrite are commonly associated in greater or less degree, the copper, increasing locally. The pyrites are exposed to oxidation above the ground, the waters and mining in the upper parts of the region have been often directed against the carbonate and sulphate of lead, or the munged carbonate and hydrated silicate of zinc.

A non-metallic deposit formed by replacement and of much metallic value is the limestone, which is furnishing sulphur when derived from gypsum, in the Sicilian and other localities of Europe.

D. Deposits along Anticlinal Summits and in Synclinal Troughs.—When they are exposed to the air, these deposit, and, if still or brittle like limestone, often crack in limited fissures, which in anticlines open upward and in synclines downward. They thus yield joints in relatively great numbers. Soft rocks, such as shales, are moulded by the strata without fracturing. Very gentle folds seem to have yielded such abundance of cracks in the lead and zinc district of the Upper Mississippi Valley as to cause the so-called "gash veins" which have been worked for many years. The cracks are not vertical, but often run horizontally and are due to the parting and buckling of individual beds. The resulting ore-bodies are chiefly limited to a single great stratigraphical bed, and have been formed by the great infiltration of galena, blende and pyrite from overlying formations.

When strata are still enough to buckles under violent folding and part so as to produce openings of a crescentic cross-section which afterwards become filled with gelatinous masses, and are marked in the gold veins of Victoria, Australia, and in pitching antilines of a much larger character in Nova Scotia. In many districts of the metallic ore-beds of the Lake Superior region, now the most productive of all the iron-mining districts, in a series of sedimentary formations, generally of Huronian age, and with associated eruptives, there occur strata consisting of a cherty iron carbonate, which were probably originally marine deposits akin to glauconite. They rest upon relatively impervious rocks, and are often penetrated by basaltic dikes. The entire series has been folded, so that the cherty carbonate has been rent into shreds, and the bands, even of relatively tight, impervious rocks. The descending surface waters have next altered them, have taken the iron into solution, and redeposited it in the strata as irregular and massive veins of impervious haematite. The silica has usually been precipitated elsewhere.

The most important of the non-metallics which occur along anticlinal summits are petroleum and natural gas, but it is true only in a very limited sense that they are associated with these regions. The general cause of the accumulation is, however, the same as that of the metallic minerals, i.e. that storage cavities are afforded. In the most productive oil-fields it is the gentle and low告訴 basaltic rocks impervious to any passage of water, either sandstones or limestones, at the crests of anticlines and beneath impervious shales which do not shatter or crack with gentle folding.
The gold-bearing rocks of the Transvaal present a good illustration. Beds of conglomerate containing quartz and feldspar, and pebbles have experienced crushing and shattering, and have had their natural porosity much enhanced by those after-effects. Solutions of gold, coming through, have encountered pyrites and have had their bodies precipitated, a result which is often broken and granulated. In other regions shearing has led to sheeting and opening of the rocks by many parallel cracks but almost always with such marked displacement that the next type may be correctly described as an extension of the first zone. The fault-line is a natural transition to the fault and closely related to it.

F. Deposits in Faults.—This type of ore-body was one of the earliest established, and has always been prominent in the minds of students of the subject since the first systematic formulations of our knowledge. The dislocation of the earth’s crust by faults has furnished either clean-cut fissure or else lines of closely set parallel fractures, whose occurrence in unconsolidated sedimentary rocks is comparatively great. The faults go to relatively profound depths and furnish therefore waterways of extended character, which may reach from regions of heat and pressure in depth to regions of cooler and lighter pressure above. As such a fault is favourable to ore deposition. From all these reasons it is not surprising that the “true fissure vein” based on a profound fault has been the ideal of the prospector’s search in many parts of the world. This ideal of ore deposits has been elaborated and modified by others, and is often referred to as the “Sonora” type of deposit.

Faulting often leads to great shattering of the country rock, and instead of being a clean-cut open cavity, there results a brecciated belt which may then be cemented by infiltrating ore and gangue. In the gold district of the Comstock there is a bonanza deposit which are succeeded by leaner stretches. The movement of the walls produces the polished surfaces specifically called “slickensides,” parallel to which the ore-chutes often run. The change in the character of the entering solutions from time to time gives a banded character to the deposit, so that the ore-bodies may be banded or zoned. As the centre forming solutions have proceeded another and another layer of ore may be added, and the deposit becomes multiple, as observed in the Drukenkolk lode, California, and in the Brooklyn mines in the Adirondacks, New York.

A very peculiar non-metallic deposit found in fault-fissures and imitating the ordinary veins in all essentials is furnished by the asaphallic minerals, and described as being “carbonaceous coal” and often in mineralogy as “gahramite,” “albertite,” “tertoite,” “gilsonite,” &c. Petroleum with asaphallic bases have percolated into fault-fissures and have there deposited upon evaporation and oxidation their dissolved burdens. The black coal mineral presents all the geological relations of a fissure vein and is mined like so much ore.

K. Necke.—A very unusual ore-body is furnished by this type, which is only known in a few instances. In two cases, however, in Colorado, the Bassick and the Bull-Domingo, there occur chinks of elliptical cross-section filled with rounded boulders, and believed with much reason to be the tubes of small explosive volcanoes. After brief periods of activity they became waterways for uprising heated solutions which filled the interstices with the transported materials of their running streams, and settled with them wherever the current stopped. Concentration may thus ensue and beds of black sand result. If again deposits of loose sand containing more or less magnetite are exposed to the surf of the ocean, or even to the bays and inlets of the sea, they may be driven or washed by the waves into the streams, and furnished with the lighter materials. Iron sands of either of these varieties are usually termed “stabilized ilmenite,” and the black sand or beach gravel may be gold or platinum in sufficient amount to be of value.

While magnetite is the commonest of the ores to be found in placer deposits, gold is the metal which usually gives them value. Wherever the country rock is a gold-bearing one, the valuable ore may have passed into the streams with the other detrital materials, and, even though in very fine flakes, being yet very heavy has sunk to the bottom in the slacked water and has there enriched the gravel. The magnetic nature of the sands derived from this source is often due to the bed-rock, or to some bed of interstratified and impervious clay, and, if the latter is sodic, it is relatively rich. It favours also the insides of bends and the heads of quiet reaches. When a small tributary stream joins a larger one and is both checked and the current of the large one, the gold, as in the Klondike, tends to settle in relatively great abundance.

Auriferous stream-gravels, or related rock-cavities, often fail to yield the nuggets, apparently because the swirl of the water and grit has ground them to impalpable powder. The particles have then been washed elutriated to the nearest beach, where gold-bearing gravels are panned down a small residue is obtained of all the heavy minerals in the gravel. Magnetite is the commonest and gives the technical name of “black sand” to the deposit, and from this the gold is separated as the heavy mineral. If the stream has been hunted over by sportsmen with shot-guns or rifles, the lost shot and bullets are commonly caught in the pan. Even diamonds have been rarely noted and they may, indeed, be specially sought for in gravels.

Along sea-beaches where great beds of auriferous gravel have been attacked by the surf, concentrated bars carrying nuggets and flakes of gold have been formed. The payable quartz-rich gravels of Cape Nome, Alaska, is perhaps the most productive of all. The gold in the beach-placers is usually worn by the constant attrition into fine powdery form, and is there almost always found garnet and other less familiar minerals. If the stream has been hunted over by sportsmen with shot-guns or rifles, the lost shot and bullets are commonly caught in the pan. Even diamonds have been rarely noted and they may, indeed, be specially sought for in gravels.
